INDEX TO VOLUME XLVII

January 1 to June 30, 1918

EXPLANATORY NOTE

Illustrated articles are marked with an asterisk (*), book notices with a dagger (†), inquiries with a double dagger (‡). The cross-references condense the material and assist the reader, but are not to be regarded as complete or conclusive. So, if there were a reference from "Boiler" to "Power plant," and if the searcher failed to find the required article under the latter word, he should look through the "Boiler" entries, or others that the topic might suggest, as he would have done had there been no cross-reference. Letters are indexed under title or subject, general articles under writer's name as well. Not all articles relating to a given topic necessarily appear under the same entries.

Following is a list of the pages included in the several numbers of the volume, by date:

Jan.	1	Pages	1-38
"	8	"	39-72
"	15	"	73-106
"	22	"	107-140

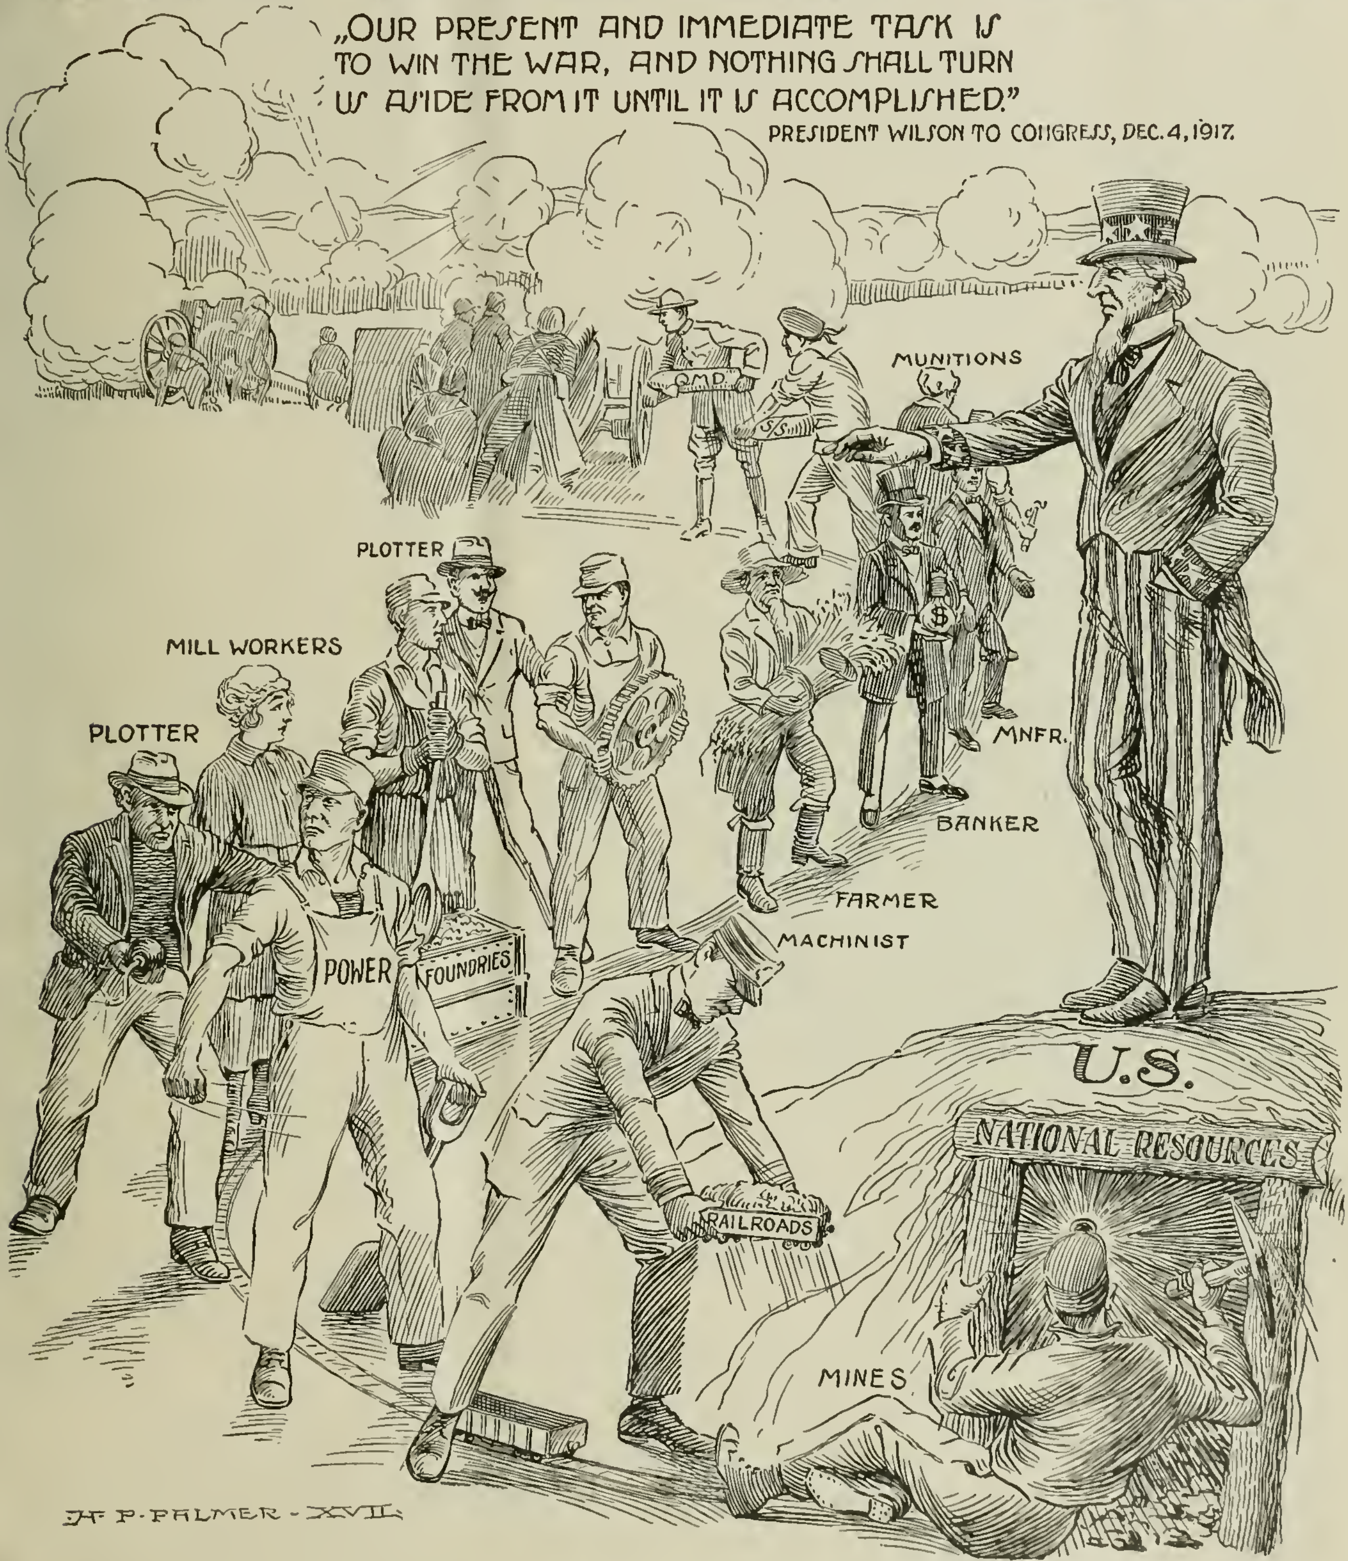
POWER

Vol. 47 NEW YORK, JANUARY 1, 1918 No. 1

THE VICTORY LINE

„OUR PRESENT AND IMMEDIATE TASK IS TO WIN THE WAR, AND NOTHING SHALL TURN US ASIDE FROM IT UNTIL IT IS ACCOMPLISHED."

PRESIDENT WILSON TO CONGRESS, DEC. 4, 1917.



The Year's Progress in The Power Field

DURING the last year war has been the one great factor influencing the power field. In certain branches it has brought forth intensive development (the "Liberty" motor, for example), but for the most part progress has been delayed. In the face of readjustment of labor due to the call of the army, shortage of coal and raw materials and inadequate transportation facilities, maximum production has absorbed largely the energy of the mechanical industry. There have been enormous demands for boilers, prime movers and auxiliary equipment for the numerous boats now building. To keep pace with the great output from the shops, power-plant capacity has been increased with a decided tendency toward the use of larger units. Comparatively small plants that not long ago considered machines of 5000-kw. capacity large, are now installing 10,000-kw. turbo-generators with the idea of larger machines on the next order. This has led to the use of larger boilers, stokers and condensers. Over a period of years there has been steady progress in this direction and a trend toward higher pressures accompanied by superheat of increasing degree. Back of this has been the demand for higher efficiencies, due to the rising price of fuel. For the same reason the economizer is no longer a doubtful investment, and impetus has been given toward improving the economy of all auxiliaries.

The Trend Toward Higher Pressures

With proper selection of available equipment and close attention to air leakage it is now possible to maintain a vacuum 97 per cent. perfect, leaving little to gain. At the upper end of the thermal cycle the opportunity for improvement is greater. With present materials and designs a maximum initial temperature of 700 deg. is considered the practical limit. Made up in the proper proportions by pressure and superheat, there is a possible 10 to 12 per cent. gain in economy over present results. Increase of friction with the density of the steam, the greater expansion and contraction and other practical difficulties detract from the previous theoretical estimate, but even a portion of the gain mentioned is worth striving for. Turbine builders see no insurmountable difficulties in perfecting their machines for the higher pressures. However, radical changes in boiler and valve design will be necessary. The pressure limit for the standard boiler has been placed at 350 lb., whereas 500 to 600 lb. is anticipated. Experimental work to develop boilers for these pressures is now in process. At the present time pressures up to 250 lb. are common, and during the last year a number of installations were made or planned in which the pressures will be higher.

Notable Steam Plants

At Joliet, the Public Service Company of Northern Illinois has cross-drum boilers designed for 350 lb. pressure and 225 deg. of superheat. This is the highest pressure used in a central-station plant in this country, and it is generally conceded that it is about the limit for boilers of the present standard design. In the same plant an innovation is the use of a horizontal all-steel individual economizer placed above and integral with the boiler, the whole being inclosed by a steel casing Although careful tests have not been made as yet, the boilers have been in operation long enough to indicate that they will develop exceptionally high capacities and that the efficiency may exceed 80 per cent.

To withstand the high pressure the plates of the boiler drum are 1$\frac{5}{16}$ in. thick and the longitudinal seam is a quadruple-riveted butt joint with double cover straps. The boiler tubes are of lower gage than in boilers designed for 250 lb. pressure, and the metal in the economizer tubes is one-quarter inch thick. Valves that had been previously designed for the pressure were available, the piping is extra heavy and the joints are of the bolted type having a welded seal commonly employed by Sargent & Lundy for high pressures. With smooth metal-to-metal joints, the difficulties that gaskets would cause are eliminated. At normal load a steam velocity of 7200 ft. per min. in the turbine leads is employed. This permits piping of comparatively small diameters, so that the initial cost is very little more than for pressures of 250 pounds.

Extensions to many plants have been made, and a number of new stations have been placed in operation during the year. Perhaps the most notable is the new steam station of the Buffalo General Electric Co. designed for 275 lb. pressure and 275 deg. of superheat, giving a total steam temperature of 689 deg. The station was planned for a capacity of 200,000 kw., but the initial installation was 60,000 kw. in three units. The boilers are of the cross-drum type having 11,400 sq.ft. of steam-making surface each. They are fired at both ends by two 15-retort underfeed stokers. This duplex stoker setting, measuring at the grate level nearly 24 ft. wide by 17½ ft. deep, is the largest ever built, and the ratio of grate area to heating surface, 1 to 27.3, is probably the most liberal employed in power-plant practice. At normal rating a trifle less than two tons of coal per hour is fed to each boiler. The stokers are capable of supplying 15 tons per boiler per hour, and when feeding 10½ tons per hour per boiler, which is well within easy operation, the rate of combustion is about 50 lb. per sq.ft. of grate and the evaporation per square foot of heating surface is 14.4 lb. When this is compared to three pounds, which is considered a fair figure for normal operation, it is evident the plant has been designed to carry overloads that would have been considered impossible a few years ago. To avoid difficulties with scale the makeup water is distilled. Valves in the high-pressure lines are of steel and of the gate type. In line with modern tendencies, duplex exciter units, with a motor on one end and a turbine on the other, are employed. An innovation tending to collect some of the stray heat units is the circulation of condensate for cooling the main turbine bearings.

Steam-Turbine Development

In the review last year was given a list of large turbines on order. Some of these were the 50,000-kv.-a. turbo-generator for Connors Creek, the 60,000-kw. three-cylinder unit for the Interborough, a 45,000-kw. turbine for the Narragansett Electric Lighting Co., of

Providence, and five 30,000- and 35,000-kw. machines for the Commonwealth-Edison Co. One of the 35,000-kw. units is shown in Fig. 1. The turbine is of the two-cylinder tandem-compound type, with the high-pressure element single-flow and the low-pressure element double-flow. To this list may be added a 45,000-kw. two-cylinder compound unit and a 70,000-kw. three-cylinder machine, the largest ever made, for the Duquesne Light Co., of Pittsburgh. Some of these machines have been installed and the others are still in the making. A close observance of their operation should go a long way in determining the status of the large turbine. Data will be collected that should decide the features of the various designs to be retained or modified, the best arrangement of the unit and the economical limitations.

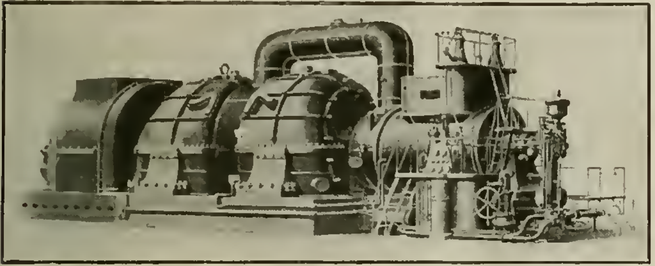


FIG. 1. WESTINGHOUSE 35,000-KW. TURBO-GENERATOR

Opinion has been expressed that the mammoth unit is perhaps after all a mistake. At least development should first come in designs for high pressure and intermediate heating of the steam to raise the average temperature. The various makers of turbines are working along different lines. Some are perfecting the impulse turbine and leaning toward a single-cylinder machine even in the largest sizes. Opposed to this is the reaction turbine with two and, in the largest machines, three cylinders. The present year should be significant in turbine development, as many great machines of either type will be placed in operation and there should be abundant data to point the way.

In the impulse turbine there is a noticeable tendency toward symmetrical cone-shaped construction, the elimination of angles and the production of a straight path for the steam. The early stages are becoming smaller in diameter and fewer to minimize the friction and leakage, which increase with the density and pressure of the steam, and better metals are being employed so that a high velocity of the blading may be maintained. The numerous control valves regulating the quantity of steam to the turbine have been replaced by a single throttle valve that for loads below normal lowers the pressure. This reduces the density of the steam and lessens the aforementioned losses without diminishing the heat content per pound. At the low end the stages are increasing in diameter to reduce the leaving loss to a minimum. In many of the late machines the length from the first to the last stage is less than the short diameter of the exhaust opening.

In the smaller units it may be stated that the turbine is rapidly replacing the reciprocating engine, even invading the small office-building plant. This is particularly true in the West. It requires comparatively small space and little attendance. There is no oil in the exhaust steam and reduction gearing permits economical speeds in different classes of work for both the prime mover and the driven machine. The turbine is even proposed for locomotive drive where with its high speed more power can be concentrated in the limited space available. The small turbine for auxiliary drive has been perfected and its economy improved. To make a combined pump or blower unit with less cost, weight and dimensions, a one-bearing turbine has been brought forth. It is incomplete in itself, but becomes an integral part of the over-all equipment.

Reciprocating Engines

Developments in the reciprocating engine have remained practically unchanged. However, the demand for marine engines has tended to accelerate the construction of this type. What is probably the most powerful rolling-mill reversing engine in existence was put in service during the year. Its cylinder sizes are 36 in. and 70 in., with a 60-in. stroke. The engine is geared and when running at its maximum speed is capable of developing more than 30,000 hp. if maximum torque occurs at the same time. However, they do not occur at the same time and it is doubtful whether the engine will ever be called on to develop more than 11,000 hp. The approximate weight is 1,350,000 pounds.

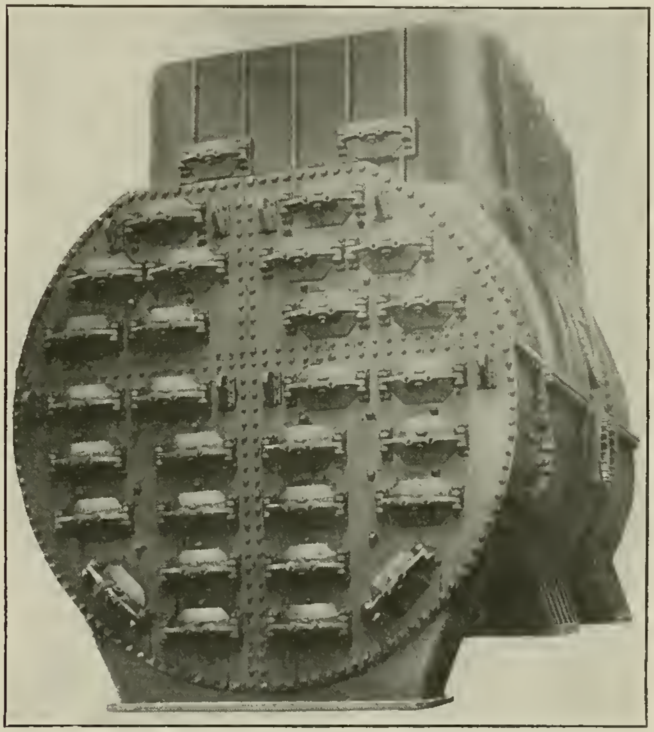

FIG. 2. WORTHINGTON SURFACE CONDENSER, 70,000 SQ.FT. OF ACTIVE TUBE SURFACE

Auxiliary Equipment

To take advantage of the low steam rates of the large turbines, the trend toward electric-driven auxiliaries has continued, steam drives, principally turbines, being maintained in lesser number to insure continuity of service and to maintain a proper heat balance. In some few cases this movement has been carried to the point of bleeding the main turbine to supplement the supply of exhaust steam to the heater. The lack of exhaust steam for feed-water heating due to the above practice has brought about almost universal adoption of the economizer in new plants.

Manufacturers report orders for geared units as opposed to the direct-connected turbine in the ratio of three to one. In operation the gears are standing up well and have been perfected to such a point that they make little noise. An interesting development is the use of large geared units for excitation, these machines being built in capacities up to 1000 kw. In these designs the turbine may operate at its most economical speed and the generator at the low speed necessary to insure perfect commutation.

Surface condensers are naturally following the turbine and getting larger each year. Up to date 70,000 sq.ft. of active tube surface in a single shell is the largest (Fig. 2), but there appears to be no good reason why this enormous capacity could not be increased. Condensing equipments for the 60,000- to 70,000-kw. turbines for the Interborough and the Duquesne Light Co. plants are to contain 100,000 sq.ft. of surface, but it is to be disposed in four shells. Among large jet condensers the installation at Providence serving a 45,000-kw. turbine still holds the record. The outstanding feature of the year in all condensing equipment has been the unprecedented volume of business. In surface condensers there has been a tendency to increase the water pumped per pound of steam. It is also becoming apparent that, although the highest vacuum obtainable is to be desired, it should not be produced with an accompanying drop in the temperature of the condensate below that called for by the vacuum.

Some interesting developments in air pumps have been made. Maurice Leblanc, inventor of the hydraulic air pump quite universally used for turbines, has improved upon this centrifugal type by bringing forth the *multijector*. No revolving parts are employed, vacuum being produced by steam passed through a number of nozzles to give injector effect. As expected, this type takes up much less room than the well-known Leblanc air pump for like capacities. An interesting description of the *multijector*, together with recent air-pump-design progress, will appear in an early issue of *Power*.

LARGER STEAM BOILERS

War demands have so overloaded the boiler manufacturers as to hinder and for the time being practically stop development. For the last few years there has been a gradual increase in unit size, but the growth has not kept pace with that of the turbine. In the last year, however, a boiler unit commensurate in size with the larger turbines has been developed. It is known as the Stevens-Pratt boiler, and is made up in four sections, each being a complete Babcock & Wilcox cross-drum boiler in itself, with its own superheater economizer and forced- and induced-draft fans. There are two sections on either side, the boilers being placed back to back. One stack serves the unit, and the coal- and ash-handling equipment is common to the two sections on the same side of the unit. If desired, any one or more of the sections may be operated independently. The sections are made in sizes ranging from 5000 to 14,500 sq.ft. of heating surface. Four of the largest sections operating at 400 per cent. of rating will carry 58,000 kw. This is equivalent to carrying one kilowatt on one square foot of steam-making surface as compared to four square feet at normal rating. That this arrangement is compact is evidenced by the fact that the unit occupies 7632 sq.ft. of floor space. It avoids an elaborate boiler-room building, as, with the exception of the coal bunkers, the unit is complete in itself.

STOKERS AND PUMPS

Shortage of fuel and its increased cost has resulted in the use of coal heretofore considered unfit for burning. Anthracite screenings and coke breeze, frequently mixed with bituminous coal, have presented new problems in connection with the underfeed stoker. Naturally, the chief difficulty is to dispose of the large amounts of refuse when forcing the boilers to high capacity. Improved ash dumps are proving a solution, some operated by power and others by hand, but all designed to handle greater quantities. In addition, the underfeed stoker is being adapted to burn the high-ash Middle West coals and lignite. Some installations have already made their appearance and have been giving good results.

To burn great quantities of anthracite the duplex stoker is becoming more common. With no bridge-wall and an adjustable opening between the stokers the continuous discharge of ashes is readily accomplished. With coal fed slowly through the retorts and a great quantity carried in the furnace, conditions are favorable for high combustion efficiency. To burn more fuel from one side of the setting and obtain the high boiler ratings now in vogue, increasing the size of the retort is another alternative. Designs are now ready in which the retort area has been enlarged 50 per cent. over present standards.

On the part of several builders there have been persistent attempts to apply forced draft to a chain grate. With a moving stoker, subject to the varying density of fuel bed common with bituminous coal, the problem has proved difficult and its solution so far unsatisfactory. With anthracite more headway has been made, as evidenced by the Cox chain grate, which shows considerable promise.

In boiler-feed pumps an interesting development in the direction of compactness and simplicity is the placing of a two-stage centrifugal pump in one casing and on a common shaft with a velocity-stage turbine. The unit will serve 3000 boiler horsepower, and with one-tenth the weight occupies about one-eighth the floor space required by a duplex reciprocating pump of the same capacity.

Another interesting development given publicity during the year is the use of two centrifugal pumps driven by one turbine for economizer service. Ordinarily, the pressure in the economizer is slightly greater than in the boiler, and with the pressures increasing as they have recently, it places a serious burden on the economizer. This may be relieved by using two pumps, one taking the feed from the heater and passing it through the economizer at comparatively low pressure, the other taking the water under pressure from the economizer and forcing it into the boiler. Under such conditions even old economizers could be used with safety in conjunction with high pressures.

As the boiler pressure goes up steam velocities have been increasing. At the Joliet plant the velocity at normal load in the turbine leads is 7200 ft. per min. There are instances in which this velocity has been exceeded and velocities 50 per cent. greater have been proposed. Such practice tends to reduce pipe diameters and minimize the cost of pipe-line construction. As the density of the steam increases, friction becomes greater and there is considerable pressure drop in the pipe line, which in turn reduces the capacity of the prime mover. When these two factors have been properly correlated, it may be found advisable to spend more money for larger pipes and fittings.

The increasing cost of coal and the concentration of power in larger units has resulted in more extensive use of instruments, particularly those of the recording type, in the boiler room. New instruments and combinations of older types are constantly making their appearance, so that the fireman in these days has the advantage the engineer has enjoyed for years.

INTERNAL-COMBUSTION ENGINES

Opinion seems prevalent that there is little or no activity in the gas-engine field. In smaller sizes of engine this is undoubtedly true, but there are now in course of construction a considerable number of large gas engines for at least four of the largest steel mills in the country. Some of these engines will exceed 4000 hp. and will be used for blowing and for driving electric generators. Fig. 3, although not as large as some of the blowing engines now under construction, is a fair example of what is being done. The dimensions of this engine are 84 x 60 in. on the air end and 46 x 60 in. on the gas end. It would look as though this type of prime mover is not ready to be forced into oblivion, although the steam turbine is now pushing it hard and, owing to its economy over a wide range of load, may eventually be the favorite for steel-mill work.

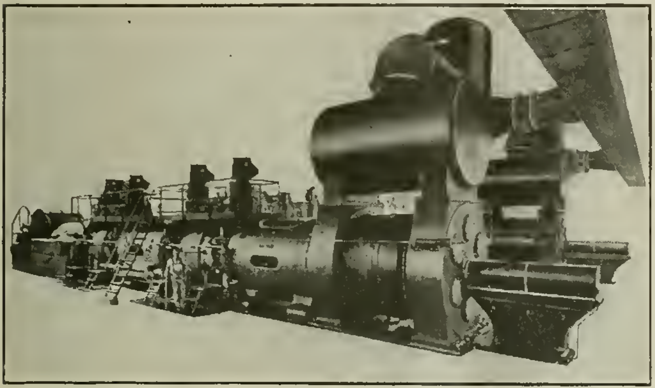

FIG. 3. MESTA TWIN-TANDEM GAS BLOWING ENGINE

Manufacturers of Diesel and other types of oil engines are working to the limit of shop capacity. Because of the high cost of fuel and the need for power by the industries, a surprising number of Diesel engines have been installed, some of them having capacities of 1000 hp. Demands for these engines in the South and Southwest still continue at an increasing rate, and on the Pacific Coast the marine field is apparently flourishing. Several firms that heretofore have built only stationary engines have lately brought out marine types. The entire output of at least two of our largest Diesel engine builders has been devoted to Government orders (for submarines) since the United States entered the war. A new design of high-compression four-cycle heavy-oil engine has been brought forth, and details of existing engines have been perfected.

Large numbers of gasoline and kerosene engines are being used by our forces in France for searchlights, portable lighting outfits, for driving compressors, for small repair outfits, etc. These are of the carburetor type, but are designed to use either gasoline or kerosene. For airplane service the "Liberty" motor has been one of the great accomplishments of the year.

POWER-PLANT LEGISLATION

Legislation relative to power plants has been active throughout the year despite the war. The Boiler Code of the American Society of Mechanical Engineers is now in force or about to be enforced in the following states: California, Ohio, Michigan, Wisconsin, Minnesota, Indiana, Pennsylvania, New York and New Jersey. Many other state legislatures favorably regard the Code; but other more pressing legislation or lack of financial resources prevented the adoption of the Code in these states.

The Municipal Regulations Committee of the American Society of Refrigerating Engineers has made favorable progress in the formulation of a safety code for refrigerating plants and by December, 1918, will likely hand to the society a finished code. The City of Troy, N. Y., now enforces a code drawn up with the assistance of this committee.

There has been little activity in the enactment of engineers' and firemen's license laws. The rules of the Board of Supervising Inspectors of Steam Vessels have been modified for the purpose of facilitating the entrance of men into marine service, particularly under the Shipping Board, though there are, it seems, obstructionist forces at work to wholly or partly defeat the purpose. Some interesting water-power legislation may come during the present Congress.

COAL, OIL FUEL AND SMOKE

Up to the end of September the bituminous-coal production for the country exceeded that for a corresponding period in 1916 by 10.5 per cent. This increase has been approximately maintained up to the end of the year, and it means about 50 million tons in excess of the 500 million produced in the previous year. More anthracite also has been mined, but notwithstanding this immense production there has been a decided shortage of fuel. Its delivery, depending upon congested railway facilities, was irregular, and to shorten the haul many users were obliged to accept the coal nearest at hand. Owing to the higher prices attempts were made to use in part inferior grades of fuel, such as culm, coke breeze and lignites, with varying degrees of success. The uncertain conditions caused many fuel users to consider storage, laying up a supply during the summer months when the demand is lightest and transportation at its best, to tide them over irregular deliveries during the heating season. In the last year, then, more than ordinary attention has been given to coal-handling apparatus, storage and the weathering of coal. Federal fuel administrators are doing everything in their power to encourage economy. It is realized that up-to-date firing methods and general improvement in operating conditions will save millions of tons of coal per year.

Oil fuel for power plants has come into extensive use even in New England, where under ordinary conditions it would not be considered. This has been due to the upsetting of transportation by rail and by water, the excessive cost of coal and its actual scarcity. In the year just closed the production was considerably in excess of that of 1916, which was 292,300,000 bbl., the greatest record in the history of petroleum.

Smoke abatement has been set back temporarily. The smoke in Chicago was never worse. New York is receiving its baptism of soot and ash from the burning of soft coal in furnaces designed for anthracite. Boston is in much the same situation, and even in Pittsburgh, where smokeless history has been made in recent years, conditions are not up to standard. Naturally, this is due to changes of fuel, the burning of inferior grades and the calling into service of boilers that have not been remodeled for smokeless operation. With the gradual readjustments that economy will demand the smoke situation will undoubtedly improve.

THE REFRIGERATION FIELD

Perhaps the most noteworthy progress in the refrigeration field during the year is the wide adoption of the high-speed compressor, using the thin-plate valve, or feather valve. One large and oldest company manufacturing refrigerating machinery has been turning out many high-speed compressors, not an order for a slow-speed machine having been received during the first half of its fiscal year. Other manufacturers are experiencing similar business orders in relation to the high-speed compressor.

Electric drive, particularly for compressors used for ice making, is receiving ever-widening application, especially in Chicago and New York.

The new refrigerating plant of the Merchants Refrigerating Co., New York, is of unusual interest. The compressors are of the York, three-cylinder, single-acting, piston valve, inclosed type, driven by synchronous motors of special design. The efficiency of these motors is stated to be 90 to 94 per cent., the starting torque 35 per cent. and the "pull-in" torque 30 per cent.

The installation has four units, a 50-ton (234 r.p.m.), a 100-ton and two 200-ton, the three latter running at 209 r.p.m. They are to be operated at 3 lb. back pressure and 155 lb. condenser pressure. They will operate compounded; that is, two cylinders of each machine will take in low-pressure gas and the other cylinder of the compressor will take this gas and boost it to the condenser pressure. After leaving the receivers, the liquid will go to a double-pipe cooler, where water will take out the sensible heat to within 1 deg. F. of the initial water temperature. The liquid then will go to accumulators, where its temperature will be reduced to the boiling point at the intermediate ammonia pressure. The vapor will be taken directly into the high-pressure cylinder. The piping is so arranged as to permit of operating either single or compound compression. All shells, including those of brine coolers, shell condensers, etc., are autogenous (oxyacetylene) welded. A more complete description of the plant will, it is hoped, soon appear in *Power*.

The booster compressor is exciting much comment, and the Ninth Street Terminal, Chicago, is a new and interesting installation. The plant has but recently been started, and performance data are not yet available. The new installation at the Consumers Ice Co., Chicago, is one of the first of the D. I. Davis low-temperature compression systems. A description of this plant is now ready for appearance in *Power*.

Welding, of course, continues to be of keen interest to refrigerating engineers, and it is cheering that all the various interests have formed the National Welding Council, which so far has displayed a most sincere and unprejudiced attitude in its aim to make autogenous welding safe for pressure vessels.

The first section of the American Society of Refrigerating Engineers has been instituted in New York City, and its success will probably lead to the organization of other sections in the large cities.

THE WATER-POWER SITUATION

Although the unfortunate condition of water-power legislation still remains unsettled, there has been considerable activity in the construction of new plants and extensions to existing installations. The Copco, California, plant for the Southern Pacific is nearing completion. It will have an initial capacity of 25,000 hp., which later will be increased to 50,000 hp. by a subsidiary station. The Southern California Edison Co. has announced that it will shortly add 42,500 hp. to its capacity at Big Creek and make further additions to the plants served by Huntington Lake.

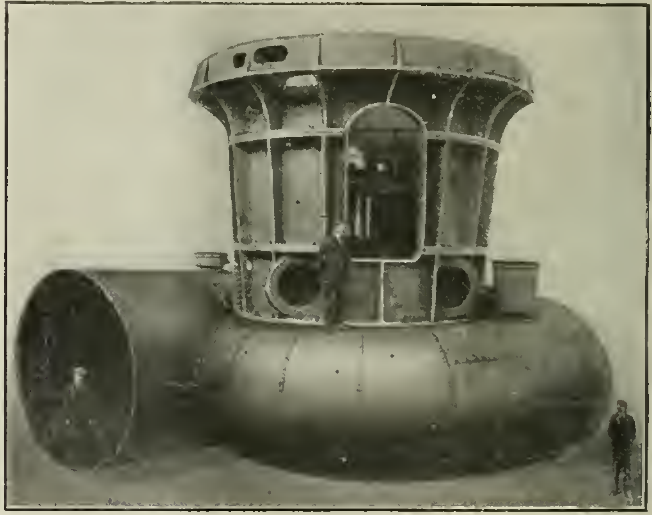

FIG. 4. S. MORGAN SMITH PIT LINER AND SCROLL FOR 16,500-HP. VERTICAL-SHAFT TURBINE

The Puget Sound Traction, Light and Power Co., is installing 25,000 hp. additional capacity in its White River Power Plant near Sumner, Wash. The Montana Power Co. is installing four 16,500-hp. single-runner vertical-shaft Francis type turbines in its Holter plant. The steel-plate scroll, the intake diameter of which is 12 ft., and cast-iron pit liner for one of these units are shown in Fig. 4. These machines will operate under a working head of 109 ft. and run at 150 revolutions per minute.

Work has continued on the 31,000-hp. single-runner vertical turbines for the Yadkin River development in

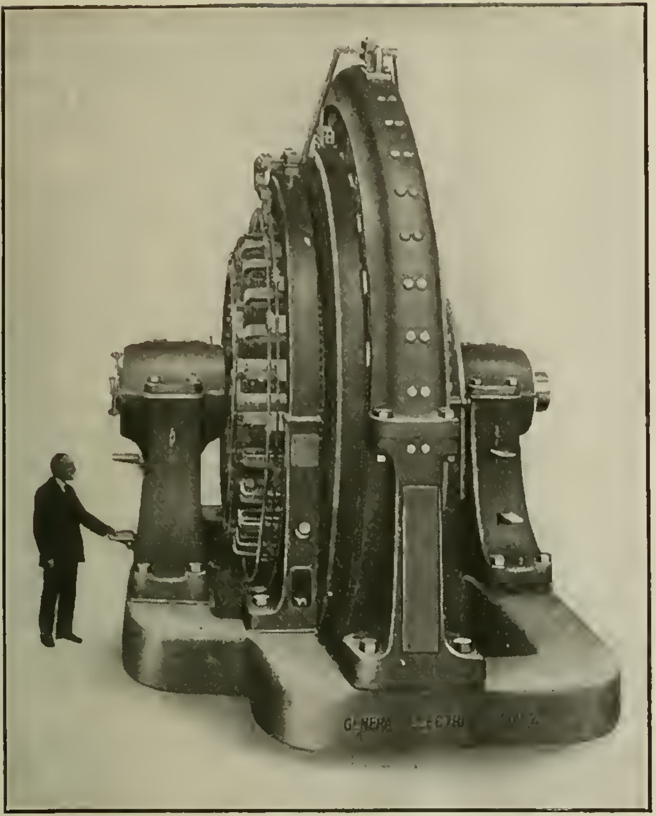

FIG. 5. GENERAL ELECTRIC 6825-KW. 25-CYCLE ROTARY CONVERTER

North Carolina, and numerous other large installations might be mentioned. Owing to the great power demands and the higher cost of fuel, several hundred thousand horsepower has been added to "white-coal" capacity during the year. In the way of improvements may be mentioned simplification and standardization of governors, development in runner design and reduction of hydraulic losses in intake and draft tubes.

Acquisition of the properties of the Ontario Power Co. by the Hydro-Electric Commission of Ontario was a significant step toward governmental participation in developing natural resources. When the Chippewa Creek-Queenstown Heights developments are completed, the commission will be the largest producer of water power in the world. Its work will be watched with interest in this country, as the adoption of a similar plan may be the solution for the existing controversy in this field.

Electrical Development

During the last year there has not been any marked change in the electrical industry over that of 1916. The manufacturers have been practically overwhelmed in trying to meet the demands on the industry for standard equipment, consequently the development of new types of machinery has been subordinated to these demands. However, a number of the large machines that were projected in 1916 were built and installed during 1917. Others again are still in the construction stage, as pointed out in the foregoing, in reference to the large turbine unit.

During the year 25-cycle rotary converters up to 6825-kw. capacity, Fig. 5, have been put in operation, and 60-cycle machines up to 5800 kw. in size have been installed. These machines are the largest of either type that have so far been built. One of the most important advances in the construction of self-controlled induction feeder voltage regulators is the 600-kv.-a. three-phase 60-cycle 13,200-volt unit, Fig. 6, installed by the Southern Power Co., to be connected to the low-voltage side of a 6000-kv.-a. bank of 44,000- to 13,200-volt transformers. This unit is equipped with radiators on the tank for cooling purposes similar to those used on self-cooled transformers.

The most interesting transformer unit of the year is probably the 44,000-volt to 6000-volt, 8000-kv.-a. oil-insulated self-cooled unit, Fig. 7, six of which were built for the Carnegie Steel Co. The radiators are constructed of a number of vertical flattened tubes welded into headers, which are flanged and bolted to the tank. The 24 radiators on each tank give an effective cooling surface of approximately 1,000,000 sq.in. Oil-insulated water-cooled units of over three times the foregoing capacity are under construction or being installed.

The Pacific Light and Power Co. has installed in its Eagle Rock substation at the end of a transmission line 241 miles long, a 15,000-kv.-a. synchronous condenser, Fig. 8. This is used to maintain constant voltage at the receiving end of this long transmission line, which is operated at 135,000 volts with grounded neutral at the power-house end. Before the condenser was installed, the no-load voltage at the receiving end was 211,000 volts. With the condenser in service the voltage at the receiving end of the transmission line is held practically constant under all conditions of load.

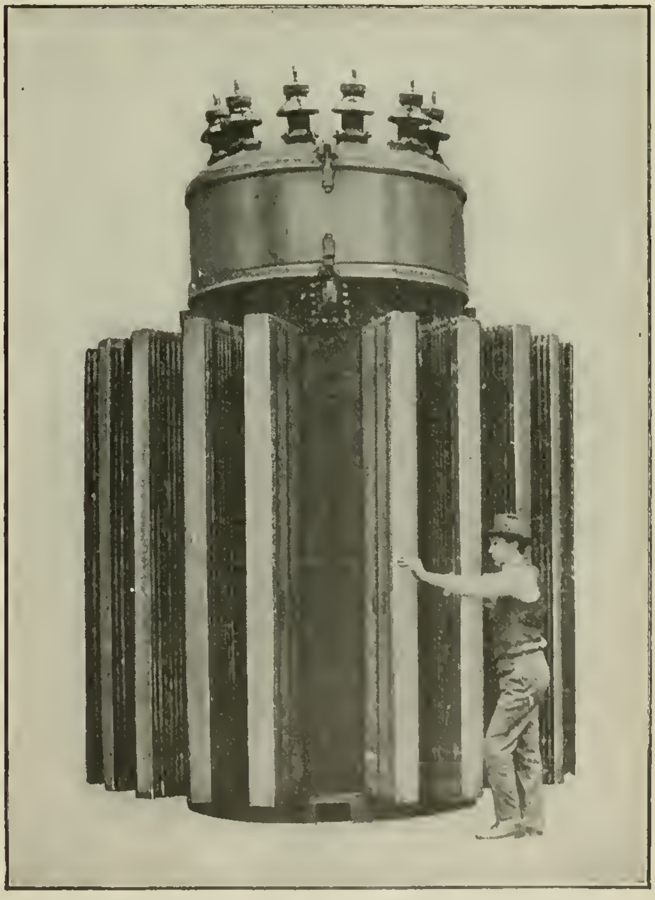

FIG. 6. WESTINGHOUSE 600-KV.-A. 3-PHASE INDUCTION FEEDER VOLTAGE REGULATOR

In the steel industry the application of electricity has continued to make rapid advances. Two of the chief applications are of reversing motors for rolling-mill main-roll drives and the electric furnace. There is in use at the present time approximately 690,000 hp. of main-roll drives in the United States, an increase of 400 per cent. during the last five years. These drives require very large motors. The reversing blooming-mill unit shown in Fig. 9 is one of the largest direct-current single-unit motors that has so far been built. It has a momentary rating of 10,000 hp. at 40 r.p.m. The machine is fully compensated and is shunt-wound. In spite of its great size, it can be accelerated at the rate of 50 revolutions per second. The motor is supplied with power from a flywheel motor-generator set, consisting of a 2000-kw., 500-volt generator, driven by a 2200-volt 2000-hp. induction motor. The flywheel weighs 100,000 pounds.

The vast increase in the use of electrical furnaces is evidenced by the fact that in this country, Jan. 1, 1916, there were 36 furnaces in use, having a capacity of 191 net tons, and requiring 90,000 kv.-a. At the present time the capacity has increased to approximately 1000 net tons requiring about 230,000 kilovolt-amperes.

The 250,000-kw. totalizing graphic meter, Fig. 10, built for the Keokuk plant of the Mississippi River Power Co., is the largest meter ever constructed. The instrument will give a graphic record of the output of the thirty 3-phase, 7500-kw. generators to be installed ultimately in this plant. To accomplish this thirty polyphase-meter elements, each made up of two single-phase units are used. The induction type of meter element is employed. The moving element consists of six aluminum vanes, all supported on a single shaft. All connections are carried to the top of the instrument to a circular terminal board having 240 binding posts. The chart is 12½ in. wide and printed in 12-hour sections and feeds at the rate of 3 in. per hour.

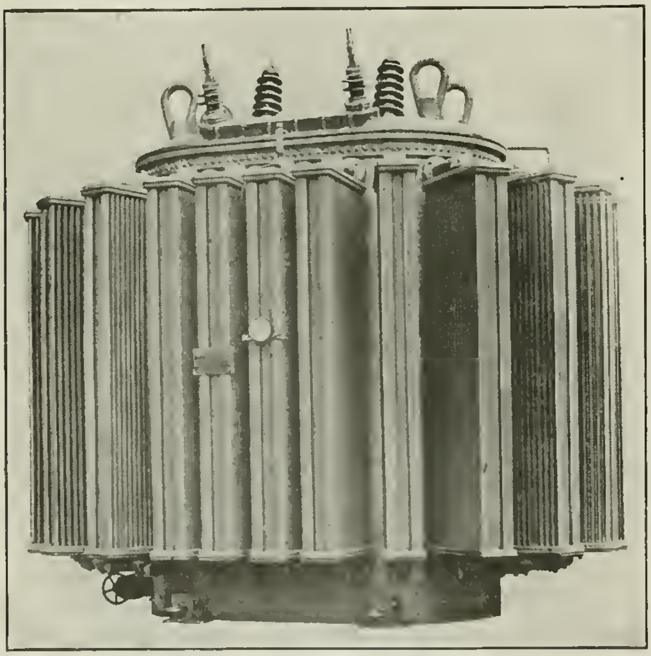

FIG. 7. GENERAL ELECTRIC 6000-KV.-A. OIL-INSULATED SELF-COOLED TRANSFORMER

Owing to the expansion of our industries, much of which came suddenly and is considered more or less temporary, there has been a great increase in the demand for power. Generating equipment, except on long deliveries, was almost impossible to get, with the result that the central station has been swamped in trying to supply a considerable portion of the excess power requirements. With the manufacturer it has not been so much a question of cost as obtaining quickly the power he needed to turn out war products. There is still a great deficiency in prime-mover capacity, and to improve this condition it has been suggested that private plants tie in with the central station, helping it out on the peak load and in turn taking current from it in the valleys, but standing by as reserve capacity needed in case of breakdown.

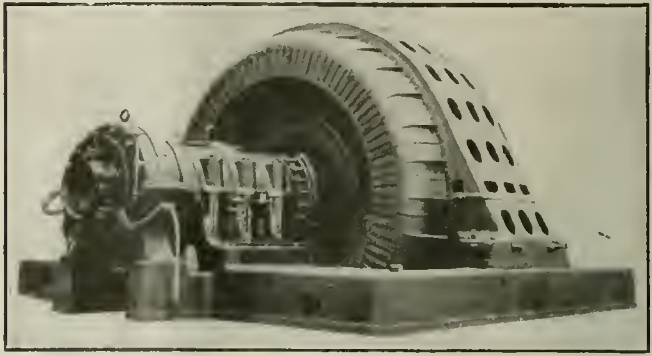

FIG. 8. WESTINGHOUSE 15,000-KV.-A. SYNCHRONOUS CONDENSER

Shortage of coal has aggravated the situation. It has instigated a great campaign for saving. By state fuel administrators, committees have been appointed to investigate the possibilities and to interest owners of private plants in this movement. The fireman is being flooded with instructions, and publicity committees are arranging for space in the press and competent lecturers, preferably engineers, to point out the many possibilities of saving in the private plant and the home.

Increase in the price of coal tends to enforce better economy in all stations, private and central. To meet the great demand for power and for economy in the use of coal it would appear that the time is ripe for readjustment. There is many a private plant taken over by the central station that could be operated more economically on its own basis. It could produce the power, light and heat needed with an expenditure of coal less than the independent electric and heating services now require. There are some private plants of which the reverse is true. The exigencies demand careful, unbiased analyses to determine in each case what is best for the common good.

Engineering Societies

The campaign that has been conducted for the last few years showing the need and the desirability of coöperation among engineers is at last bearing fruit. The demands of the war have hastened the movement. The Engineering Council of the United Engineering Society has recently come into being as a medium of coöperation between the four big national engineering societies. It is made up of five members from each body and four from the parent organization. The council has authority to speak on all questions of concern to engineers. Realizing that at present the big thing is war work, the council has organized a "War Committee of Technical Societies," which has been coöperating in every way possible with the Government. The American Boiler Manufacturers' Association has appointed a war-service committee to act as a point of contact between the industry and the Government, and practically every engineering association in the country has offered its services in one way or another.

Coöperation between the local sections of the various societies is also improving. Joint meetings, dinners and entertainments are becoming the rule. In this connection it might be added that plans are on foot for a building to house all engineering societies in Chicago. This in reality is to be an engineering headquarters second only to New York.

The American Society of Mechanical Engineers continues to conduct work of inestimable value to the field. The Boiler Code, now adopted by nine states and four cities, is being perfected and interpretations are sent monthly. The safety-valve regulations are in process of revamping, and the question of welding is receiving attention. In its visit to the Chicago section, the Council has initiated a practice contributing toward the nationalization of the society by eradicating the too-prevalent idea that much of the benefit of membership centers in New York. These visits are worth continuing.

A progressive step by the National Association of Stationary Engineers at its last annual convention was the setting aside of definite periods for welfare talks by the delegates dealing with their work and improvement of the organization. The society is devoted primarily to education, but heretofore much of the national convention has been taken up by routine business. The innovation was heartily approved, and it is safe to predict that each year will see more of the time of the convention given over to the watchword of the association.

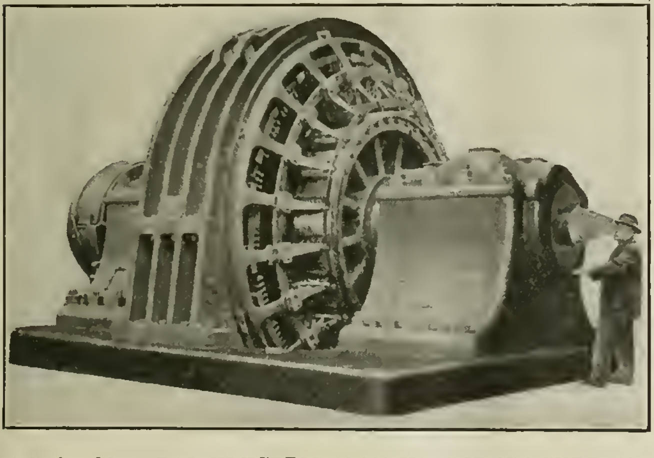

FIG. 9. GENERAL ELECTRIC 10,000-HP. DIRECT-CURRENT, REVERSING BLOOMING-MILL MOTOR

THE HONOR ROLL FOR 1917

For 1917 the honor roll is long and it is made up mostly by engineers engaged in the war, some in important work at home and others at the front. Of the latter many have already shown that they deserve high places in the list. For engineering achievement in private work mention should be made of Nikola Tesla, awarded the Edison Medal for original work in polyphase and high-frequency electric currents. Dr. Henry Marion Howe received the John Fritz medal for his investigations in metallurgy, especially in the metallography of iron and steel. Five gold medals were awarded by the American Museum of Safety for noteworthy achievement in the realm of safety.

Engineering societies closely related to the field honored the following men by election to the presidencies: Charles Thomas Main, American Society of Mechanical Engineers; E. W. Rice, Jr., American Institute of Electrical Engineers; J. W. Lieb, National Electric Light Association; John A. Wickert, National Association of Stationary Engineers; Ezra Frick, American Society of Refrigerating Engineers; Irwine J. Lyle, American Society of Heating and Ventilating Engineers; G. W. Martin, National District Heating Association.

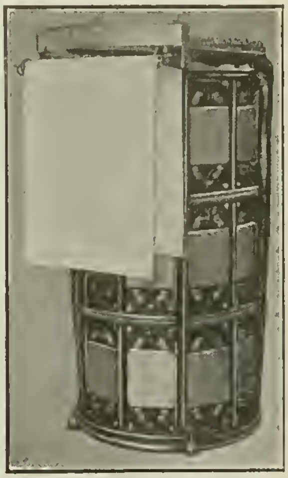

FIG. 10. ESTERLINE TOTALIZING GRAPHIC METER

NECROLOGY

It is pleasing to report that men of prominence in the field who passed away during the year were few in number. The columns of *Power* record the following: Alfred Blunt Jenkins, of Jenkins Brothers; Henry Gordon Stott, superintendent of motive power of the Interborough Rapid Transit Co.; George Ross, president of the Ross Valve Manufacturing Co.; James Terry, president of the Terry Steam Turbine Co.; Frank Lewis Bigelow, president of the Bigelow Co.; William G. Bee, vice president and general sales manager of the Edison Storage Battery Co.; James Fulton Cummings, an electrical engineer of international reputation: Albert F. Ganz, professor of electrical engineering at Stevens Institute of Technology; Arthur Kneisel, treasurer of the American Association of Engineers; Royal C. Peabody, president of the Combustion Engineering Co.; William P. Hancock, superintendent of the generating department of the Edison Electric Illuminating Co. of Boston; James F. Meagher, former president of the People's Gas, Light and Coke Co., of Chicago; George Harrison Klumph, late Western manager of the Green Fuel Economizer Co.; William D. Kearfott, president of the Kearfott Engineering Co.; Benjamin Murray Plumber, president of the Main Belting Company; Joseph F. Chuse, founder and manager of the Chuse Engine and Manufacturing Co.; Thomas Eugene Byrne, vice president and chief engineer of the Kings County Lighting Co., Brooklyn, N. Y.

Petroleum residual oil as fuel for Diesel engines is so scarce in the British Isles that users have had to adopt tar oil. They were just getting along nicely when the Minister of Munitions up and restricted the use of tar and other oils. And yet the "business as usual" howlers say there is plenty of fuel of all kinds.

New Method of Increasing the Evaporation in Boilers

By CARL HERING

A new thermal principle in the boiling of water is described. The thin film of gas on the flame side of a water-boiling vessel offers an enormously high resistance to the flow of heat. By means of lugs on the flame side of surface an artificial thermal resistance is established, which greatly increases the flow of heat, provided these lugs are properly proportioned.

IT IS well known that water may be boiled in a cup made of ordinary paper; also that a postage stamp may be pasted on the flame side of a metallic vessel in which water is being boiled and although the flame plays directly upon this stamp it will not be charred. It is perhaps less well known that when a second or third stamp is pasted over the first one, the outer ones will char. If there is a blister in a single thickness of the paper, that blister will char.

Gas Film on Flame Side of Vessel

The interpretation of this is that when very hot gases, like those of a flame, impinge upon the outside surface of any water-boiling vessel, which is constantly maintained at a far lower temperature by the water on the other side of it, a thin film of gas forms on the flame side of the surface which offers an enormously high resistance to the passage of heat through it; its specific resistance appears to be far greater than that of thermal insulators, yet all the heat which flows usefully from the flame to the water must traverse it; this film is therefore a very great obstruction to the flow of heat, and this method of heating is a very irrational one, although it is the usual way. The thermal resistance of the metallic walls of the vessel is so small in comparison that there is no appreciable gain in the heat flow by using copper tubes in a boiler in place of iron ones, even though copper conducts heat much better than iron.

If the temperature of the flame is taken at about 1350 deg. C. (2462 deg. F.) and that of the water is 100 deg. C. (212 deg. F.), there is a fall of temperature of about 1250 deg. C. through this film, which appears to be only about 0.005 in. thick; this means an extremely high thermal resistance, so high that it is a question whether it is a true resistance; but as it certainly acts like one, it may at least be here referred to by this term.

If this high-resistance film could be broken down, the heat would flow more rapidly from the flame to the water, which means that the water could be boiled faster or that the boiling vessels, like steam boilers, could be made smaller for the same steaming capacity; also that the losses of heat would be reduced, for if a given quantity of water could be boiled twice as fast, for instance, with the same flame, the heat losses will be reduced to a half, as they take place during only half the time.

One way to reduce the resistance of this film is to use a blast flame, which seems to mechanically carry away part of the film; a strong blast flame directed against the aforementioned postage stamp will char it; but this method is not generally practicable. The usual way is to increase the surface exposed to the flame, but doubling or trebling this surface while using the same flame does not necessarily double or treble the heat flow; if the volume of the flame is then also doubled or trebled, the amount of boiling will, of course, be increased proportionately, but this simply means doubling or trebling the whole boiler; this increases the quantity of heat transmitted but not the rate; nor does it increase the efficiency very much.

By studying the nature and properties of this high-resistance film the writer found that its resistance diminishes very rapidly when there is less difference of temperature between its two sides; namely, between the flame and the metal. In boiling molten zinc, for instance (about 950 deg. C.), instead of water, the resistance of this film would be very greatly reduced. It is probably also very slightly less in high-pressure boilers in which the temperature of the water is higher.

It seems to be analogous to the case in mechanics in which a heavy weight struck by a sharp blow will move only slightly, but when the same energy is exerted on it less violently, the body will be moved more freely by it; the resistance of the body against being moved (due to its inertia) becomes greater as the suddenness of the blow increases. Our present method of heating water may be said to be analogous to moving a heavy car by applying sharp hammer blows at the rear, in which case its inertia acts like a high resistance; this analogy, however, is only approximate.

Establishing Artificial Thermal Resistance

As the temperature of the flame is fixed, and it would be inadvisable to reduce it, and that of the water cannot be raised, there remains only increasing the temperature of the flame side of the vessel or boiler tube. This can best be done by interposing a thermal resistance between the flame side of the vessel and the water side, such that the flame side may become far hotter than the water side, say a red heat. The writer's researches have shown that when the usual flame impinges on a surface that is artificially maintained at a very much higher temperature than boiling water, say a dull-red heat, the resistance of this film is very greatly reduced; and that the artificially added resistance required to do this is far less than that of the film was, hence there is a great reduction in the total resistance and therefore a great gain in the flow of heat. It is a curious case in which the adding of still more thermal resistance in the path of the flow of heat diminishes the total resistance greatly. In mechanics a spring may in some respects be likened to a resistance to an opposing force, yet the addition of a spring between a violent push and a heavy body helps to overcome that effect of the inertia by which it acts like a high resistance.

These thermal relations are illustrated diagrammatically in Fig. 1. Let the vertical distances represent the thermal resistances in the path of the current of heat from flame to water, and the horizontal distances the temperatures of that side of the vessel which is exposed to the flame; that is, the side on which this film forms. The curve *a* then shows approximately how the resistance of the film diminishes as the temperature of that surface is increased.

To produce this increasing temperature on the flame surface, the added artificial resistance must be increased, as the water side always has the same temperature. The curve *b* represents approximately the respective artificial resistances which must be introduced to produce these increased temperatures. The total resistance, which is what governs the resulting flow of heat, will then be the sum of the ordinates of these two curves, giving a curve approximately like *c*; this curve shows that as more artificial resistance is introduced the total resistance falls, at first very rapidly, then reaches a minimum point and then rises again. The flow of heat will therefore first increase rapidly, reach a maximum, then fall again, showing that there is a point at which it is no longer advantageous to further increase this artificial resistance. The present researches indicate that this point seems to be reached when the temperature of that surface is about midway between that of the flame and that of the water; hence for water boiling this would be about 725 deg. C., which means a dull-red heat. This condition means that the drop of temperature in the artificial resistance is then equal to that in the film.

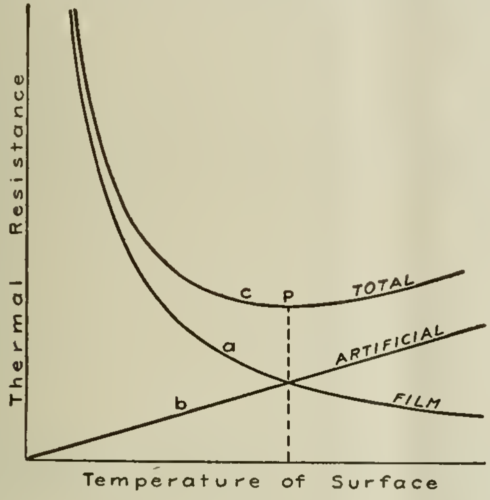

FIG. 1

FIG. 1. RELATIONS OF THERMAL RESISTANCES

A practical way to introduce this artificial resistance is by means of lugs on the flame side of the surface, which have such a length and diameter that the heat flow through them will maintain their hot ends at about a dull-red heat. In the writer's tests with lugs of the same diameter and increasing lengths, the flow of heat through them at first increased as they were made longer, and then diminished again after a certain length had been exceeded, thus corresponding to the curve *c*. When too long, their ends were at a bright-red heat.

It is an interesting and instructive experiment to solder some small nails or tacks with their heads against the outside of the bottom of a tin cup, then apply a large bunsen flame and notice how quickly and violently the water will boil directly over those nails as compared with the boiling over the rest of the surface of the cup. These lugs may be said to be a means for piercing this high-resisting film, allowing the heat to rush rapidly through these thermal openings.

The same thermal resistance may be produced by a long thick lug or by a shorter but thinner one, provided the ratio of the length to the cross-section is the same; and the quantity of heat flowing through each lug will of course diminish with its cross-section. Theoretically, therefore, the best condition would appear to be one lug of the diameter of the bottom surface of the vessel, or in other words, a very thick bottom, or very thick-walled boiler tubes. But it will be found that this thickness (corresponding to the length of the lug) would then have to be several feet, making this form of the resistance absurdly impracticable. The other extreme would be to have innumerable very thin short lugs, close together; this is impracticable on account of the expense, the frailty of such thin lugs, and the fact that when maintained at such a high temperature they gradually burn up. Between these extremes there are mean proportions which give the best results, considering the practical conditions.

EFFECTS OF VARYING SPACING AND SHAPE OF LUGS

Other effects are also involved. By spacing the same size lugs farther apart, the greater freedom of the circulation of the hot gases between them was found to increase the flow of heat through each lug, but as there were then less lugs per square inch of surface, the total heat flow in the vessel as a whole was less. It appears that the film is destroyed, or at least reduced, along the lateral surfaces of these lugs also, as the gases reaching the cooler parts are themselves cooler; hence the lateral surfaces take a more important part than a mere increase of surface. And the lugs may be made slightly conical so that their bases cover practically the whole surface, while their thinner ends are far enough apart to permit the free circulation of the hot gases. When placed radially on the outside of the tubes of a water-tube boiler, they may be cylindrical yet have their cooler ends close together and their hot ends farther apart.

Many comparative tests in which the time was noted for evaporating the same quantity of water over identical flames and in identical open cups, differing only in the size, number and shape of the lugs, showed that there were some best proportions at which the heat flow was greatest, as varying the proportions in either direction gave less good results. These tests also showed very decidedly that the view generally held that a gain by the use of lugs was due to the increase of surface is entirely wrong, which no doubt explains why the frequently suggested addition of lugs and similar surface-increasing devices has not come into general use; the principle was not the correct one. It is of course true that a greater heat-receiving surface is a good feature, but it will amount to little or no gain in the rate unless the thermal resistance of the lugs is properly proportioned. In one test the lugs were made of the same length and total cross-section, but had greatly differing surfaces by making one set very flat and the others round; those having the lesser surface actually gave decidedly the better results. The results in many tests were absolutely out of proportion to the surfaces, showing how greatly in error our former views were.

The desired condition is to have such a thermal resistance that when the flow of heat through it has become steady, the hot ends will be maintained at such a high temperature that the film resistance is greatly reduced. With the same resistance the difference of temperature at the two ends will therefore also depend on the flow of heat through it, as a large flow of heat through a low resistance may produce the same difference of temperature between the ends as a small flow through a high resistance; it is quite parallel to the electrical analogy. The proportions, moreover, are different for iron and for copper lugs. It is therefore not only a question of the resistance alone, but also of the resulting flow of heat; the problem of finding the best proportions is therefore not as simple as might at first appear, and the conclusions drawn from experiments must be carefully interpreted or they may mislead.

For instance, a thin coating of enamel or of some asbestos compound might be used as the artificial thermal resistance, but owing to its high specific resistance a very small heat flow through it would suffice to raise the temperature of the outside high enough to break down the film resistance; but as it is a large heat flow that is wanted, the artificial resistance should be made of as good a conductor as possible in order that it may require as large a flow of heat as possible to bring about this film-breaking temperature; the larger this heat flow, the lower need this artificial resistance be.

RESULTS OF TESTS BY OTHERS

During the earlier stages of the writer's researches some disinterested parties conducted some carefully made tests in which water was heated by the gas flames of ordinary cooking stoves in open vessels with various kinds of lugs, the amount of gas and its calorific value being determined; their best results were that the same quantity of water could thus be heated about twice as fast with about half the gas; since then the writer has obtained considerably better results.

Referring to Fig. 2, with lugs of the same diameter and of different lengths, as 2, 3 and 4, regularly spaced, the relative flows of heat through a lug were approximately those indicated by the vertical lines above them, that for 1 being the flow through an equal area of the bottom without any lug, therefore representing the normal practice of today. It will be noticed that for the greatest length, 4, the flow again became less. showing that the best length had been exceeded.

In Fig. 3 the lengths of all the lugs are the same, but their diameters are diminished. The vertical lines in this case represent the relative heat flows per unit cross-section of the lugs; lug 4 was the same as 3 in Fig. 2. Here again the last one, 6, showed that the best proportions had been passed.

In ordinary boiler practice the normal heat flow is generally given as three pounds evaporated per square foot of heating surface per hour, though this is sometimes exceeded, being said to be as high as 16 in some locomotive boilers, though probably at a considerable sacrifice of thermal efficiency.

The writer's researches were made in open, flat-bottomed tin cups, each having on its bottom a set of regularly spaced equal lugs, the proportions of the lugs being different for each cup, the one without any lugs being taken as the zero of reference. The same quantity of water was evaporated in each, with the same large though quiet bunsen flame, and the time was noted. Reduced to pounds per square foot per hour, some of the many results were as follows:

In the cup without lugs the heat flow corresponded to the evaporaton of about 17 lb. per sq.ft. per hour. This and not three pounds should be taken as the basis of the comparison with the lugs.

This rate being allowed for the portion of the bottom which is between the lugs, the rate through the lugs themselves was as high as 467 lb. per sq.ft. per hour, showing how the heat rushes through the thermal openings in this film made by the lugs when they are properly proportioned; this rate is about 27 times that for the cup without lugs, hence surprisingly great; the spheroidal state, which limits this rate, was not yet reached. The film resistance had then been reduced in effect to about two per cent. of what it was originally.

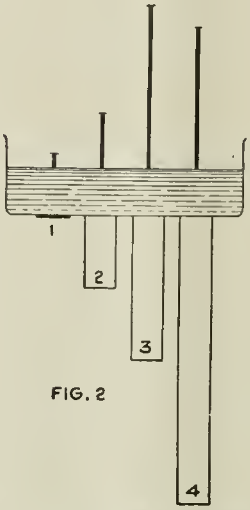

FIG. 2

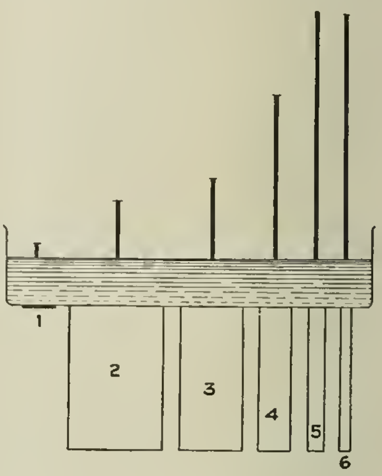

FIG. 3

FIG. 2. SAME DIAMETER AND DIFFERENT LENGTHS.
FIG. 3. SAME LENGTHS AND DIFFERENT DIAMETERS: FLOW PER SQUARE INCH SECTION

This shows how very much greater the heat flow through the properly proportioned lugs is as compared with the flow through an equal surface without lugs, and therefore how very greatly the resistance of this film in ordinary practice cuts down the transference of the heat to the water. In that particular test the lugs were spaced rather far apart, in order to find out what might be expected per lug when the hot gases have free circulation around them, and it is therefore of interest only in showing the possibilities and the correctness of the principle. This extremely high rate might perhaps be approached, say half way, in practice in the case of small-diameter boiler tubes in which the cooler ends of the lugs are as close together as possible and the hot ends far apart; but these lugs were rather too slender and numerous for practical purposes, except perhaps for very small boilers or water heaters.

With the same size lugs but spaced much closer together, thus getting less flow of heat per lug but more per square inch of total surface of the whole bottom, the result was about 60 lb. per sq.ft. per hour for the total bottom of the cup, which is still about 3½ times as great as for the cup without lugs.

These lugs were perhaps too slender and numerous for large boilers in regular practice, though perhaps not so for cooking utensils. Making the lugs four times as large in cross-section and using less than a third as many, the result was about 55 lb., hence only slightly less and still about 3¼ times that for the ordinary surface.

These results, surprising as they are, could no doubt be still further improved by further researches in this direction. There are other factors which also increase the heat flow, such as ending the lugs in points or edges, making them conical, etc.; moreover, heat seems to flow more readily from copper to iron than the reverse or than from iron to iron, hence copper lugs on iron vessels may give improved results; a moderate blast against the lugs also seems to have a greater effect than against a plane surface.

But even if in boiler practice and for cooking utensils, hot-water heaters, etc., the present rate could be only doubled, it would still mean that the same size of boiler would generate steam twice as fast and probably with even a slight gain in heat efficiency, and for household cooking utensils used with gas stoves it would mean heating twice as fast with half the gas. The bottom of the cooking utensils can be cast with the lugs, and in steam boilers the lugs can be electrically welded to the tubes, hence neither involve anything impracticable or costly.

Nugent Gravity Filter for Large Plants

In designing this oil filter accessibility and efficiency were the leading aims. Any part of the filter may be opened quickly for inspection, cleaning or repairs. The principle of operation is the same as that of the circular filter described in the Mar. 30, 1915, issue of *Power*. The new filter, which is square in section, is for large work, and can be made in capacities to filter 100 gal. per hour up to any size required.

Oil to be filtered enters through the inlet *A*, or it may be poured in by hand by lifting the lid to the screen chamber *K*. The oil flows through the special filtering material located between two vertical screens *R* in the top chamber and down through the pipes *L* into the settling and water-separating chamber. The latter is fitted with a steam-heating coil *G*, which runs around all four sides, also with lids to provide for inspection and cleaning while filtering is in process.

From this chamber the water flows up through a baffle box *O* and finally out through the discharge pipe *E*, as indicated by the arrows. This pipe is fitted with the observation fixture shown in either view. The oil rises in the settling chamber and overflows into the pipe *N*, passing down to the distributing header *P*, from which it is fed through stop-cocks to the filter bags. The header has caps at each end outside the filter, their removal facilitating inspection or cleaning.

The filter bags are oval in shape and are hung side by side on racks. Any set may be lifted out through the front door without disturbing the others. The bags are made of special filtering cloth. They cannot touch each other when full, nor can the contents overflow into the clean oil below, any excess being discharged into the outside troughs. Incandescent lamps placed at *H* illuminate the bag chamber.

The clean oil is drawn off at *B*, dirty oil and water at *C* and the clean oil overflows at *D*. Outlet *F* drains the settling chamber when repairs are necessary. The capacity of the filter shown is 500 gal. per hour, but, as previously stated, any size can be furnished from 100 gal. per hour up. William W. Nugent & Co., Chicago, Ill., are the makers.

Power Plant Burns Locomotive Cinders

The new power house of the large railroad station that has just been completed at Frankfort on the Main, Germany, despite the difficulties due to the scarcity of labor and material, is the first large railroad power station in the world to be operated entirely on the cinders taken from the locomotive. These cinders, according to the *Frankfurter Zeitung*, are piled in heaps from which an electric traveling crane runs directly to the boiler room.

Three boilers of 250 sq.m. (2691 sq.ft.) heating surface are fired by automatic underfeed stokers. Cinders alone or mixed with coal dust are used with a value of about 13,800 B.t.u. The steam is used to drive two turbines of 2000 hp. each, which generate current for the entire lighting and power equipment of the station. The foundation for a third turbine of the same capacity has been put in for future expansion.

FRONT AND END VIEW OF GRAVITY FILTER FOR LARGE POWER PLANTS

The Electrical Study Course—Elementary Single-Coil Dynamo

It is shown in this lesson how, when a coil of wire is revolved between the poles of a magnet, it has an alternating electromotive force induced in it and how this alternating voltage may be changed into a direct potential in the external circuit by means of a divided ring.

THE windings on the armature of a generator consist of a series of loops or coils grouped in various ways, depending upon the type of machine, voltage, etc. The simplest form would be one loop arranged to revolve between the north and the south pole of the magnet, as shown in Fig. 1. The ends of the loop connect to the rings R_1 and R_2, with brushes B_1 and B_2, resting on the latter to form a rubbing contact between the revolving loop and the stationary external circuit C. Considering the loop to revolve in a clockwise direction, as indicated by the curved arrow, the side of the loop under the N pole will be moving downward while the side under the S pole will be moving upward. The lines of force are from the N to the S pole; therefore, by applying the rule for the direction of the electromotive force generated in a conductor cutting lines of force, it will be found to be as given by the arrows on the two sides of the loop, which is away from the reader under the N pole and toward the reader under the S pole. This is just as it should be, since the lines of force are in the same direction under each pole, but the direction of the conductor under one pole is opposite to that under the other.

Factors Governing Value of the Voltage

By tracing around through the loop it will be seen that the e.m.f. generated in the side under one pole is added to that under the other pole. Or, in other words, we have the same condition as when two voltaic cells are connected in series, and if two volts are generated in one conductor, the two conductors in series will generate four volts. Hence, it is seen that one of the factors which govern the voltage of a given generator would be the number of conductors connected in series. For example, if instead of only one turn in the coil, as in Fig. 1, we have two turns in series, as in Fig. 2, and if the coil is revolved at the same rate and the magnetic density the same in both cases, then each conductor under a pole will have equal voltage generated in it. Again, by tracing through the coil, it will be seen that four conductors are in series; consequently, the voltage generated in the coil will be four times that in one conductor, or in other words the voltage increases as the number of turns in the coil is increased.

Another way to increase the voltage would be to increase the speed of the coil; that is, if the number of revolutions per minute made by the coil was doubled, the number of lines of force cut by each conductor would be doubled. Consequently, the voltage would be increased by two. A third way that the voltage generated in the coil may be varied is by changing the number of lines of force in the magnetic field. If the speed of the coil remains constant, but the strength of the magnetic field is doubled, then double the number of lines of force will be cut in a given time. The latter is the one way usually employed for varying the voltage of all modern generators and will be treated in a future lesson.

Current Reverses in External Circuit

In Fig. 1 the flow of the current is from conductor a to ring R_2 and brush B_2 through the external circuit C and back to brush B_1 and ring R_1 and back into conductor b, thus completing the circuit. When the coil has made one-half revolution, as shown in Fig. 3, conductor a will be under the N pole and conductor b under the S pole, as shown, with the result that the direction of the voltage generated in the two conductors is reversed. The direction of the e.m.f. in conductor a, Fig. 1, is toward the reader, but in Fig. 3 it is away; in b, Fig. 1, the direction is away from, while in Fig. 3 it is toward the reader. The result of this change in direction of the voltage in the coil is a change in direction of the current in the external circuit, as indicated by the arrowheads. From this it will be seen that on one-half of the revolution the current is flowing through the circuit in an opposite direction to that on the other half of the revolution; that is, the current is caused to flow back and forced through the circuit. If the voltage in the armature conductors change in direction as they pass alternate north and south poles there must be some position where the voltage is zero; this is indicated in Fig. 4.

When the coil is in the position shown in Fig. 4, it is moving parallel with the lines of force and is therefore not cutting them, and consequently not producing any voltage. From this point the voltage increases until the conductors are at the center of the polepieces, where they are moving at right angles to the lines of force and are therefore cutting the flux at a maximum rate, consequently producing a maximum pressure. For the next quarter of a revolution the voltage decreases to zero.

Electromotive Force or Current Curve

The series of values that the voltage or current passes through in the coil during one revolution may be expressed in the form of a curve, Fig. 7. The distance along the straight line between the two zero points of one curve represents the time required by the coil to pass the pole faces, or in Figs. 1 to 4, to make one-half revolution. The vertical distance between the line and the curve at any point represents the value of the voltage or current in the coil at that instance. The curve above the line represents current or voltage in one direction, while the curve below the line represents current or voltage in the opposite direction. A current or electromotive force that changes in direction in the circuit as shown in the foregoing is called an alternating current or electromotive force.

The voltage generated in the armature of all commercial types of generators is alternating, no matter whether the current in the external circuit flows in one direction or is alternating back and forth. If we want the current to flow in one direction in the external circuit, or, as it is usually called, a direct current or continuous current, some means must be provided to change the alternating voltage generated in the armature coil to one that is always in the same direction in the external circuit.

In Fig. 5 is shown a scheme that will maintain the voltage in one direction in the external circuit. Instead of the ends of the coils connecting to two rings, as in Figs. 1 to 4, they connect to the two halves of a divided ring. In the coil position shown, brush B_1 rest on segment S_1 and the current in the external circuit is in the direction indicated. When the coil has revolved a half-revolution as in Fig. 6, brush B_1 is resting on segment S_2, and although the current has reversed in the coil from that in Fig. 5, it is maintained in the same direction in the external circuit, as indicated by the arrowheads.

Although the voltage is applied in one direction to the external circuit, the current will not be of a constant value on account of the varying value of the voltage. What will be obtained is a current that flows in waves, as shown in Fig. 8 and is known as a pulsating current. To obtain a constant current for a given value of resistance in the external circuit, or, as it is usually called, a direct current, it is necessary to have a number of coils on the armature and the ring divided into as many sections as there are coils. This will form the subject of a future lesson.

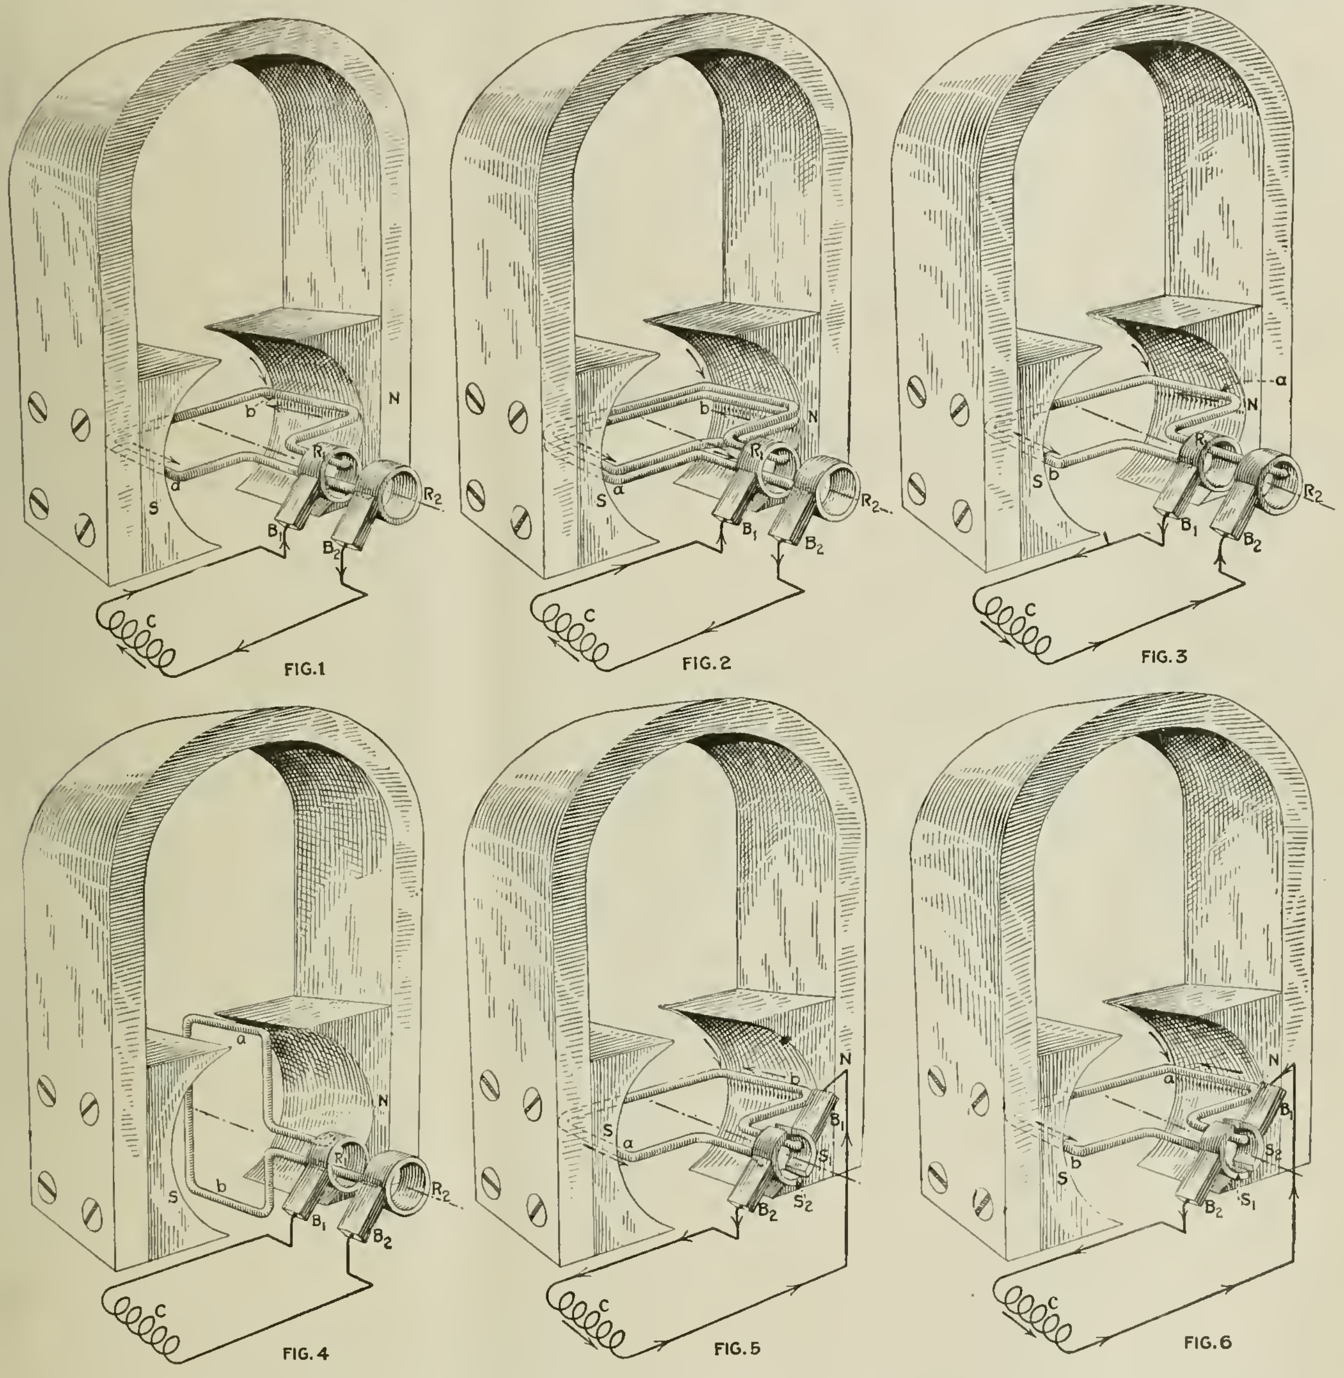

FIG. 1 FIG. 2 FIG. 3 FIG. 4 FIG. 5 FIG. 6

FIGS. 1 TO 6. ELEMENTARY ELECTRIC GENERATOR, CONSISTING OF ONE COIL AND HORSESHOE MAGNET

Fig. 9 shows the layout of the study problem given in the last lesson. The conductors from the source of power will have to be large enough to transmit a current $I = I_1 + I_2 = 150 + 125 = 275$ amperes. Referring to the wire table, it will be found that a 300,000-cir.mil, rubber-covered conductor is required for 275-amp. load. Between the first and second load, the conductors need only be large enough to take care of 125 amperes and according to the wire cable, a No. 0 wire may be used. The resistance of the circuit from the source of power to the first load is that of 700 ft. of 300,000-cir.mil conductor, which is $R = \frac{10.7L}{cir.mils} = \frac{10.7 \times 700}{300,000} = 0.025$ ohm. Volts drop in this part of the circuit is $E_d = RI = 0.025 \times 275 = 6.875$ volts, and the voltage available at this load is $E_a = E - E_d = 240 - 6.875 = 233.125$. The resistance R_1 of the circuit between the two loads is that of 550 ft. of No. 0 conductor, or $R_1 = \frac{10.7L}{cir.mils} = \frac{10.7 \times 550}{105,500} = 0.056$ ohm. Volts drop in this part of the circuit is $E'_d = R_1 I_2 = 0.056 \times 125 = 7$ volts, and the available voltage at the load is $E'_a = E_a - E'_d = 233.125 - 7 = 226.125$. The watts loss in the first section of the circuit is $W'_l = E_d I = 6.875 \times 275 = 1890.625$. In the second section the watts loss in the line is $W''_l = E'_d I_2 = 7 \times 125 = 875$, and the total watts loss $W_l = W'_l + W''_l = 1890.625 + 875 = 2765.625$. The watts supplied to the first load is $W'_a = E_a I_1 = 233.125 \times 150 = 34,968.750$, watts supplied to the second load is $W''_a = E'_a I_2 = 226.125 \times 125 = 28,265.625$, and the total watts supplied to the two loads is $W_a = W'_a + W''_a = 34,968.750 + 28,265.625 = 63,234.375$. The total watts supplied to the system is $W = W_l + W_a = 2765.625 + 63,234.375 = 66,000$. The total watts is also $W = EI = 240 \times 275 = 66,000$, which checks up with the foregoing value.

Taylor Condensation Meter

The desirable feature of a meter is accuracy and dependability for long periods of service. A meter that seems to possess these with other desirable characteristics has been designed by the Taylor Underground Heating System, Pittsburgh, Penn.

This meter (Fig. 3) contains, within a metal case, four copper and brass buckets (Fig. 1) attached to an anti-rust shaft which revolves in an anti-friction self-lubricating bearing. The turning movement of the buckets and the shaft is so sensitive that the addition of one-quarter ounce of water will move the full bucket when it is ready to dump. The buckets are held in the filling position by a locking device in the dial box of the meter until the proper amount of water has been delivered to the bucket being filled. Then the full bucket moves to the dumping position; the next bucket cuts in when the full bucket moves $\frac{3}{16}$ inch.

The locking device is shown in Fig. 2. Each bucket is provided with a cam, the surface of which gradually increases in radius in the direction of the rotation of the buckets and terminates at its highest end in a stop projection *A*, the outer edge of which projects beyond the peripheral surface of the cam portion. A camwheel *B* revolves on a pin in the arm *C* and runs on the surface of the camwheel. This arm is fulcrumed at *D*, and the other end of the arm engages, by means of a slot, with the pin *E*, which is carried by the cylinder *F*, which telescopes over a plunger *G* pivoted to the metal case.

The dashpot plunger is made with an air-inlet port *I*, which is controlled by a check valve *J*. An escapement port *K* is provided, the lower portion of which is designed to be moved into and out of register with the opening *L*.

The operation is as follows: Water of condensation enters the meter at one end of the storage chamber, where it strikes a baffle plate. From the storage chamber the liquid flows through an opening (Fig. 1) and is deflected by the curved bottom of the vertical bucket into the bucket to be filled, which is held in its filling position by the engagement of the roller *B* (Fig. 2) with the stop *A*. When the bucket becomes filled with a predetermined weight of liquid, which is regulated by the adjustment of the weight *O*, the resistance of the roller against the stop is overcome and the shaft and the bucket will revolve one-quarter turn, until the next bucket is in the filling position and the full bucket is discharging. It is evident that as soon as the full bucket begins to rotate, the following one ceases to divert the liquid into it, and the empty bucket will be brought into position to receive the discharge from the receiving chamber.

After the roller passes over this stop to the position shown at the right of Fig. 2, the shaft revolves through 90 deg. to bring the next bucket into the filling position. In this position the dashpot cylinder has been pulled upward so that the ports *K* and *L* are out of register. During the next 90-deg. movement of the shaft the cylinder will be moved downward as the roller rides up on the cam. When the roller reaches the position shown at the left of Fig. 2, the arm has moved downward until the slot in the end engages the pin *E*, when the cylinder *F* is forced down a short distance, quickly compressing the air until the roller is brought to a rest by engaging one of the stops.

The purpose of the dashpot is to act as a controlling device so that the meter will not trip until the predetermined weight of liquid has been collected in each bucket. It also guards against possible spinning of the bucket shaft after it has been released and insures the stopping of the next bucket at the correct filling position. The air that is trapped in the dashpot cylinder acts as a brake upon the camwheel until such time as the cylinder moves to a position to bring the ports *K* and *L* into register.

As the buckets and shaft make a complete revolution, there is no possibility of the shaft wearing flat, and the turning movement also eliminates the deposits of sediment in the bucket.

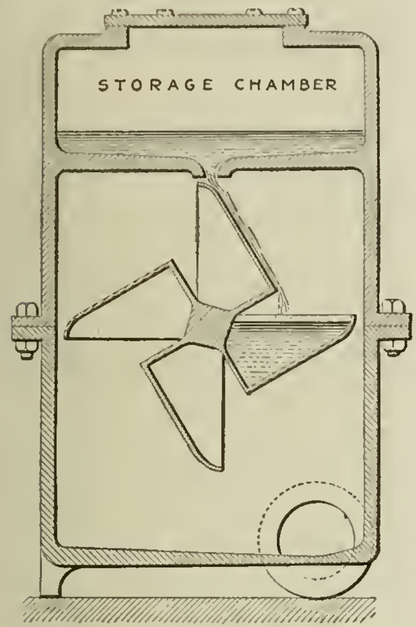

FIG. 1

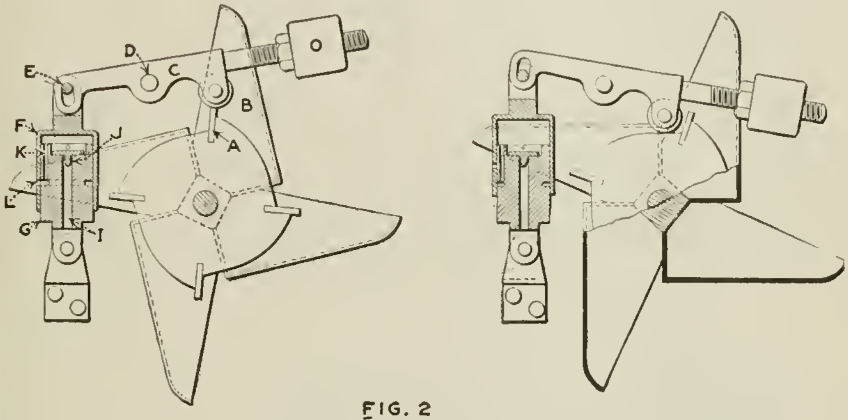

FIG. 2

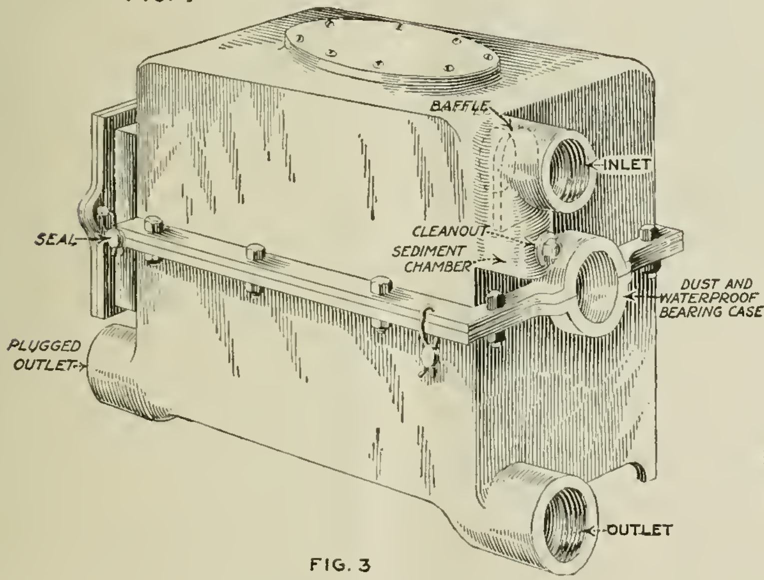

FIG. 3

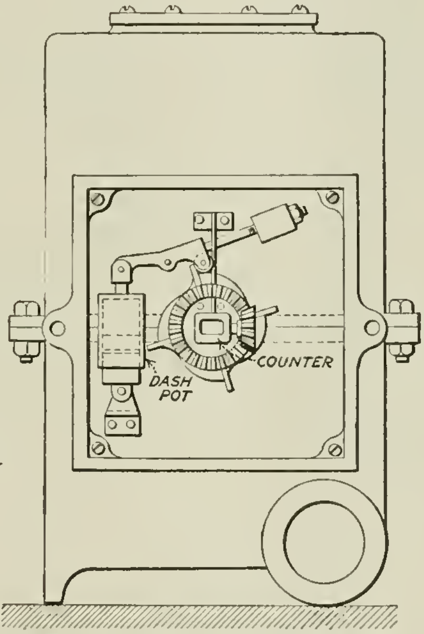

FIG. 4

FIGS. 1 TO 4. DETAILS OF THE TAYLOR CONDENSATION METER

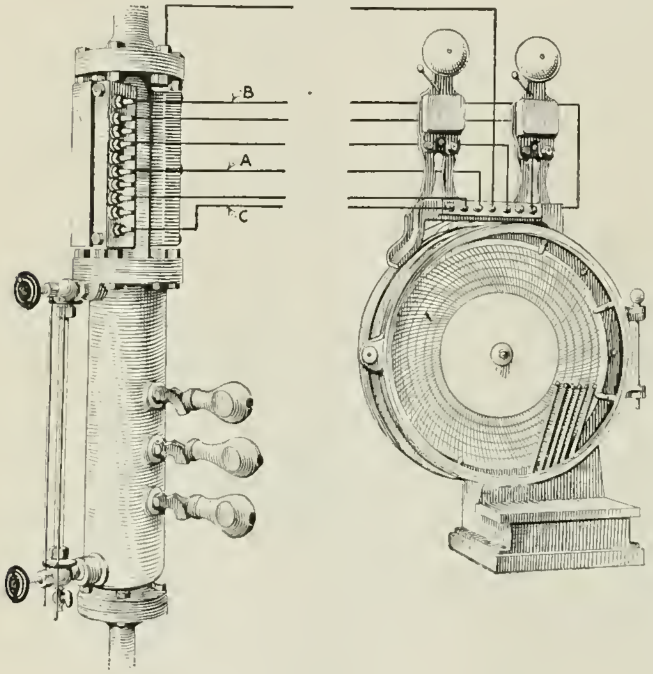
Fig. 1—Position of buckets when filling. Fig. 2—Details of locking device. Fig. 3—Meter box and connections. Fig. 4—Meter counting mechanism

All outlets are in the base of the meter, and therefore water will not remain in the bottom when the meter is not in operation. The count mechanism, Fig. 4, is inclosed in a damp- and dust-proof dial box to prevent corrosion. The meter reads direct; that is, if the dial shows 5000 it means that 5000 lb. of water has passed through the meter.

The meter is made in capacities from 400 lb. of liquid per hour to 200,000 lb. and is guaranteed to measure accurately to within one-half of one per cent.

Wight Electrical Boiler-Level Recorder

It is common to hear either the high- or the low-water alarm sounding in boiler plants. Water should not be allowed to drop too low because of the danger of burning the boiler, and when the water is carried too high there is the danger of priming and of slugs of water going over into the engine cylinder. Then there is the economic advantage in keeping the water level constant in that the feed water is put into the boiler only as fast as it is evaporated. Such regularity in pumping feed water also allows the maximum amount of heat transfer from the exhaust steam to the feed water in passing through the heater.



ELECTRIC WATER-LEVEL RECORDER

An instrument that has been designed to record the water level in a boiler, making a continuous record of extreme low, high and all intermediate levels, is manufactured by the Wight Electric Recorder Co., Cleveland, Ohio. This instrument consists of multi-recording pen arms and is equipped with both high- and low-level alarms. On the top of the water column is a contact chamber in which contact is made at the various terminals as the water level in the boiler changes. The contact mechanism is actuated by a noncollapsible float which is filled with gas, at approximately boiler pressure, which increases and decreases as the pressure on the outside of the float fluctuates.

The operation of the recorder is about as follows: Assume that the water level is at the middle gage of the water column, the float contact will make connection with the contact *A*, which is connected to a corresponding pen arm of the recorder. At extreme high-water contact is made with the connection *B* and with connection *C* at the low-water level; likewise with the remaining connections as the water may vary up or down. By this instrument a record of the water level carried during the 24-hour period covered by each chart is shown and at what time it was at any particular level.

The recording dial can be placed at any convenient point about the establishment, and the instrument can be used for a number of purposes, such as recording the trips of an elevator, skip hoist, mine skip or any other machine where a record of what it is doing is required.

Motor Sparked When Starting

By E. C. Parham

An armature coil that is short-circuited, as, for example, by two of the commutator bars being metallically bridged, will soon be burned out, because the voltage of the coil when in an active part of the field is considerable, while the resistance of the short-circuit is almost negligible. An armature coil that is open-circuited as, for example, by a broken or burned-off lead, will cause a spark to travel around with the commutator, the spark being maintained across the bars that include the open-circuit. Short-circuited coils are of comparatively frequent occurrence and so are open-circuited coils, but probably it is rarely that both conditions occur in the same coil, as they did in the following instance:

In regard to a 15-hp. 500-volt direct-current motor which was sparking, an inspector was informed that for more than a year the motor had been acting just as it was then. The commutator would show a traveling spark when the motor was being started, but as soon as the armature reached about half-speed, the sparking would cease. Inspection disclosed that one coil of the armature was entirely burned out as far as the course of the coil could be followed. Since the machine was taking only about one-third full-load current, and it was apparent that the motor would continue to run for some time as it had been running, and as it was essential that the machine be kept in operation, a new armature was ordered and the old one kept in service in the meantime.

When the new armature was installed, it was found that in the old one the ends of the affected coil were connected to adjacent commutator bars, the leads of which in some way became crossed, first short-circuiting the coil, then open-circuiting it. The open-circuit occurred in such a way that the two stubs that led to the commutator were apart as long as the armature remained at rest or did not exceed a certain speed. Above this speed, however, the stubs were forced against each other by centrifugal force, thereby bridging the bars that included the break and thus eliminating the traveling spark. A loose connection in the commutator frequently produces the foregoing effect.

Editorials

A National Engineers' License Law

A FEDERAL law providing for the examination and licensing of power-plant engineers in the same way that marine engineers are examined and licensed by the United States Board of Supervising Inspectors of Steam Vessels has been regarded as an impossibility under our Constitution upon the ground that it would be an unwarranted interference by the central Government with the internal affairs of the forty-odd sovereignties of which the Union is composed. So long as the preservation of the public safety was the only ground for such legislation, this contention was unanswerable, and it has been generally conceded that, in spite of the desirability of nation-wide and uniform requirements and practice, any regulation of this kind must be undertaken by the individual states.

But in these days when a common danger has emphasized the significance of common interests and the importance of general, over-all, inclusive efficiency, it is becoming apparent that there is a broader ground for inquiring into the operation of power plants in the communal interest. The immediately apparent motive for legislation against the use of unsafe boilers or the unsafe use of any boiler is the avoidance of killing and maiming people and destroying property in the immediate neighborhood. But the effect of a boiler explosion reaches much farther than this. In its reduction of man power, its interruption of production, its destruction of the fruits of labor, its addition to the burden of the community in caring for the injured and their dependents, it adds indirectly and in devious ways to the common cost of living. It is a defeat, a setback in the eternal conflict of man against the forces of nature; an impairment of his fighting force, a disaster with much more than a local significance.

The loss to the community, to the nation, from an occasional boiler explosion, considerable and desirable of prevention as it is, is insignificant as compared with the avoidable waste that is continually going on. Every ton of coal wastefully burned is an unnecessary impairment of the national resources and makes every other ton of coal and every unit of the product which it is burned to manufacture cost more.

The coal burned in the power plant of a shoe factory is an item in the cost of the product. If the product is sold at cost plus a fair profit, every purchaser of shoes has a monetary interest in the efficiency of the shoe manufacturer's power plant. In a time like this, when a shortage in the national coal bin is of such far-reaching, obvious and vital importance, the right of the nation to insist upon the economical use of fuel is practically unquestioned. Sixty-seven per cent. of the coal mined in this country is shoveled under boilers by about a quarter of a million firemen. It is claimed by those who have made a specialty of the subject that twenty-five per cent. of this could be saved by the exercise of a reasonable amount of care and an easily attainable amount of skill on the part of this quarter of a million men. Is it not conceivable that the people of the country in their collective capacity—that is, through the Federal Government—may insist that the steam plants of the country be operated efficiently as well as safely; and inasmuch as the effects involved are not confined by political boundaries but are nation-wide, that the supervision necessary to bring this about is a legitimate function of the Federal Government?

Save Coal in the Home

OF THE six hundred million tons of coal produced last year in this country, twenty per cent. was used for domestic purposes, and about fifteen million people shoveled this coal into their respective furnaces or stoves. The ordinary scoop shovel will hold about ten pounds of coal. At the prevailing market prices the small consumer had to pay five cents per shovelful for anthracite and for the same sum obtained double this amount of bituminous coal.

Such a small saving as one shovelful per day by each user would amount to seventy-five thousand tons, which for six months of the heating season, one hundred eighty days, increases to thirteen and one-half million tons.

The saving by each consumer is infinitesimal when compared to the total coal mined, but the aggregate saving is large. It is entirely possible to effect. More careful firing methods and overhauling of the furnaces to put them in first-class condition would do it. This particular case is only one of the many illustrations of what may be done when efficiency is the keynote and waste a crime. Under the circumstances it is the duty of every householder to reduce his coal requirements. One shovelful per day will work no hardship. It is a service that Uncle Sam will appreciate.

A New Principle in the Flow of Heat

IN AN article entitled "A New Method of Increasing the Evaporation in Boilers," on page 10, Dr. Carl Hering describes what might really be called a new principle in the flow of heat. The value of the legs of a pot as heating surface is one of the perennial subjects of discussion, and the use of knobs, projections and fins for increasing the absorption and radiation of heat is common, but Dr. Hering shows for the first time, to our knowledge, the underlying principle upon which such extensions should apparently be based, and by which their effectiveness may be greatly increased. When a flame plays against a relatively much cooler body, as that of an alcohol lamp against a beaker of water, there is formed a film of extinguished gas between the flame and the beaker, which cannot get away before it gets so cool that it will not char paper. The common experiment of sticking a postage stamp to the bottom of a tin dipper and boiling water in it without charring the stamp is a demonstration of this fact.

The author of the article in question found that the resistance of this film to the passage of heat diminishes rapidly with the difference in temperature between its confining surfaces; that is, between the hot surface of the beaker on one side of this film and the flame on the other side of it. The temperature of the flame is fixed, but that of the receiving surface can be increased by interposing a certain amount of thermal resistance between it and the relatively cool fluid. This, in effect, is what he says the "pot legs" should be made to do, and when they are proportioned in accordance with the principle described and the values obtained by Dr. Hering, they seem to add in a remarkable degree to the activity of the heat transfer. He maintains that his researches also show the older idea of increased surface to be false and misleading, which, if true, would show why others had been groping in the dark with but small gains.

Lightless Nights and Nonessentials

THE original Fuel Administration order on the dimming of electric signs, which was intended to restrict the use of fuel-consuming signs to the period between 7:45 a.m. and 11 p.m., has failed in producing the coal-saving results that were expected. There may be two reasons for this—that the users of the electric signs deliberately ignored the order regarding their use or that they continued to use them with the belief that no one else would obey the order and that the coal situation was not so serious as has been claimed.

It would seem that anyone at all interested in the fuel question would have come to the conclusion long before this that there is a fuel shortage, regardless of whether it is the fault of the mine producers or that of transportation. With factories shutting down in Pittsburgh, Cleveland and other cities because of a lack of coal sufficient to generate steam for power purposes, the fact of a coal shortage is being brought home in a manner that cannot be gainsaid, and coal users are beginning to realize that the coal question is a serious one throughout the country.

As a result of the noncompliance with the original order of the Fuel Administration, a new order has been issued and was put into effect on Sunday night, December sixteenth, when Broadway and other "white ways" throughout the country were made lightless. Under the new order two nights each week will be lightless nights, and these are designated as Sunday and Thursday. Under the new order the "white ways" of our cities are to disappear absolutely on the nights designated. The burning of lights contrary to the wording and spirit of the order will constitute a violation of the law, and steps will be taken by the Fuel Administration to mete out punishment to offenders.

The coal shortage has caused considerable unrest among the manufacturers of nonessentials, and perhaps the first city to bear the burden of the power shortage is Pittsburgh, under an order issued by Robert J. Bulkley on the authority of the Priorities Board.

Mr. Bulkley investigated the industries of Pittsburgh using electric power, and the new order as arranged will go into effect as soon as it is possible to get instructions from Washington designating the concerns that are making nonessentials, a list of which has already been compiled. The procedure, it is understood, will be merely to forward this list to the power companies and depend upon them to cut out electricity from these concerns, but the list may be revised from time to time. Munition plants will be given every privilege, and no further curtailment of their operation will be permitted.

To just what extent this measure of conserving coal for the necessary industries engaged in munition work will operate, cannot be foretold, and it is doubtful if the Government will favor arbitrary limitation of any industries except as a last resort, in the event of an acute shortage of coal. It stands to reason that when for any reason the coal situation in the country gets to a point where war interests are threatened with closing down, the nonessential producer will be obliged to suspend operations.

Business Editors at Washington

THE business press of the country talks to a large constituency in the language that its readers best understand and from the vantage point of an exponent of their interests. The esteem in which it is held by those in authority is evidenced by the fact that such people as F. W. Taussig, Chairman U. S. Tariff Board; Eliot Wadsworth, Vice Chairman American Red Cross; J. D. A. Morrow, Secretary National Coal Association; Harry A. Garfield, Fuel Administrator; Food Administrator M. L. Requa; Frederic A. Delano, Member Federal Reserve Board; Senator Francis G. Newlands, Chairman Joint Congressional Committee on Interstate Commerce; E. N. Hurley, Chairman of Shipping Board; Senator Atlee Pomerene, Member of Committees on Banking and Currency, Foreign Relations, and Manufactures; Dan C. Roper, Commissioner in Charge of Collection of Excess Profits; A. W. Shaw, Chairman Commercial Economy Committee, Council of National Defense; Dr. Anna Howard Shaw, Chairman Woman's Committee, Council of National Defense; and C. A. Richards, Chief Bureau of Exports, agreed to meet a delegation of some seventy-five editors of American business papers and give them in short addresses the high points in the work which they are doing. J. D. A. Morrow, Secretary of the National Coal Association, appeared in the place left vacant upon the program by the failure of Secretary Lane to appear, and M. L. Requa represented Mr. Hoover, who was unable to be present. Dr. Garfield's remarks on the coal situation will be found in another column.

President Wilson's taking over of the railroads will be generally approved. The transportation system of the country should be an entity operated at maximum efficiency, not as measured by the ratio of dividends to investment but by the ratio of service to cost. It may be that somebody's remark about unscrambling eggs may come home to roost.

The index to Volume 46 (the last six months of 1917) will be ready shortly and will be sent to all whose names are on the index mailing list. Any others who wish will be put on the list. A post-card request is sufficient.

Correspondence

High Speed of Steam Turbines

In connection with the question of steam-turbine failures, which is discussed in recent issues of *Power*, a statement of our practice and experience might be of interest to your readers.

The safe speed for our standard noncondensing wheel is so far in excess of the usual operating speed that we do not as a regular practice find it necessary to run any special overspeed test unless the turbine is to operate regularly at an unusually high velocity. The regular overspeed run which we make for the Government is 25 per cent. over the normal rating. The maximum test speed at which we can operate our different rotors is so far above this value, however, that we seldom approach it. These maximum test speeds vary from 4000 to 7000 r.p.m., depending on the diameter of the wheel.

When it is considered that for condenser-auxiliary drive, boiler-feed or boiler-draft service operating speeds for direct-connected units seldom exceed 2500 r.p.m. and for 60-cycle alternator speeds, 3600 r.p.m., such high-test speeds allow a wide margin of safety.

It is possible to injure any wheel by sufficiently overspeeding it, and it is highly important that the design of a wheel be such that if it is accidentally run to this speed as little damage as possible will result. To insure maximum strength, the Terry rotor is cut from solid steel, even the buckets being milled from the solid steel. The semicircular notch in the center of the bucket incidental to manufacturing proves a further source of strength and safety, due to a reduction in blade weight and stresses. When the speed is approaching the danger point, the corners of the bucket next to the semicircular slot begin to bend upward. These will strike on the edges of the reversing chambers and will usually give warning before anything very serious occurs. The web is made much stronger than the blades, so that should the turbine overspeed for any reason whatsoever, the individual blades would shear out, resulting in decreased speed before reaching the danger point for the web. The blades are very light, therefore the worst they can do is to injure the nozzles and reversing chambers. We have actually run machines to destruction for experimental purposes, and found that when this occurs no part of the turbine rotor will come through the casing. Although we have more than 4000 turbines running, we know of only one case in which anyone has been injured by a wheel bursting and that by a type we no longer build.

Some time ago, while making tests on our multi-stage condensing machines, we took a wheel which was then standard and ran it to destruction. The blades were one-third longer than any blade of equal shape we are now using. The wheel disk, was, however, of the same type as now used. At approximately 5200 r.p.m. the buckets came out of their fastening. Since that time improvements in the strength of our blade fastening have made it three times as strong as at the time of the test. We are using no blades as heavy as the ones that were in the first wheel and are limiting the speeds on this particular diameter of wheel to 4000 r.p.m. in the multi-stage machine. As constructed now, these wheels will safely stand a test speed of approximately 6000 revolutions per minute.

In addition to having a high factor of safety for the wheel, in the standard noncondensing turbine there are no close side clearances to be maintained and there can be no fouling of the blades due to a slight axial wear or misadjustment. Even if the bearings wear down, the moving blades cannot strike on the stationary blades, as they are protected by a substantial rim that projects beyond the blade. The only thing that can strip the blades is serious overspeeding or the presence of some foreign substance.

Suggested Designs for Centrifugal Machinery

I was interested in reading C. E. Pratt's letter on "Suggested Designs for Centrifugal Machinery" and his comments on the steam motor in the Nov. 20 issue of *Power*, page 704.

Mr. Pratt suggests going a step farther with the design than suggested by the Steam Motors Co., by doing away with the bedplate and having the pump and turbine bolted together by vertical flanges. This design is quite feasible and has been already adopted by one or two manufacturers. But when we attempt to make a rabbeted fit at this point, it must be borne in mind that this is not so easy as it looks for the reason that these two flanges will be machined in separate shops, which is a different proposition to machining both flanges to one set of gages.

Again, this arrangement necessitates a special pump, whereas with the design suggested in the steam motor a standard pump is used without any change in existing patterns.

I do not quite understand Mr. Pratt's reference to a third bearing, in the second paragraph of his letter. He asks: "Why not do away with the third bearing, leaving in this instance the prime mover entirely overhung?" This is exactly the way the steam motor is designed, and there are only two bearings in the steam motor combination, as he will note if he looks over the original article.

Regarding the question raised by Mr. Pratt as to why more manufacturers do not build both ends of the unit, the answer is that this is an age of specialization and a concern which devotes all its energies to manufacturing one particular line of apparatus is in a better position to perfect that than if it built several different lines. Mr. Pratt goes on to say that this would, in most cases, solve the problem of assembling two machines, in addition to having only two bearings for the complete unit. As already mentioned, this is what we have with the design of the steam motor. We do not assemble two machines together in the true sense of the word, as the steam motor automatically becomes part of the equipment to which it is attached and has the advantage, which Mr. Pratt feels is very important, of having only two bearings for the complete outfit.

I am entirely in sympathy with Mr. Pratt's ideas regarding standardization, and he will find a paper devoted in a great measure to this subject, presented before the American Society of Mechanical Engineers at its annual meeting in December, 1917. [This paper will soon appear in *Power*.—Editor.]

American Blowing Engine in Italy

One of the remarkable events taking place in Italy today is the supplanting of German machinery by American products. The war is teaching Italy that an exchange of her surplus products for American goods is preferable to the pre-war dumping system.

Throughout the country one meets American engineers assembling or erecting American machinery. In Turin over one hundred Baldwin locomotives have been delivered recently, and in Brindisi more locomotives are being assembled, and the chain is complete from the Alps to the southern Adriatic. An American engineer, Henry Louis Hammerle, is erecting for the Mesta Machine Co., of Pittsburgh, a monster blowing engine at the Ilva steel works in Bagnoli, near Naples. This blower, the largest in Italy, is designed to deliver 37,100 cu.ft. of air per min. to the blast furnaces where Elba Island iron ore is reduced. The bedplate alone weighs 160,000 lb. and is larger than any other casting ever imported into or manufactured in Italy. It was with much difficulty that the engine was stowed for shipment aboard a tramp steamer, and it was then buried under a load of coal. Its total weight, including the flywheel, is 1,200,000 lb. The flywheel is 24 ft. in diameter and weighs 160,000 lb. The cylinder is 46 in. diameter and 60-in. stroke.

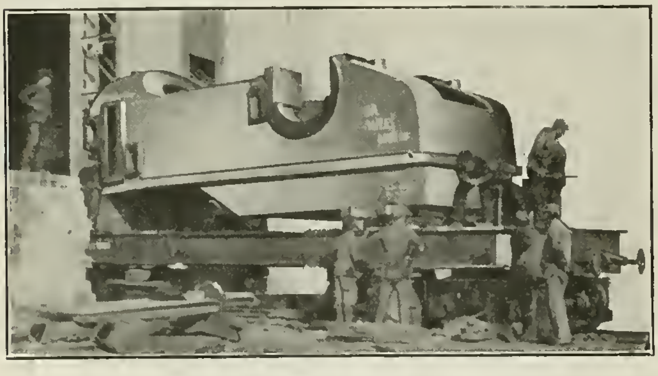

FIG. 1. UNLOADING THE ENGINE BEDPLATE AT THE PLANT

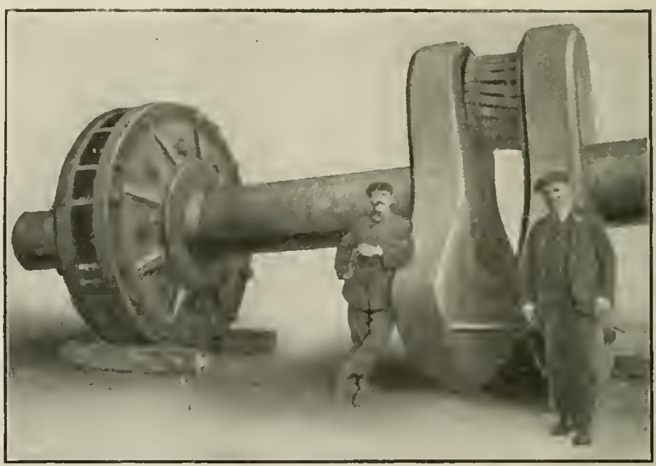
The Italian buyers are pleased with the complete oiling system of the engine, since it saves 75 per cent. of the oil, a matter of great importance in Italy. The foundations beneath their other engines are saturated with wasted oil. Italy produces no lubricating oil or coal, and very little iron, and Italian manufacturers are forced to look to other countries for these materials. Nearly all the oil and steel now come from the United States. One firm has used 300,000 tons of American steel since the war began, and another, a munitions plant, is using 2400 tons a month. About two- thirds of Italy's coal comes from England and the remainder from America. The present price of coal is one thousand lira ($130) per ton. American products find a welcome in Italy even under the present almost prohibitive freight rates.



CRANKSHAFT AND HUB OF FLYWHEEL

The illustrations show the bedplate and crankshaft of the blowing engine referred to in the foregoing.

Paris, France. A. R. Decker.

The Engineer and the Union

Referring to the letters that have recently appeared concerning the engineer and the union, I think the unions are good enough in their way, but are lacking in one important respect; namely, almost anyone can call himself an engineer and join the union. The unions should have an examination as strict as that of the license examiners, so that the employer can have no justification in objecting to the higher wages demanded, considering both the safety of his plant and his pocketbook. So many employers have been stung that one can hardly blame them for their objection to employing uncertified men.

But another unfortunate side of the question is, that with the present scale of wages there is not much encouragement for a young man to keep plugging for a higher position with the responsibilities and cares of the chief engineer. We can't all be bosses, so all we can do is to train for the position and be ready when the opportunity arrives. In the meantime we should have a wage sufficient to maintain ourselves, with a few of the good things of life on the side.

These are views I have heard expressed by engineers in different parts of the country. Something should be done, and the greater the publicity the subject can be given the better. I would like to see conditions changed, but it will probably take a long time.

Emmett, Idaho. George R. Dye.

Extension Oil-Can Spout

In the issue of Oct. 30, page 603, Mr. Forray shows an extension for an oil can for oiling parts above reach without climbing a ladder. A convenient way to oil parts below reach when no long-spout oil can is at hand is by attaching a stiff iron or copper wire to the spout of an ordinary oil can as shown in the illustration. As the oil comes out of the spout it will follow the wire to the point intended. D. R. **Hibbs.**

New York City.

Bad Packing Conditions Overcome

I experienced a lot of difficulty trying to hold the piston-rod packing in an engine under my charge. I cast two rings of babbitt to fit the rod closely and go into the stuffing-box. One of these was put in the bottom or back end of the stuffing-box, then soft packing and last the second ring of babbitt.

With the gland tightened up only moderately, the packing does not leak and the engine runs splendidly.

Altman, W. Va. **John French.**

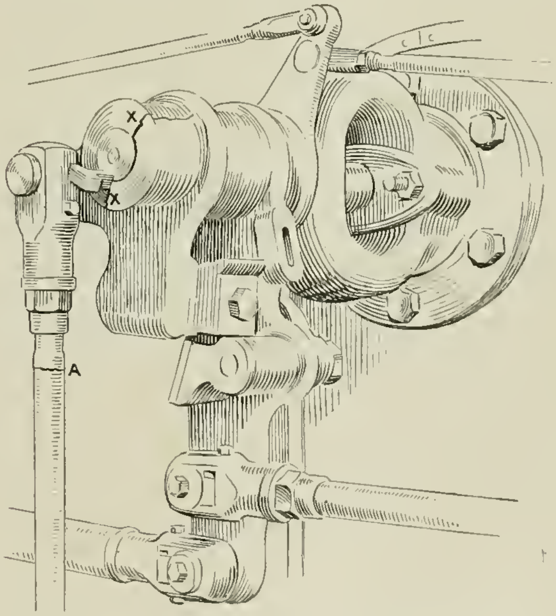
Valve Gear Broken by "Blocked" Valve

One unit of a large power plant is a 700-hp. simple Corliss engine. One noon hour, after most of the plant crew had finished lunch and were sprawled around the engine room waiting for the starting whistle, a blood-curdling racket, described as a cross between a cat serenade and a hog-killing squeal, started in a corner of the room. The lights danced and the brushes on the generator flashed and squealed; so the men "scooted" out by the shortest route through doors and windows and, after reaching what they considered a safe distance, turned to see if the whole power house was following.

The chief, one assistant and one oiler were the only ones who stood their ground, though in truth they were all shaky in the knees, and they began a cautious investigation to determine where the unearthly sounds originated. They seemed to come from the corner where the feed-water heater was located, and while they were gathered around the heater for a moment there was a howl at the commutator of the large engine unit running in parallel with two smaller ones, followed by several flashes, and the circuit-breaker "kicked" out. The chief shut off the throttle and noticed that the dashpot rod was broken at *A*, as shown in the illustration, and that the steam arm was gone—had dropped into the oil pan under the valve gear so that the bare valve stem was staring him in the face.

The steam arm had been broken across the hub, as indicated by *X* in the sketch. In attempting to turn the valve closed, it was found impossible to do so, but it moved freely in the reverse direction, and when the bonnet and valve were removed it was found that a piece of the threaded end of a pipe had dropped into the steam chest and worked into the port when the valve opened, and prevented it from closing, and of course something had to let go; in this case it was the steam arm.

The explanation of the noise was then simple, for the steam valve being wide open, every time the exhaust valve opened, the steam at full boiler pressure rushed into the exhaust line that ran under the floor as far as the heater, where a tee connected it with the vertical riser to the back-pressure valve. Evidently, considerable water had accumulated in this tee during the light load period at the lunch hour, so that when the live steam rushed through, it caused the terrific racket and the engine could work only on one end, so the governor was unable to control the speed and voltage and the circuit-breaker went out with the usual fireworks. A new dashpot rod was made and the broken steam arm was oxyacetylene welded and rebored, after which it served the purpose as well as ever. The repairs were made and the engine was ready to run in three hours after the accident. E. W. **Miller.**

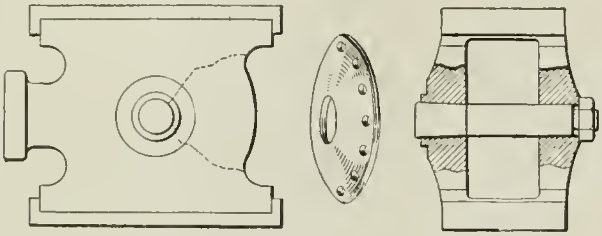


STEAM ARM AND DASHPOT ROD BROKEN

Minneapolis, Minn.

Repairing a Broken Crosshead

The wristpin of a Corliss engine (18 x 42) was worn, so we placed the crosshead in a wheel press to remove the pin, as it had been pressed in, but in doing so the crosshead was cracked as shown by the dotted lines in the illustration. The crosshead was clamped firmly, chucked in the lathe and the side turned off, leaving a half-inch boss, or shoulder, around the eye. Then a piece of ½-in. boiler plate was shaped, as shown, with the hole in the center a little smaller than the boss on the crosshead. After being heated in a forge, it was placed on the crosshead and hammered to a good fit. When cold, it had drawn the parts together so closely that the cracks could hardly be noticed. Holes were then drilled around the patch and tapped out for capscrews, making the job entirely secure.



FLANGE SHRUNK ON A BROKEN CROSSHEAD

Change of Water Supply for Air Pump

In answer to L. F. Forseille's request, page 703 of *Power*, Nov. 20, relative to changing injection piping to air pump, I offer the following: I take it that the increase of 75 deg. F. of the injection water referred to by Mr. Forseille is the range between the cold water of winter and the warmer water of the summer months.

In designing the air-pump runner the builder would figure on capacity with the warmest water it was to handle in operation, which would be in the summer, and as a drop in temperature in the colder seasons would increase the air-runner capacity, the manufacturer would not worry about that. When the air runner is handling water of a given temperature, it discharges it with a certain velocity, assuming the runner to have a fixed peripheral speed.

At this temperature, volume, weight and velocity the slugs of water exert a certain velocity head, which is transformed into pressure head in the diffusion nozzle upon leaving the runner and so overcomes the discharge head the runner works against.

Now, if we consider that the air runner is designed to discharge a certain amount of air in the summer months with water at 80 deg. F., and we increase the temperature to 110 or 115 deg., as the suggested increase would do, we necessarily increase the volume of the water for a given weight, and this lighter water by volume limits the ability of the runner to store enough kinetic energy in the slugs of water to overcome the forces acting against the water.

In concluding I would suggest increasing the pump speed, as a small increase in speed will probably secure the desired results. R. B. Goold.

Leadville, Colo.

Water Too Hot for Feed Pump

At one time it was my good fortune to act as watch engineer in a small modern central station situated on one of the Great Lakes. There were four vertical water-tube boilers of 5000 sq.ft. of heating surface each, often worked to 300 per cent. rating. The engine room contained two 1000- and one 2500-kw. turbo-generators, exhausting into jet condensers when desired, but in winter the exhaust was used to supply a district heating system. There was one motor-driven three-stage centrifugal boiler-feed pump, with a rated capacity of 200 gal. per min. and also a turbine-driven pump of the same size and capacity, but the turbine was unable to drive the pump fast enough even with the governor cut out of service, so it was little used. There was one other pump of the duplex type, used for general service, which could be used as a boiler feeder, but was of a light pattern and not suitable for such hard work.

One morning in midwinter when the mercury was at zero, I went on watch at 8 o'clock and found everything going at top capacity, but pretty soon things began to happen in rapid order in the boiler room—the feed pump failed to supply enough water, and it went out of sight in all four gage-glasses. You can imagine my feelings at finding this condition and all the pumps working. I recalled that the chief once remarked in a casual way that an engineer was expected to keep the plant running and not to see how quick he could shut it down.

Fortunately, I remembered in time that the delivery of a centrifugal pump falls off rapidly with a rise in temperature of its feed water, and finding that the water in the open heater was unusually hot, I lost no time in opening the bypass on the heater and sent cold water to the pumps. Then I went into the boiler room to watch results, which were not long in coming, for the water bobbed up in one glass after the other and the excitement was over. This was my first experience with a centrifugal boiler-feed pump, and I knew all the time that the capacity of a centrifugal pump changed with a change in temperature—but I didn't think, which is the trouble with a lot of us. R. B. Goold.

Leadville, Colo.

Climbing a Smoke-Stack

I saw three fellows climb a stack that had no ladder on it in a way that seemed to me far from safe. They passed a rope four times round the stack, then hooked three pullies on, at equal distances apart and each pulley on a different turn of the rope. Next, they pushed the ropes up the stack by means of long poles. When they had them up as far as they could reach, they were drawn up to the pulleys in "bos'n chairs" by other men on the ground. They then pushed another set of ropes up in the same way after making themselves secure to the first set. By repeating this process several times they reached the top of the stack.

Of course the coming-down part was easy as they were let down by the men below from a pulley on some kind of a grappling hook on the top of the stack like painters use on a house, and after they got down this was thrown off the stack. D. R. Hibbs.

New York City.

Inquiries of General Interest

Relative Properties of Copper, Iron and Zinc Wires—What are the relative properties of copper, iron and zinc wires for use as electrical conductors? M. L.

The relative electrical conductivities for equal cross-section are as 100 for copper, 17.4 for iron and 27.2 for zinc wire. The relative specific gravities are as 8.93 for copper, 7.86 for iron and 7.15 for zinc. The tensile strength per square inch of cross-section of copper wire is about 50,000 lb., of iron wire about 100,000 lb., and of zinc wire about 18,000 pounds.

Deflection of Water Tubes Away from Heat—What causes tubes of water-tube boilers to become bent away from the fire? J. A. S.

The most plausible reason given for deflection from the fire is that greater temperature attained by the fire side of the tube causes a greater expansion of length, and having elongation of the tube resisted by the headers, greater expansion on one side causes the tube to act like a strut or column that is eccentrically loaded, resulting in deflection of the tube away from the side that, from greater elongation, receives the greatest stress of longitudinal compression.

Cost of Leakage of Steam—What would be the daily loss from continuous leakage of steam at 100 lb. boiler pressure through an aperture of 0.1 of 1 square inch for 10 hours per day, where under actual conditions the evaporative economy of the boiler is 7 lb. of water generated into steam at 100 lb. gage pressure per pound of coal and the cost of coal $6 per ton of 2000 lb.? P. H.

Napier's approximate rule for the flow of steam into a pressure less than 58 per cent. of the initial absolute pressure is: Flow in pounds per second = absolute pressure × area of aperture in square inches ÷ 70. Accordingly, the discharge would be approximately $(100 + 15) \times 0.1 \div 70 = 0.1643$ lb. of steam per second, and the loss would amount to

$$\frac{0.1643 \times 60 \times 60 \times 10}{7} \times \frac{\$6}{2000} = \$2.53 \text{ per day.}$$

Height of Settings of Return-Tubular Boilers—What are the advantages of high boiler settings over low settings for horizontal return-tubular boilers, and what considerations determine the limit of height? H. C.

With higher settings the gaseous products of cumbustion and volatile matter liberated from the fuel are not cooled so immediately after rising from the fuel bed by coming in contact with the boiler heating surfaces that are much lower in temperature. Consequently, there may be more perfect combustion of the gases attended by higher temperature. In addition to the extra cost of higher settings, considerations that limit the height of the boiler are that the higher the boiler the less heat will be received from the fire by direct radiation, and although the heat of the fire which is not directly absorbed by the boiler is beneficial in improvement of combustion and in increasing the temperature of the gaseous products of combustion, for the same amount and condition of boiler-heating surface there will be higher temperature and therefore more waste of heat in the chimney gases. Hence the height of boiler most beneficial to economy of fuel will depend on the dimension of the boiler, kind of fuel, force of draft and rate of firing.

Actual, Apparent and Equivalent Cutoff—What is the difference between actual, apparent and equivalent point of cutoff of a steam engine? F. N. C.

In the operation of the engine, the actual point of cutting off is the point that marks the fractional part of the stroke which has been completed at the instant when the admission valve in closing to cut off the supply of steam has just covered the port. The apparent point of cutoff may be the point that appears to be the actual point of cutoff from observation of the operation of the engine or from measurements and known relative adjustments of different parts of the valve gear; or the fraction of stroke that is assumed to be completed at the beginning of the expansion line on an indicator diagram. Equivalent point of cutoff is the earlier point in the stroke where actual cutoff would take place so as to cause the expansion line of an indicator diagram to pass through the point of beginning of the actual diagram, or practically coincide with the expansion line of the actual diagram, provided there had been no reduction of the initial pressure during admission, and cutoff had occurred instantaneously or, in other words, assuming theoretically perfect admission and cutoff.

Minimum Number Threads for Screwed Pipe Connections—What number of threads of a pipe or nipple should screw into a fitting or a threaded pipe connection of a boiler? G. M.

Screwed connections should have the minimum number of standard pipe threads required by the A. S. M. E. Boiler Code for threaded openings in boilers for 1-in. pipe or larger, as per the following table:

MINIMUM NUMBER OF PIPE THREADS FOR CONNECTIONS TO BOILERS

Size of pipe connection, In.	1 & 1¼	1½ & 2	2½ to 4 inclusive	4½ to 6 inclusive	7 & 8	9 & 10	12
Number of threads per in	11½	11½	8	8	8	8	8
Minimum number of threads required in opening	4	5	7	8	10	12	13
Minimum thickness of material required to give above number of threads, in	0.348 = 11/32 +	0.435 = 7/16 −	0.875 = 7/8	1 = 1	1.25 = 1¼	1.5 = 1½	1.625 = 1⅝

If the thickness of the material of a boiler is not sufficient to give the designated number of standard pipe threads, there should be a pressed-steel flange or steel plate properly constructed and riveted to the boiler so as to give the required number of threads.

Lift of Valve To Obtain Full Opening—How much must the disk of a globe valve be raised off the seat to obtain full opening or the same cross-section of valve opening as the cross-sectional area of the diaphragm opening? J. D.

When the valve disk has a flat seat for covering a square-edged opening of the diaphragm, the area of the valve opening = circumference of the diaphragm × rise of the valve. Calling d = diameter of the diaphragm opening and l = lift of the valve, the cross-sectional area of the valve opening would be $\pi \times d \times l$. As the cross-sectional area of the diaphragm opening would be $\frac{1}{4} \pi d^2$, then for equality of areas, $\pi dl = \frac{1}{4} \pi d^2$, or $l = \frac{1}{4} d$; that is, for equal areas the lift must be equal to one-quarter of the diameter of diaphragm opening. When the valve seat is beveled to an angle of 45 deg., for equality of areas the lift of the valve must be about 36 per cent. of the diameter of diaphragm opening. It is not to be assumed, however, that equal projected areas in the different forms of valve seat will give the same coefficient of discharge, for that is influenced by the direction of flow of the gas, vapor or liquid in passing through the valve and also by the size, roughness and form of the shell or globe and the form and finish of the disk and its seat.

Recent Developments in Air-Pump Design*

By E. P. JONES

Reviews the chief progress in the design of air pumps from the Edwards reciprocating type to the newest multijector pump of Maurice Leblanc, which has many advantages over the well-known Leblanc hydraulic air pump. The paper is one of the most valuable yet presented on this auxiliary so important to turbine economy.

WITH the earliest types of surface-condensing equipment it was usual to employ one pump for removing both the condensate and air from the condenser. This pump was known as a "wet" air pump, and a good example of this type is the Edwards air pump, one of the most efficient of its class. The chief advantages of this type of pump are: (1) Low power required for driving; (2) positive action and consequent stability; (3) ability to cope with excessive air leakages. While the Edwards pump is still an excellent pump for units up to, say, from 3000 to 4000 kw., it must be remembered that, with the ever-growing size of power units, its disadvantages should be kept in view. For large units with Edwards pumps it is necessary that they should run at a very low speed, and consequently they are very cumbersome and take up a large amount of floor space.

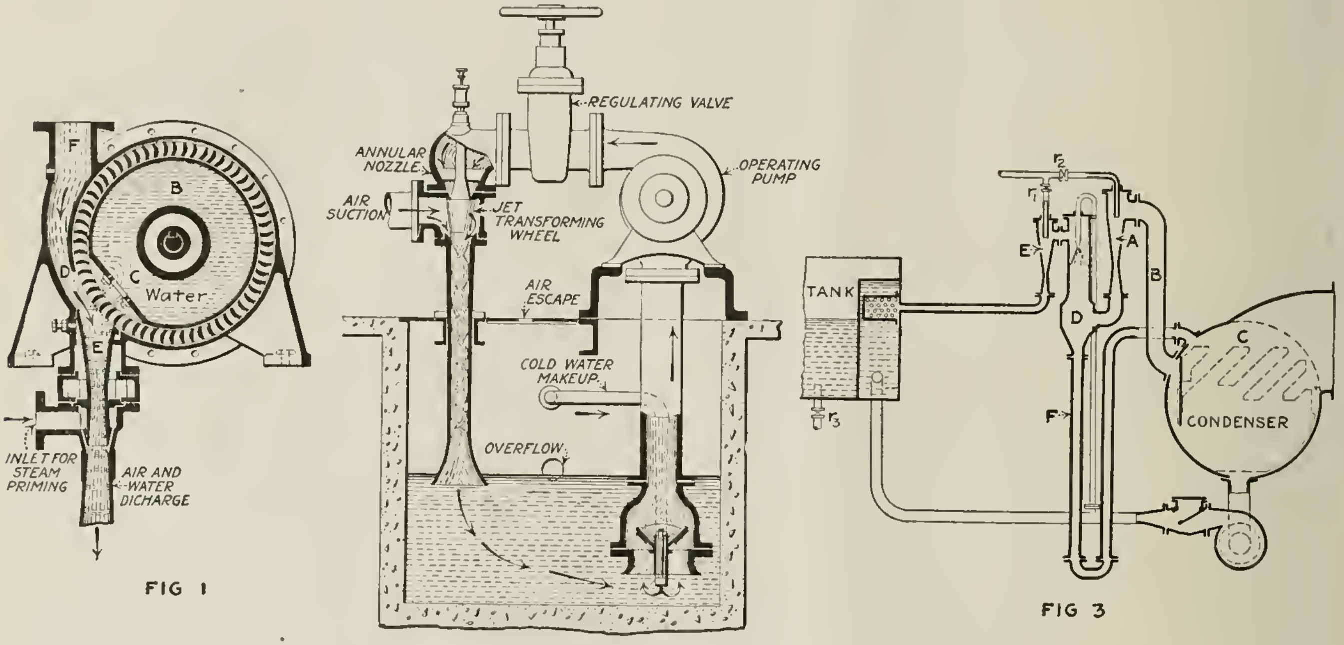

FIG 1

FIG. 2

FIG 3

FIGS. 1 TO 3. TYPES OF AIR PUMPS AND THEIR CONNECTIONS

Fig. 1—The Leblanc air pump. Fig. 2—Worthington ejector air pump. Fig. 3—French type of ejectair air pump

With jet plants the Edwards pump is sometimes used as a dry air pump. It is necessary, of course, to provide a small quantity of water for sealing purposes. Volumetric efficiency in this pump varies considerably with the degree of vacuum required and decreases as the vacuum increases from about 50 per cent. at 3½ in. absolute pressure to 18 per cent. at 1 in. absolute pressure. Another system is that in which a dry air pump of the reciprocating type is used to remove the air and uncondensed gases and a separate pump to remove the condensate. The advantages and disadvantages of this system are the same as for the Edwards air pump, but the efficiency is rather better.

Previous to the introduction of the steam turbine condensing-plant equipments were furnished with air pumps of one or other of the types mentioned, but as soon as the turbine became a commercial proposition it was necessary to look for a type of pump having features specially adapted to its requirements. With turbine installations it is essential to use a high vacuum in the condenser, whereas with steam engines of the reciprocating type a vacuum of more than 26½ in. was seldom required. In fact, it is questionable whether using a vacuum higher than 26½ in. would not be considered a disadvantage. With the turbine, however, a vacuum less than 27 in. is rarely asked for, and sometimes the specified figure is as high as 29.25 in. with the standard barometer reading of 30 in. In considering these figures, due allowance must be made for the altitude of the place. The most economical vacuum for a turbine installation depends on a variety of things, and each case has to be considered on its merits.

On reference to steam tables it will be seen that an increase in vacuum from 27 in. to, say, 29 in., other conditions, as air leakage, remaining the same, necessitates an increase in the capacity of the air pumps from 1.00 to 3.25, which for a large installation with Edwards or reciprocating dry air pumps is a very serious matter. Therefore various types of rotary pumps, which are specially suitable for dealing with large volumes of air at low tension, have been designed since the adoption of the steam turbine, several of which have proved very successful. The general design of these pumps is much the same, in so far as they use a certain quantity of what is termed "operating water," for which various devices have been invented to cause this water to move in such a manner as to entrain the air from the condenser and discharge it to the atmosphere. Perhaps one of the best-known rotary dry air pumps is the one invented by Prof. Maurice Leblanc. It has been used to a large extent all over the world, and its action is shown by Fig. 1. This pump is capable of maintaining a very high vacuum, and for this reason, coupled with the fact that it

---

*From a paper before the Institution of Engineers and Shipbuilders, Scotland, reported in "Engineering" (London), Sept. 7 and 14.

is very simple in construction and not likely to get out of order, it has been largely used for turbine installations. It cannot be claimed for this pump—or, indeed, for any type of rotary air pump—that it can successfully deal with an excessive air leakage, but consideration will show that this quality is not essential in the case of turbine installations where air leakage is reduced to a minimum by the adoption of steam- or water-sealed glands where the shaft passes out of the turbine casing. With a surface-condensing plant it is only possible for air to be brought into the system by the feed water and carried over with the steam, or by leaking in at the joints. With jet plants, the air brought in with the injection water has to be allowed for in addition to the above, and it is for this reason that the air pump on a jet plant requires to be larger than that for a surface-condensing plant doing the same steam duty.

The power required to drive these pumps is rather higher than that required for an Edwards or other good type of reciprocating air pump, and consequently a good deal of attention has been paid recently to another type of pump which would incorporate the simplicity and compactness of the rotary pump and the low-power consumption of the Edwards and other reciprocating pumps. The general trend of thought seems to have been in one direction, and there are now on the market and in commercial use air pumps operating on the ejector principle. Nearly all the leading condenser manufacturers now construct air pumps of this description.

THE NEW EJECTOR AIR PUMP

The Worthington Pump Co., Ltd., London and Newark, manufacture a patent hydraulic vacuum pump on the ejector principle, as illustrated by Fig. 2, which consists of: (1) The injection head, (2) the air-suction chamber, (3) the rotary wheel, (4) the throat and tail pipes. The operating water passes between two nozzle rings, and the cone of water passes between the body of the wheel and the outer sleeve, impinging on the inclined surfaces of the vanes, thus imparting a rotary motion to the wheel. To operate the pump it is necessary to provide a certain amount of sealing water, which is supplied from a tank situated as conveniently as possible to the pump. The sealing water takes up a certain amount of heat from the air and water vapors withdrawn by the air pump, and a piping arrangement is provided for withdrawing a certain amount of this water by means of a bypass connection on the operating pump discharge, this bypass being fitted with a controlling reflux valve. The quantity of water withdrawn in this manner is replaced by makeup water drawn from the circulating inlet-piping or an independent supply, thus cooling the water used in the cycle of operation. This apparatus is doing regular service on one of the turbo-alternator groups at the Glasgow Corporation Power Station at St. Andrew's Cross. A number of installations have also been supplied to other concerns.

Willans & Robinson, of Rugby, manufacture the Willans-Muller ejector air pump, which is operated by the circulating water, either on the series or shunt system. With the series system the whole of the circulating water passes through the ejector before entering the condenser. With the shunt system only a portion of the cooling water passes through the ejector, and, after use, is returned to the pump suction or the source of supply. A third method of operating this ejector is by the separate-pump system, in exactly the same manner as described in referring to the Worthington pump. The whole plant is very similar to that made by the Worthington Pump Co. The Glasgow Corporation has a set of this apparatus at work at Pinkston Power Station, and good results have been obtained, and a second set is just being installed at St. Andrew's Cross.

Another type of ejector air pump is that manufactured by Hick, Hargreaves & Co., Ltd., Bolton, under license from the Mason Breguet, Paris. This is really two ejectors working in series, with an auxiliary condenser placed between the first and second stage of the ejectors. A number of these air pumps, termed "ejectairs," have been supplied to, or are under construction for, the French Navy. Referring to Fig. 3, it will be observed that the primary ejector *A* is placed in direct communication with the main condenser *C*, and extracts the aërated vapor, being operated by a single steam jet or nozzle r_2. The mixture of steam and partly compressed vapor is then discharged to the auxiliary condenser *D*, and the water returned to the main condenser to be dealt with by the extraction pump. The second-stage ejector *E* is coupled up to the auxiliary condenser, and draws the air away, discharging it to the feed tank. An automatic air-inlet valve is fitted to the auxiliary condenser, to regulate the absolute pressure therein. It is claimed that taking air from the atmosphere in this manner materially assists the stability of the plant, and also renders it more flexible. These *ejectairs* are designed for working with steam pressures at 55 lb. per sq.in. or above, and with a special arrangement of nozzles lower pressures can be used in the primary ejector, although the advantage of this is not apparent if it is impossible to work the other ejector under the same conditions, neither is it clear whether this can be accomplished or not.

The curves, Fig. 4, show the performance of an *ejectair*. Steam to the ejectors had an absolute pressure of 125 lb. per sq.in., and the steam consumption is given as 194 lb. per hour, of which 129 lb. is recoverable. The apparatus worked in conjunction with a small jet condenser, dealing with 94 gal. of injection water per minute. Curve 1 gives the vacuums obtained with water leaving the condenser at a temperature of 91.4 deg. F. (33 deg. C.), and the auxiliary condenser out of action; curve 2 the volume of air dealt with in cubic feet per hour; curve 3 the vacuums obtained with given air leaks, and the water leaving the main condenser as for curve 1, but with the auxiliary condenser supplied with cooling water at 66.2 deg. F. (18 deg. C.); and curve 4 the volumes of air dealt with under the same conditions. It was calculated that the air coming in with the injection water and at leaky joints amounted to 1.102 lb. per hour (0.5 kg.).

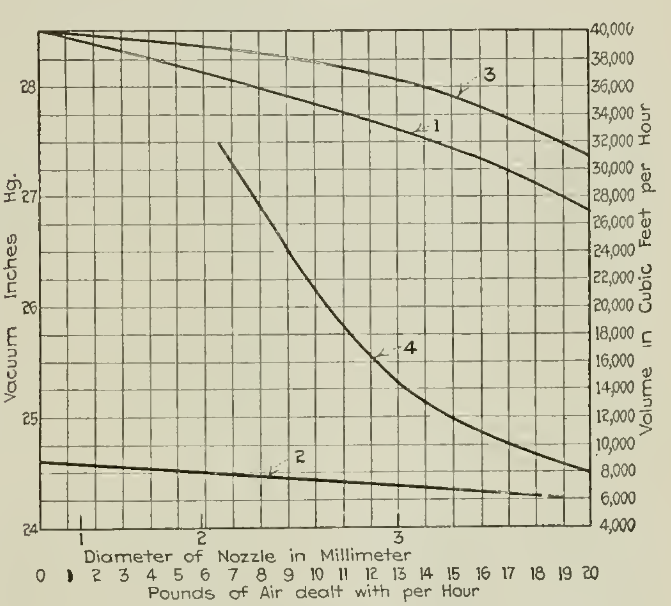

FIG. 4. PERFORMANCE OF AN EJECTAIR

The British Westinghouse Electric and Manufacturing Co., Ltd., Manchester, and the Mirrlees Watson Co., Ltd., Glasgow, manufacture an ejector air pump, under license from the Société Anonyme Westinghouse, Paris and Le Havre, which is another invention of Maurice Leblanc. It is the outcome of many months of arduous research work, during which time innumerable difficulties were surmounted by the inventor, with the result that a really first-class ejector air pump has been evolved. Figs. 5 and 6 show the general arrangement of this apparatus. It will be noticed that the pump is arranged to work in two stages, and the steam is admitted to the second stage of the ejector by opening the stop valve *C*. Immediately *C* is opened, steam fills the annular space behind the nozzle plate, and finds its way into the throats of the group of nozzles *Y* attached to this plate; it then passes along the steam pipe which supplies the first-stage nozzles *X*, which are also attached to a nozzle plate. The supply of steam in this set of nozzles is controlled by the stop valve on the steam-supply pipe. The pump is connected to the condenser at the branch *D*, which is the air-inlet branch. At the entrance to each of the steam spaces fine wire-gauze strainers are fitted to prevent any foreign matter, which may have primed over with the steam from the boilers, from entering the nozzles, thereby intercepting any stoppage in the nozzle throats, and consequently a loss of vacuum. These nozzles are securely locked to the nozzle plates. The mixture of air and steam is discharged at the mouth of the cone *Y* and led away to the boiler-feed tank, so that the heat units contained in the operating steam can be reclaimed by heating the feed water. To start the pump to work, it is only necessary to open up the steam valve *C*, and the vacuum will at once begin to increase in the condenser or other vessel to be evacuated. When the vacuum gage becomes stationary, the first-stage steam-inlet valve is opened up to bring the vacuum to a maximum. A very ejector, which might be considered negligible. Beyond this, the whole of the heat in the steam can be utilized to heat up the boiler-feed water, and in order to obtain full benefit from the apparatus it is highly desirable to use the discharge from the ejector for heating purposes of some description. Thus both the steam and air can be made to do useful work. In view of this it must not be forgotten that when an ejector of this type is specified as requiring so many pounds of operating steam per hour, this is only the apparent quantity; the actual quantity is really far less, since the great majority of heat units in the steam are still available for further work. The actual heat units recovered can easily be calculated from steam tables, since it is known that the steam and air leave the ejector at a pressure of from 10 lb. to 12 lb. per sq.in. by gage. It will be observed that with a Leblanc multijector an auxiliary condenser is not required, and in this respect it differs materially from the "Berguet" *ejectair*. The employment of an auxiliary condenser has the disadvantage that the total

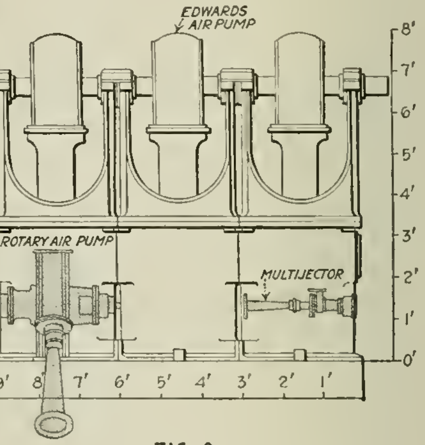

FIG. 8

FIGS. 5 TO 8. MAURICE LEBLANC'S LATEST MULTIJECTOR AIR PUMP AS MADE BY THE BRITISH WESTINGHOUSE ELECTRIC AND MANUFACTURING CO.

Figs. 5 and 6—Two forms of the Leblanc ejector. Fig. 7—Behavior of flow from the nozzle. Fig. 8—Showing comparative sizes of Edwards, Leblanc rotary and the multijector types of air pumps for a given capacity

important feature in this pump is the absence of moving parts. The simplicity of the apparatus is even more remarkable than that of the Leblanc rotary pump.

The advantages claimed are as follow: (1) Extreme simplicity; (2) the small amount of energy required for operating purposes; (3) the high efficiency obtained; (4) ease with which starting can be effected, and the small amount of attention required while at work; (5) ability to produce the highest possible vacuums; (6) stability. In scanning these claims we can pass over the first, which as already mentioned, is obvious; there are simply two steam valves to open. The second deserves some consideration. The operating steam in passing through the nozzles decreases in pressure, and consequently in temperature, and also, after passing through the nozzles, does work in accelerating the velocity of the air, increasing its temperature and compressing it. There is also a small amount of heat lost due to friction in passing through the diffuser portion of the heat units of the steam used in the first-stage ejector, which amount to an appreciable percentage of the total heat units used on the whole apparatus, are dissipated and lost. The makers give this percentage as about 33. Another reason for dispensing with the auxiliary condenser will be apparent from the following. In all steam-operated ejectors one of the difficulties that have to be contended with is the fact that the steam leaves the nozzles at a velocity varying from about 3000 to 3600 ft. per sec., while the velocity of the fluid to be entrained is practically nil. This is the cause of considerable loss of efficiency in any ejector, but if an auxiliary condenser be used the defect is doubled, because the velocity of the fluid to be entrained, which has been imparted to it by the operating steam during its passage through the first-stage ejector, is dissipated and lost as soon as it enters the condenser. The cooling water used on the auxiliary condenser has to be dealt with by the condensate pump, thus increasing the power absorbed by the plant. When working with surface condensers, this water must be of good quality, as it has to be returned to the boilers.

The third claim relates to efficiency. It is well known that ordinary single-stage ejectors only work well when the compression ratio is as 1: 7, and it is partly for this reason that the Breguet Co. has introduced the auxiliary condenser, so that the vacuum obtaining in this condenser is about 25.6 in. with the barometer at 30 in., the compression being approximately as 11: 76, or, roughly, 1: 7. The over-all efficiency of this plant is, therefore, apparently still further reduced, because air is admitted from the atmosphere into the auxiliary condenser, which is under a vacuum of 25.6 in., and this, together with the air from the condenser, has also to be ejected by the secondary ejector to the atmosphere.

When Professor Leblanc set out to design his ejector he foresaw the possibility of using an intermediate condenser, but he also appreciated its disadvantages and decided to do without it if at all possible. At the same time he knew that it was essential to use two stages in order to get a stable and efficient ejector. With this end in view, certain steam nozzles were designed on the lines of the formulas of Professor Rateau, and the action of the steam issuing from these nozzles when under high vacuum was directly observed. The result is shown by Fig. 7. The steam issuing from the mouth of the nozzle expands and contracts alternately, ultimately assuming a section of constant area. It was found that a number of these nozzles grouped together gave far better results than a single nozzle of the same throat area as the group of nozzles. The reason for this is to a large extent due to the fact that the alternate increasing and decreasing of the cross-sectional area of the steam stream is minimized by the contact of one steam stream with the next, when groups of nozzles are employed, and this helps considerably to increase the surface available for the entrainment of the air and gases. This entrainment is carried on mainly by friction, and it will be seen that if an appreciable amount of gas has to be dealt with, the frictional surface exposed to the gas has to be as large as possible. It is also inversely proportional to the density of the gas or fluid.

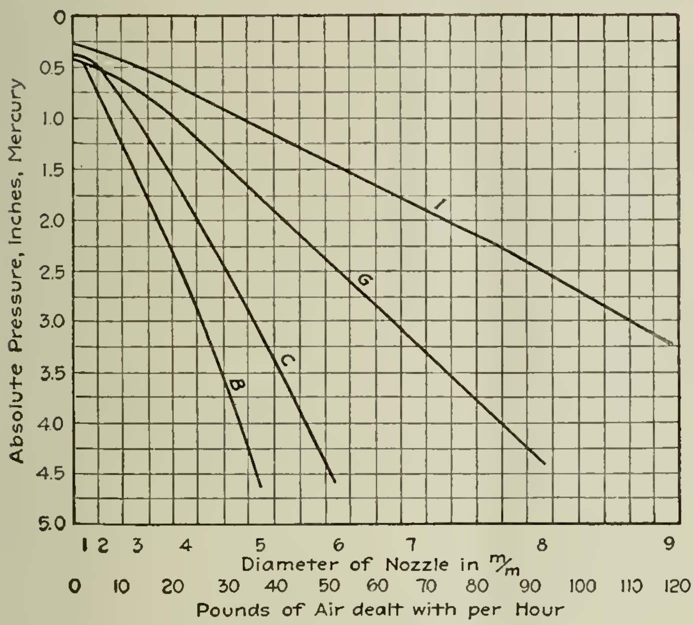

FIG. 9. CAPACITIES OF VARIOUS SIZES OF MULTIJECTOR PUMPS

The number and size of the nozzles depends entirely on the space available in the diffuser, and keeping within the limits of workshop practice. The smallest number employed by the Mirrlees Watson Co. is three, each of which has a throat diameter of 1 mm. These are first-stage nozzles. On the largest size of pump, and in the second stage, the number of nozzles is 30, and these have a throat diameter of 5.2 mm. when using operating steam at 90 lb. per square inch.

Professor Leblanc, in his paper of 1911 to L'Association Technique Maritime, says that "the operating steam entrains the air by friction. During entrainment it is the velocity of the steam which is utilized, and not its kinetic energy."

Calling M the weight of operating steam used per second, V its velocity at the outlet of the nozzles, m the weight of air drawn in per second, and W the velocity of the mixture of air and steam, then

$$MV = (M + m)\ W$$

The ratio of the kinetic energy, $\frac{mW^2}{2}$, of the air drawn in to the kinetic energy, $\frac{MV^2}{2}$, contained in the operating steam as it comes out of the nozzles can therefore be stated as

$$\frac{mW^2}{MV_1^2} = \frac{mM}{(M + m)^2}$$

so that when $\frac{m}{M} = 1 \quad \frac{1}{2} \quad \frac{1}{3} \quad \frac{1}{4} \quad \frac{1}{5}$

$$\frac{mM}{(M + m)^2} = 0.25,\ 0.222,\ 0.187,\ 0.160,\ 0.139$$

This shows that if the utilization of the kinetic energy is to be the basis of the design, then for maximum efficiency it is necessary to bring the ratio $\frac{\text{air dealt with}}{\text{operating steam used}}$ as near to unity as possible.

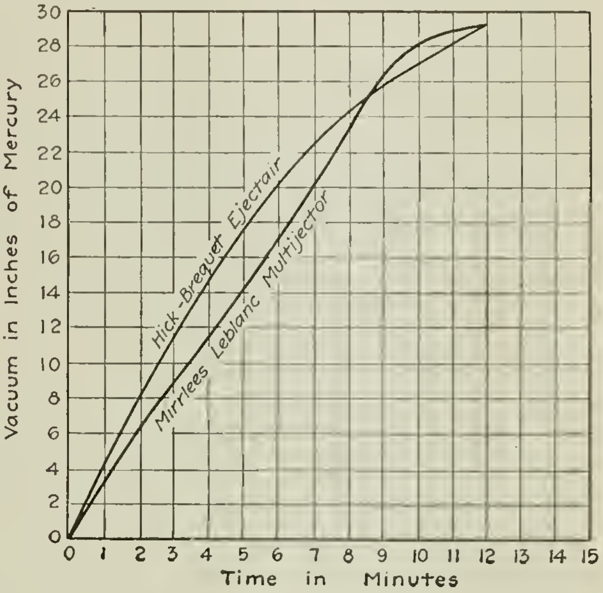

FIG. 10. TIME REQUIRED TO START HICK-BREGUET EJECTAIR AND MIRRLEES-LEBLANC MULTIJECTOR

M. Leblanc continues: "We tried to diminish the loss of kinetic energy by producing at the entrance of the diffuser a higher vacuum than was necessary, so that the fluid drawn in came in contact with the operating steam with a considerable velocity. If the efficiency of the diffuser could be brought almost to unity, we could add considerably to the over-all efficiency, but this has been found to be impracticable. Following on this, it was suggested to use puffs of steam after the manner of steam coming out of locomotive chimneys, but the complications involved in making arrangements for stopping the inlet of air during each puff were such that it would have been easier to use a centrifugal compressor. Afterward we tried to compensate for the bad efficiency due to frictional entrainment by transforming heat into kinetic energy in the nozzles. Superheating the operating steam, although so useful for turbine work, is, however, not good for an ejector, because it is more difficult to effect compression in the diffuser, which outweighs the advantages obtained in the nozzles. The next scheme was to use hot water in the nozzles, but this also proved unsuccessful."

After numerous other trials it was decided that entrainment by friction was most economical, and various types of diffusers and different groupings of nozzles were experimented with, until the present ejector, as shown in Figs. 5 and 6, was decided to be the most suited for condenser work. To go through the various stages in detail which led up to this design would take up too much time. With the form of ejector adopted it has been found that the efficiency of the nozzle is on an average 85 per cent., while that of the diffuser is 70 per cent. It will be seen that this ejector agrees very well with the ideal ejector which Professor Leblanc had in his mind. The first stage, which consists of a small group of nozzles, serves a triple purpose, inasmuch as it effects a certain amount of compression, heats up the entrained air, and gives it considerable velocity, and consequently an increase in momentum. The second stage has a larger number of nozzles, and it is here where the major portion of the work is done, the air being compressed from approximately 26 in. vacuum up to something more than atmospheric pressure. To be more accurate, the steam used in the first stage is about 5 per cent. of the total.

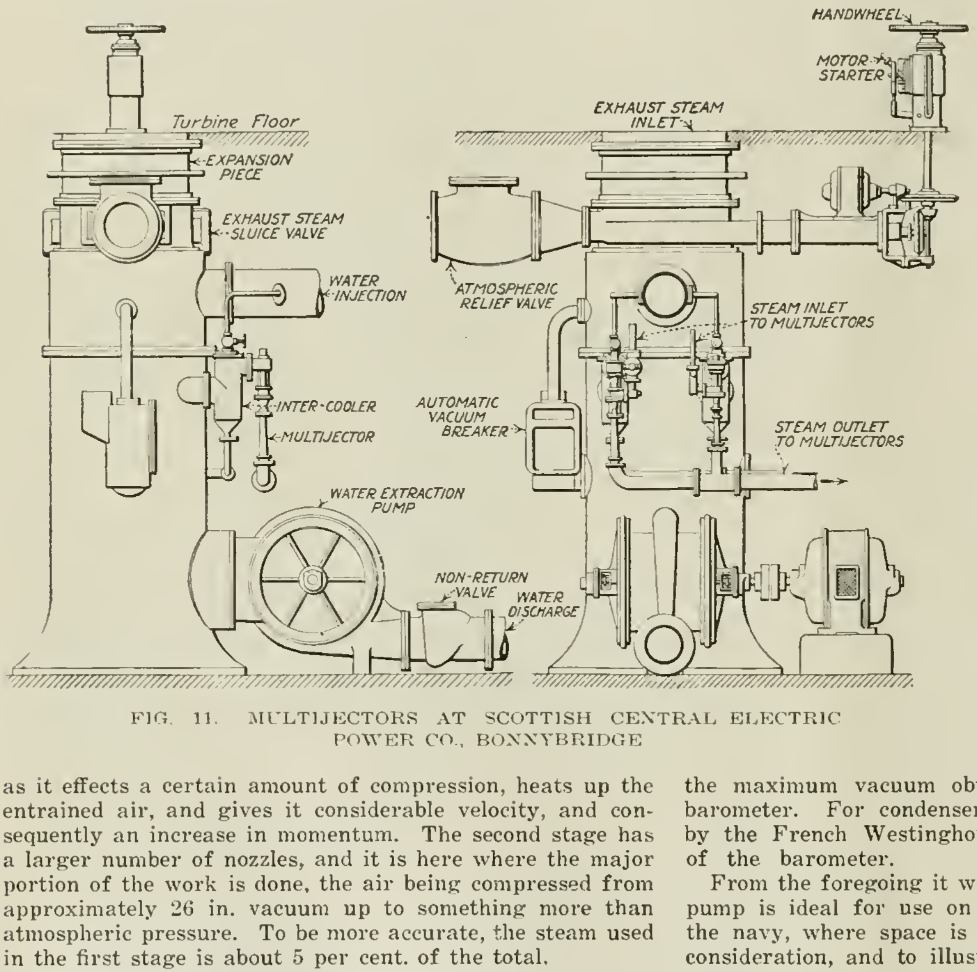

FIG. 11. MULTIJECTORS AT SCOTTISH CENTRAL ELECTRIC POWER CO., BONNYBRIDGE

In support of the fourth advantage which this air pump is supposed to possess, the following figures were obtained on the French torpedo-destroyer "Boutefeu." The turbines were stopped, but steam was on the glands. The volume to be evacuated was about 635 cu.ft. After 1 min. the vacuum was 6 5/16 in., 2 min. 15 in., 3 min. 22 13/16 in., 4 min. 25 9/16 in., 5 min. 26¾ in., and 6 min. 27 9/16 in. The theoretical vacuum corresponding to the temperature of the water, 67.1 deg. F.; namely, 28¼ in., was attained in 11 min. It was also arranged later to allow certain known air leakages to enter the condenser. With a 5-mm. nozzle, which passes 36.2 lb. of free air per hour, the vacuum dropped only ⅜ in. With a 15-mm. nozzle, which is equivalent to 326 lb. of air per hour, the vacuum was 21¼ in. With an inch cock full open it took 11 min. for the vacuum to fall to 12¼ in., at which figure the mercury column remained steady. On closing the regulating valve below the nozzle, the vacuum at once rose and attained the maximum almost immediately. There is a central station near Glasgow where this type of apparatus is at work with a multijet condenser. Sometimes when changing machines there is liability partially to lose the water for a minute or so, but none of the staff ever have to trouble about the ejectors, and as soon as the water comes back again the vacuum at once builds up, and the set is never shut down through failure of the air pumps. As a matter of fact, in the case above stated, it is highly probable that during the period that the water supply to the condenser is very small there is an air passage between the water spaces of the other condensers in the station and the multijet plant which would allow of a very excessive quantity of air getting into the condenser on load. This also shows that stability, the sixth claim, is another salient point. That high vacuum can be obtained is proved by the fact that this apparatus is now being used in the French Navy and mercantile marine, as well as on some land installations for refrigerating purposes, and installations are at work where the maximum vacuum obtained is within 1 mm. of the barometer. For condensers the best results yet obtained by the French Westinghouse company are within 5 mm. of the barometer.

From the foregoing it would appear that this type of air pump is ideal for use on board ship, and particularly in the navy, where space is so valuable and weight of such consideration, and to illustrate this point Fig. 8 has been produced, and represents to the same scale an Edwards air pump, Leblanc rotary air pump, and Leblanc multi-

TABLE I. OFFICIAL TEST OF NO. 18 M. J. CONDENSING PLANT WITH MOTOR-DRIVEN WATER-EXTRACTING PUMP, 1-SIZE "G" AND 1-SIZE "I" MULTIJECTOR AIR PUMP INSTALLED AT THE SCOTTISH CENTRAL ELECTRIC POWER COMPANY, LIMITED, BONNYBRIDGE

Duty—50,000 lb. steam per hour.
Vacuum—28.5 in. (barometer 30 in.).
Injection water—3,800 gallons per minute, temperature 65 deg. F.
Air pump capacity—84 lb. air per hour with guaranteed vacuum and water temperature.
Large ejector to operate condenser alone on loads over one-third and up to two-thirds full load.
Small ejector to work alone on loads of one-third full load and under.
Both ejectors to work on loads over two-thirds full load.

jector for a steam duty on a surface condenser of 40,000 lb. per hour, water at 60 deg. F., vacuum 28½ in., and barometer 30 in. The weights are approximately 20,832 lb., 4480 lb., and 97 lb., respectively. For land work it is equally suitable, and will soon supersede the rotary pump in many power stations. For sugar refineries, chemical and other allied works it should prove exceptionally attractive and take the place of many reciprocating dry air pumps.

It may be advisable to point out here that this pump is purely a dry air pump, so that for surface condensers an additional water or condensate pump is still required, and for jet plants the usual extraction pump.

Fig. 9 shows the air-dealing capacity of various sizes of multijector pumps taken from the actual tests. The maximum vacuum in each case is equivalent to the theoretical, the slight difference at the origin of the curves being due to the different test conditions.

The table of tests, I, is taken from a plant installed at the Scottish Central Power Station at Bonnybridge at a date six months after the plant was put on commercial load. This company has just decided to order another plant, and has specified Mirrlees-Leblanc multijector air pumps.

Fig. 10 shows the time taken to start up a Hick-Breguet *ejectair* and a Mirrlees-Leblanc multijector.

There is no doubt that considerable improvements have been effected in air-pump design during the last few years, nevertheless there is still room for further progress, and it is to be hoped that when the British engineer has time once again for research work we shall have to drop all our present-day notions of efficient air pumps for a type which will render all others obsolete.

Fig. 11 shows installation of multijector air pumps at Scottish Central Electric Power Co., Bonnybridge.

Secretary for Joint Activities of Engineering Societies

For economy of administration and the furtherance of coöperation among organizations representing the profession, the United Engineering Society, the Engineering Foundation and the Engineering Council recently decided to join in one suite of offices in the Engineering Societies' Building and engage a joint secretary. For this position the engineer selected is Alfred Douglas Flinn, now deputy chief engineer of the Board of Water-Supply of the City of New York.

The United Engineering Society was formed some years ago by the National Societies of Civil, Mining, Mechanical and Electrical Engineers to coördinate joint activities and provide for holding property in common. This body acts as the holding company for the four founder societies and is landlord of the Engineering Societies' Building in New York, in which the founder societies have headquarters. In it also is vested the title to the library housed in the same building, which, with the recent addition of the collection of the American Society of Civil Engineers, is now the most important engineering library in the country.

The Engineering Foundation Board was created, as a department of the United Engineering Society, to administer the endowment made by Ambrose Swasey three years ago for the support of engineering research for the benefit of the profession and of humanity. The large sum of money he gave will form, it is hoped, the nucleus to which other gifts will be added.

The last of the three organizations which are to have a joint secretary is the Engineering Council. For years it has been recognized that there were certain activities affecting engineers which could not be properly handled by any one of the individual engineering professional societies. To meet this need there was created during the past summer the Engineering Council "for the proper consideration of questions of general interest to engineers and to the public, and to provide the means for united action upon questions of common concern to engineers."

Mr. Flinn was born in New Berlin, Penn., in 1869, and was graduated from Worcester Polytechnic Institute in 1893. In August, 1895, he became a member of the engineering staff of the Metropolitan Water-Works, Boston, and remained with that organization until 1902. He rose steadily until he became principal office assistant under the chief engineer, Frederic P. Stearns, in charge of designs of the Wachusett Dam and other structures coming under the authority of the Metropolitan system. During the latter years with this organization he also lectured on water-works and sewerage in Lawrence Scientific School, Harvard University.

On leaving the Metropolitan Water-Works Commission, he became managing editor of the *Engineering Record*, and continued in that capacity until August, 1904, when he was appointed general inspector of the Croton Aqueduct Commissioners. About a year later, upon the organization of the Board of Water-Supply of the City of New York, which was established to build the new Catskill Aqueduct and its appurtenant structures, he became department engineer in charge of the headquarters department. He continued as department engineer until August, 1914, when he was made deputy chief engineer. He has continued in that capacity until his election to the secretaryship referred to in this article.

© Underwood & Underwood

ALFRED DOUGLAS FLINN

Mr. Flinn brings to his new position a broad executive and organizing experience. He is a member of the board of direction of the American Society of Civil Engineers and chairman of its committee on publications.

In relation to modern engineering no one man can be expected to possess a working familiarity with the whole. In a particular sense all engineers are specialists, though many have a more comprehensive grasp than others. To produce the best it is above all things essential that our knowledge exceeds the demands of the task in hand. It is therefore urged that the most effective method by which to acquire the needed broadening of knowledge is by continual reading and study; otherwise—notwithstanding individual attainments—the best become "outsiders" and back numbers.

Dr. Garfield on the Fuel Situation*

I shall be duly appreciative, gentlemen, if I may be privileged to answer questions, as far as I am able, rather than to undertake to set forth to you matters concerning the Fuel Administration.

The United States Fuel Administration was appointed by the President of the United States in accordance with the provisions of an act of Congress known as the Lever Act. Food and Fuel were provided for by that same act. In the 25th Section of that act, provision was made for the Fuel Administrator. The President has given the Fuel Administrator all the power that he himself possesses under the act.

In setting up an organization, the difficulty was one that you gentlemen will appreciate, who have at any time engaged in projecting an organization to carry out some large purpose, especially if the carrying out of that purpose has run with the period, or run with the activity of organization. To build your house and live in it at the same time is no easy task. We were compelled to adopt a working hypothesis to govern us in our organization and to proceed upon that hypothesis, in the hope that our plan would be a workable one.

Organization Scheme

Briefly, we set up the Federal control here in Washington, appointed the State Fuel Administrators in each of the states of the United States and in the District of Columbia, requested each one of those fuel administrators in turn to appoint county and municipal administrators, vested in the state fuel administrators full power to distribute the coal within the state, made it clear that so far as the county and municipal administrators and their committees were concerned, the administration here at Washington delegated full power, both in appointment and in control to the state fuel administrators. It was, you see, in a measure, a United States—there was the Federal, the state, the county and the municipal administration.

I am the more impressed with the significance of this organization just at the present time, because in my native state (Ohio) there has been some difficulty reflected in the morning papers, owing to the fact that Governor Cox, with an admirable zeal for distributing coal to the people and institutions of Ohio, has crossed the lines of the Federal Fuel Administrator, Mr. Johnson, thinking thereby to accomplish a good purpose. But it is very easy to see that if coal upon the tracks consigned in one direction is taken, as it may be, under the law, by the representative of the United States Fuel Administrator and diverted to an immediate need, it is impossible that there shall be anything other than confusion, if some other authority runs across that plan and undertakes also to divert coal.

Let me touch upon one policy that is reflected in the organization, and, at the same time, has intimately to do with meeting the problem presented. The United States Fuel Administration isn't responsible for the way coal is deposited in the earth. If we take the right view of it, I think we will admit that mankind is there beholden, as in all other things, to the Creator of the Universe. The coal is deposited throughout the United States in various regions, and obviously to allow our State Administrators to draw upon that coal and limit them, won't do, because in a place like Ohio, for instance, where there is coal in abundance, the State Administrator would be able to supply the people of Ohio abundantly, and might, if he were selfishly disposed, neglect those who were in states in which no coal was deposited. Therefore, from the beginning, I have pursued the plan that in governing production and distribution from the mines, the Federal, that is, the United States Fuel Administrator, must be the director. On the other hand, when it comes to distributing the coal within the borders of the state, that is a matter much better left to the State Fuel Administrator.

Speaking of bituminous coal, we are this year producing something like 50,000,000 tons more coal than we produced last year, and last year was a record year. Some of you will then say: "Why is there a shortage?" Because we needed 100,000,000 tons more than last year. The extra 50,000,000 tons which we needed, but have not had, amount to the same thing as if there were a shortage of supply. The extra demand, as you will appreciate, comes from the fact that the United States is at war, that our manufacturing enterprises must be supplied with coal, that the railroads of the country, taxed beyond their powers, must have more coal to operate as they are now operating, to say nothing of the normal increase in the call for domestic coal.

There are three factors entering into the production—first, the operators, then the mine employees, and third, the railroads. Unless each one of those is working at efficiency, we will not have maximum results in output.

About the time the Federal Fuel Administrator was appointed, the bituminous interests of the country got together and formed a national organization. Undoubtedly that organization has desired things which the Federal Fuel Administrator hasn't been able to furnish; possibly that organization may entertain ideals of policy that do not appear in the same light to the Federal Fuel Administrator, but if that latter is true, I haven't yet discovered it.

A large part of my time was spent during the first two months, and indeed much of my time is still occupied, with bringing together operators and representatives of labor, who, in certain fields of the country, are not able quickly to adjust their differences, and I have just one theme that I always present to those gentlemen when they come together, and it is this: Whatever our controversy, wherever the right lies, make sure that production continues and be not interrupted by reason of your dispute. That theme cannot be overemphasized.

Labor Has Done Its Part

I also wish here to pay tribute to labor, because the leaders, the conservative element in labor, has caught the idea not because it was enunciated by me (because I was only one voice saying the same thing), but because it is the spirit of our people at the present time that in prosecuting this great war, in meeting the emergency which we are called upon to meet because of it, labor, realizing these facts, has come forward in the very best of spirit, saying that it will not permit labor to cease to do its part. Wherever there is a failure in that program, it is because of the inevitable radical element that we find in every business in every country.

Now, I am very far from saying that no good comes out of radicalism. Human nature is so constituted that there are always some at the extreme right and some at the extreme left of every proposition; but in a time of emergency, when action is necessary, when we must spend less time in deliberation, when it is not feasible to educate everybody, as it is in times of ordinary conduct of affairs, it is perfectly obvious that the extremes must be brought together and action taken, even though the conservative thinks that we are going to wreck and ruin, and even in spite of the fact that the radical believes we are not going nearly far enough. So then, the radical element in the whole field has been a disturbing element, but it has been held in check by the great mass of the workingmen in the coal fields, and with relatively slight interruptions production has gone forward.

Now, it is a significant fact, speaking of the anthracite field, that with the total amount of labor in normal times, something like 175,000 men and boys at the mines were reduced by 25,000 because of the draft and because of the fact that employment elsewhere has appeared more attractive. But in spite of the fact that there are only 150,000 men and boys laboring in the anthracite field this year, against the 175,000 normally, the anthracite mines have produced something like 20 to 22 per cent. more coal than they produced a year ago. That plainly is a

---

*Address delivered before the Editorial Conference, Washington, D. C., Thursday, Dec. 13, 1917.

tribute both to labor and to those who are conducting the mines.

There is an element in human nature that we ought not to lose sight of, and though it is painful to comment upon it, gentlemen, it is necessary to comment upon it; the selfishness of human nature, the disposition, to use a common phrase, to hog things. Now, there has been a great deal of that sort of thing this year. It has extended into the households, people buying more coal than they quite needed; it has found its way more naturally into the factories, anticipating an increase of business, and the result is that some, many indeed, have more coal than usual, some have more coal than they need for the entire year, and some less provident, possibly because they could not provide the store ahead, are without coal.

DISCUSSION

J. Chase: Are our rivers being used to their fullest extent in the shipment of coal at the present time?

Dr. Garfield: The rivers are not being used to their fullest extent; one may say the same thing as to the railroads, but in the case of the rivers, the accustomed channels for the distribution of coal had been provided otherwise. Now, whether the railroads have in times past, by the law of protection, gotten more than their due share of the coal transportation, I am not prepared to say. I know that when it came to the question of using the rivers we were not equipped to make the maximum use of them that should have been made. And, of course, there was no time to provide the extra equipment. That is being provided for more and more, however, now.

Mr. Frost: Why is it that coastwise towns like Providence, R. I., have to pay more for coal than interior towns like Worcester and Springfield?

Dr. Garfield: Because the freights by water have gone up largely because of the fact that the ocean-going tugs have been requisitioned by the navy.

May I say in that connection that the Governor was in my office and I gave him the information (Governor McCall, I refer to), that I have just arranged within a few days with the Secretary of War and with the Secretary of the Navy coöperating, and with E. N. Hurley, of the Shipping Board, that we shall have the supply of ships necessary to transport our coal by water.

The Secretary of War stated to me that if it became necessary to do so, he would detail mine layers, too good for the operation, as a matter of fact, but nevertheless quite sufficient, to pull the barges around from the tidewater ports here to New England. Also Mr. Hurley is directing that certain boats brought down from Montreal shall be put into the New England trade; and further than that, I am making a request (this looks forward to another season) that the new shipbuilding corporation shall build for us tugs that will be ready for service by the time next season comes around.

Mr. Williams: Regarding the matter of utilities, I understand that they are put in a priority class for consumption and not for storage. I read in the paper this morning that two plants operating in large industrial centers are without a sufficient supply of coal and have asked industries to close down. What will the Fuel Administration do with utilities in that matter, and to what extent will this supply be for current use?

Dr. Garfield: The moment we receive the information that a public utility is out of coal, or in danger of being out of coal within a few days, we issue the orders to send coal to that utility.

Mr. Williams: Well, the Washington papers stated that in the Baltimore and Pittsburgh sections the Government had to request industries to close down—industries using electrical power—because of the shortage of coal. I know that the priority order puts the utilities in a class where they can get coal for current consumption (that was issued by the Food Administration, I believe); now, the point I'd like to ask is how soon can these companies get coal and to what extent will they be kept in a supply of coal, so that such an emergency will not arise and so the shipyards will not be closed down?

Dr. Garfield: Any utility that will inform us of its impending lack will receive supplies of coal; that is, we will issue the orders right off to divert to those utilities enough coal to keep them going.

Now, a severe spell of weather, such as we have just had, may defeat the arrival of that coal in time, but all we can say about that is that that is liable to happen any season, and furthermore that the utility should speak far enough ahead and speak in the right form.

A mistake is made by not coming to the right place. If the utility will let the State Fuel Administrator know the necessity, and the State Fuel Administrator will thereupon inform this office here, immediately orders will be sent out to certain specified mines.

A. L. Findley: May I ask, Dr. Garfield, as to the status of the proposal to pool quantities of the mines?

Dr. Garfield: The Ohio pool is the one that has, so to speak, the best stock. Homer Johnson, the Fuel Administrator for Ohio, brought the suggestion to me (whether it originated with him or with the operators in Ohio, I can't say), about the Ohio pool. It is a terminal pool, as distinguished from a pool at the center. It is working out, so far as I can learn, well. It is only in the early days of its organization.

Mr. Findley: I wondered whether a manufacturer who had a partial supply of fuel for his gas producers, for example, and for his byproduct too, and ordinarily bought a supply of coal in the market, whether his own supply of coal would go into a pool supply in case there was a pooling, or whether the pooling of the coal would be a pooling of the merchant supply, or whether the mine or his company would have to throw supply of coal into the pool.

Dr. Garfield: The whole supply would go from the shipper; that is, the operator, the mine would go into the pool.

Mr. Findley: If you were a producing consumer of coal your own coal would go into the general pool and you would only get perhaps a part of the coal that you yourself produced; that is, your normal supply might be reduced?

Dr. Garfield: I am not informed whether those who are producing coal entirely, exclusively for their own use, have consented to go into the pool or not. Perhaps Mr. Morrow, knows. Have you any such, Mr. Morrow, in the pool?

Mr. Morrow: I can't answer that specifically, but the point of his question, so far as it relates to byproduct coal, may be answered in this way: Byproduct coal needed in any plant will not be moved. That coal ordinarily moves in solid trainloads, and will not be interfered with. That refers to companies who have their own mines. They are not included in the pools now, but later on may be included.

W. C. Baker: Mr. Morrow in his address to us emphasized the effect of car shortage in reducing the output of the mines, and the question was being discussed as you came in, to what extent various causes were operating to produce that car shortage. I'd like to inquire to what extent there is congestion in the tidewater and other important terminals. Is it not a fact that a large amount of freight is tied up in the terminal yards and makes it very difficult to have coal cars promptly and ties them up too long a time in their shipment, so that they are slower getting back to the mine?

Dr. Garfield: Undoubtedly that contributes to it. When a crowd of vehicles and cars are tied up at a street corner, it is difficult to determine which car or vehicle is producing the trouble—they are all producing it. And yet, it is true that the congestion at the terminals is one large contributing factor, perhaps the largest of any.

Mr. Taylor: To what extent does the authority of the Fuel Administration extend in ordering a mine to ship coal to the transportation company?

Dr. Garfield: I think it extends a good deal further than some other. The reading of the act is that the Fuel Administration has control of the apportionment and shipping of coal—I haven't hesitated, therefore, but another section states that all the agencies of the Government shall perform such service as the Fuel Administrator may require of them. If the railroads were controlled by the Government, the task would be simple, I could then issue the order. Railroads being in private hands, I can ask for priority orders and make requests of them, but I haven't any power to force the railroads to do a thing asked for.

M. C. Robbins: Mr. Morrow expressed the opinion that the reason for the coal shortage is the lack of cars by the railroads. You mentioned an important reason for the coal shortage: the demand for 50,000,000 tons of coal to be produced. From other sources, it has been said that the fixing of the low price for bituminous coal has discouraged the output of a great many mines. I'd like to ask if all three of these things are the cause, or if there is any difference in importance in these three things.

Dr. Garfield: Undoubtedly the fixing of a lower price than the operators had hoped would be fixed, played its part, and yet I can't prove it. It looks as if the proof went the other way. The President's order went out on Aug. 21, and the second order on Aug. 23. The reports of production for the weeks beginning with, I think, the 18th and straight along for the next few weeks, increased each week; there was a larger production each week than the preceding week, and a larger production than the year before. So it is difficult to say that the appearance of the President's order fixing the price halted production. In fact, only in one week since the President's order has come out, was there a drop that was materially below the production of last year, and the average is considerably above.

Mr. Frost: I am in some way connected with the public schools of our city. Tomorrow we have to determine whether or not we shall declare a vacation for the winter for the purpose of conserving coal. I'd like to know what Dr. Garfield's opinion is on that important matter.

Dr. Garfield: My judgment about that is that it is very poor economy, unless we are actually forced to do it, in a community to shut down schools.

R. Sherman: Can you tell us anything about how much coal is saved by cutting out electric illumination at night?

Dr. Garfield: I wish I could give you accurate figures. I am disappointed in the results. I think the result was less productive of saving than we expected it would be, and I shall change the order; but I don't propose by any means to give up the idea of saving in the United States on signs and white ways. We want to interfere less with business and accomplish better results.

Mr. Baldwin: Dr. Garfield, I'd like to present this matter, where an industry depends upon its own power for this service, but has difficulty in obtaining its coal, and the proposition is made by the public service corporation for shutting down its plant; are the chances better for the company to unite with the public-service corporation engaged in furnishing electricity for power than to depend upon the Fuel Administrator for the necessary coal to keep the plant running, when, as a matter of fact, this same coal could be burnt in either instance?

Dr. Garfield: I doubt if one could answer that clearly, except in a specific case. I should say, nevertheless, attempting to answer it generally, that there is more economy in working through public utilities; but if, on the other hand, your public utility is already overloaded, obviously you have got to resort to some other way. If your public utility is so located that it has peculiar difficulty in getting its coal supply, one would answer the question otherwise, so that while I would answer it in that way in general, I would have to recognize the existence of several exceptions.

Mr. Tipples: I'd like to ask if the price had been higher and production at the mines greater, would it be of any value, under present conditions, or are we producing all the coal that we can handle?

Dr. Garfield: That question is a very pertinent one, because it is obviously true that if the roads are now clogged and can't deliver what we have on the rail, how much worse position would they have been in if we had produced more coal from the mines. I think that the transportation system of the country, as it stands today, is not able to take care of more than is now being produced. I think it may be possible to transport more under the arrangements which are now in the making.

Mr. Stone: Is a comprehensive plan in the making providing a release of ocean tugs for coastwise and Lake traffic to meet conditions next fall and winter?

Dr. Garfield: Yes, it is.

Mr. Black: To what extent have the public-service commissions been willing to coöperate with plans of your department in regard to the economy suggested by you for public utilities?

Dr. Garfield: No sufficient return has been received yet to answer that. So far as I know, there is no disposition to do other than coöperate.

Mr. Lockwood: Has anything been done to increase the production of power for industries by use of water power?

Dr. Garfield: No efforts are being put forth to introduce any substitutions of that kind, because they won't meet with the present emergency. Where there are hydro-electric operations, however, the request, of course, is that they depend as far as possible upon the water power, and indeed they would do it without our asking, because it is a cheaper way. There are many good plans of various kinds that could be introduced if we had time to introduce them. I want to say in that connection that report came to me last week that a good many of the hydro-electric operations in the country (this person happened to have come from the South) have stocked up with more coal than they need under the circumstances, so I suspect that that is one of the places where coal has been taken on in larger quantities than it need be.

A. I. Findley: Do you consider the coal shortage more difficult than the fuel-oil shortage just now, whether you are considering substituting fuel oil for coal in industry.

Dr. Garfield: I should say that fuel oil is in the long run less serious; the coal is more serious because it happens that our large munitions factories are depending upon coal, not for fuel oil—that is, in larger proportion.

Essex Power Plant Shut Down

At 5:30 Wednesday morning, Dec. 19, one of the instrument potential transformers on one of the 25,000-kv.-a. units (No. 1 unit) in the Essex Power Plant of the Public Service Electric Co., Newark, N. J., broke down and caused a very destructive burnout of the generator cables between the machine and oil switch. Although the trouble amounted to practically a short-circuit of the generator terminals, the unit was not injured. Nevertheless, the nature of the burnout made it impossible to get the machine back into service.

At the time of the trouble the two 25,000-kv.-a. units, which are at present installed in this station, were in service and carrying a load of 36,000 kv.-a. When No. 2 unit picked up the overload, its turbine developed a knock that was considered serious enough to shut the machine down so as to investigate the trouble rather than take a chance of more serious developments. This left the station dead and compelled the company to reduce its system's load by 25,000 kw., which could not be taken care of by the other plants on the system. By putting jumpers from No. 1 unit to the switches on No. 2, No. 1 machine was back into service by 2:30 in the afternoon, and by 4:30 the next day the trouble was cleared up and both machines back into service, which is a remarkably short time to make repairs of this magnitude.

When No. 2 turbine was opened, what appeared to have been a rub on one of the wheels was the only indication of what had caused the knock. This was remedied and the turbine put back into service without further developments.

The next morning after the accident at the Essex Plant, the company had to curtail its service for a short period at its Marion plant, owing to low steam pressure, on account of the heavy overload this plant was carrying during the peak period and the poor quality of coal that they have been forced to use.

The company, like many other central stations in this country, has all its spare capacity contracted for, in an endeavor to meet the heavy demands placed upon it by the many new industries that have grown up to supply the war needs of the nation. This, combined with the difficulties of obtaining deliveries of new equipment and an adequate coal supply, has brought about anything but an assuring condition in many cases.

At the present time a 35,000-kv.-a. unit is being installed at Essex and will be in service in a few weeks. This will give the company reserve capacity for some time to come and guarantee against a recurrence of the recent embarrassment.

Obituary

Charles J. Klein, designing engineer for the Cutler-Hammer Co., and a prominent electrical inventor, died suddenly at his home in Milwaukee, Wis., on Sunday night, Dec. 16. Mr. Klein was born in New York City 55 years ago and went to Milwaukee from the New York office of the Cutler-Hammer Co. in 1908. He was an intimate friend and co-worker of Thomas Edison for many years. He is survived by a son and a sister.

Frank Martin, well-known as an engineer and contributor to "Power," died on Christmas Eve of pneumonia after an illness of two weeks. As an operating engineer, Mr. Martin had a full experience. He was a master electrician in the United States Navy, having been stationed at the Brooklyn Navy Yard. For a number of years he was chief engineer of the Hard Rubber Co., College Point, N. Y., and served for a period as master mechanic of the American Thread Co., Willimantic, Conn. A few years ago Mr. Martin went to Honolulu as chief turbine engineer for the Marconi Wireless Telegraph Co. He returned to the United States about two years ago, after which he took a needed rest. At the time of his death he was first assistant chief engineer for the New York Steam Co. He also held the rank of chief machinist's mate in the Naval Militia when he died. Mr. Martin was an honorary member of Brooklyn No. 8, N. A. S. E., and a Master Mason, Oceanic Lodge, Honolulu. He is survived by his wife. Death came while Mr. Martin was in the New York Hospital. Services were held Friday, Dec. 28, at Stephen Merritt Chapel, Eighth Ave., New York City.

Personals

W. R. Jennison has been appointed Southeastern representative of the Hoppes Manufacturing Co., of Springfield, Ohio. with offices at 407 Bisbee Building, Jacksonville, Florida.

Robert E. Dillon, who has been in charge of the steam-testing division of the standardizing and testing department of the Edison Electric Illuminating Co., of Boston, has been appointed assistant superintendent of the generating department.

Fred Greanoff, formerly assistant superintendent at the Duluth Boiler Works, has resigned to engage in a similar business of his own at Buffalo, N. Y. Before leaving, Mr. Greanoff was presented with a gold watch and chain and stickpin by the employees of the Duluth Boiler Works.

J. C. Bannister has been made a vice president of the Walworth Manufacturing Co., of Boston, Mass. He was successively foreman in the tapping department of the Haxton Steam Heater Co., at Kewanee, superintendent of the pipe-finishing mill and chief engineer; superintendent of the Kewanee Boiler Co. and later manager of the Kewanee works.

D. J. Angus, who recently purchased an interest in, and associated himself with, the Esterline Co., of Indianapolis, Ind., as treasurer, has taken over the responsibility of the engineering department and of the design and development of new lines of instruments and apparatus. Prior to his connection with the Esterline Co., he was associated with J. W. Esterline in consulting-engineering work.

C. H. Andrews, assistant to president and chief engineer of the North Carolina Public Service Co., Greensboro, N. C., has been appointed general superintendent of the Southern Utilities Co., which corporation operates electric, gas and ice properties throughout Florida, under the management of the J. G. White Management Corporation, New York City. He will assume his new duties on Jan. 1.

L. L. Hebberd, for the last four years associated with the consulting engineering firm of Vaughn & Meyer, of Milwaukee, Wis., in charge of the mechanical-engineering department, is now with the Consolidated Water Power and Paper Co. as mechanical engineer and superintendent of steam power. His headquarters at present are at the Interlake Pulp and Paper Co., an affiliated company, at Appleton, Wisconsin.

Engineering Affairs

The Society of Automotive Engineers will hold a meeting in New York on Jan. 10 and one in Chicago on Feb. 1. Four engineering authorities on aviation—Maj. Jesse G. Vincent, father of the Liberty engine; Col. Clarke, Capt. Howard Marmon and H. M. Crane—will handle that part of the subject at the New York meeting. The Chicago meeting, which will be held at the Hotel Sherman, will be devoted entirely to farm-tractor subjects, and the war dinner will be held the same evening at the New Morrison Hotel.

The Engineering Society of York, Penn., elected the following officers for the ensuing year at its recent annual meeting: President, James Rudisill; vice president, Chauncey D. Bond; secretary, M. Haller Frey; treasurer, Harold A. Russell; directors, George A. Jessop, Charles L. Berger and Howard J. Longenecker. The annual reports show that considerable progress has been made during the past year and there has been a considerable increase in the membership of the organization.

The Evening Students Association of the Polytechnic Institute, of Brooklyn, N. Y., held its third annual smoker on Saturday, Dec. 22, in the gymnasium of the institute. There were fully three hundred in attendance. Chairman Price, of the entertainment committee, outlined the purposes of the association. Prof. Charles A. Green, director, welcomed the audience in a brief speech. The entertainment included boxing, wrestling, tumbling and humorous addresses by John Rogers, Doctor Foy and Jack Armour, of "Power." Fred Bucholtz was the master of ceremonies. Refreshments were served.

The American Association of Engineers held a meeting at Washington on Dec. 14, the object being to form a coöperative movement to assist the Government to secure desirable and qualified technical engineers. Among those present were: Admiral F. R. Harris, Admiral Baird, Major Zimmerman, of the Engineers' Depot, and Major Harrison. Capt. D. S. Hays, of the U. S. Engineer Corps, described how the organization rose from a small beginning to its present size. The following were elected officers of the Washington Chapter: President, F. R. Weller; first vice president, A. S. Grossberg; second vice president, Harry Stevens; secretary, Capt. D. S Hays; treasurer, O. M. Sutherland. The association is a member of the Chamber of Commerce of the U. S. A., and is coöperating with all the chambers of commerce throughout the country.

The Society of Automotive Engineers will hold a special meeting on the afternoon and evening of Jan. 25. The afternoon session will be held at the society's headquarters, 29 West 39th St., New York, and the dinner and evening session will be held at the Automobile Club of America, 247 West 54th St. The afternoon session will be devoted to the consideration of engines for motor boats; one of the subjects will deal with the Diesel engine and the other with engine design for submarine chasers, etc. James Craig, of the Craig Engineering Co., will speak on "Developments and Improvements in the Diesel Engine in the United States." E. A. Riotte, of the Standard Motor Construction Co., will give an address on "Engineering Fundamentals in Low-Speed Engines for Motor Boats." In the evening Erwin Chase, engineer of the Submarine Boat Corporation, will speak on "Equipping Our Transports with Motor Boats." Henry R. Sutphen, of the Submarine Boat Corporation, will give a talk on standardization in boat construction. It is planned to have a special movie film prepared for the evening, showing submarine chasers, coast patrols and other boats which use the explosion-type engine.

Miscellaneous News

Ordnance Department Wants One Hundred Draftsmen to fill positions paying from $800 to $1800 per year. Civil-service examinations for these positions will be held in Chicago, Jan. 8, 9 and 10. Positions will be permanent. Applications should be filed with Milward Adams, Secretary Civilian Personnel Committee, Ordnance Department, offices State Council of Defense, Chicago, Illinois.

The Goulds Manufacturing Co., Seneca Falls, N. Y., has put into effect, beginning Jan. 1, 1918, a bonus system whereby all hourly, piecework and salaried employees rated at $40 a week or under, will receive quarterly a bonus of 10 per cent. on their total salary for the previous three months. This bonus is contingent upon a stipulated amount of time being put in at actual work during the year, and is aimed to encourage full-time work.

The Little Miami Light, Heat and Power Co., of Cincinnati, Ohio, has instituted condemnation proceedings under the right of eminent domain for rights for a $1,500,000 hydro-electric system in the Little Miami River district between Plainville and Morrow. It intends to build fifteen dams on the Little Miami River. There will be no lock system in connection with these, the only openings to be fish chutes. The corporation expects to develop 10,000 hp., which will be used outside of the City of Cincinnati proper. It also proposes to develop other territory bordering along the river, a distance of 30 miles.

The Woman's Committee for Engineer Soldiers has been formed in Washington, D. C. Mrs. William M. Black, wife of General Black, Chief of Engineers, is president; Mrs. Charles Keller, vice president and chairman; Mrs. W. W Harts, secretary; Mrs. Ulysses Grant, 3rd, treasurer. The object of the Woman's Committee is to see that no engineer soldier leaves this country without the proper knitted garments and to send garments to those already "over there." The National Committee in Washington is to be headquarters for units all over the country and by purchasing yarn in large wholesale quantities should be able to get better prices and deliveries. The dues are $1 a year, and a very earnest appeal is made to every man and woman interested in the engineers of the Regular Army, National Army, the Railroad, Forestry, Camouflage, or Labor regiments, to join this organization or to send contributions of money for wool or finished knitted garments, to supply these hundred thousand men. Address Mrs. William M. Black, 1730 I St., N.W., or Mrs. Ulysses Grant, 3rd, 2204 R St., N.W., Washington, D. C.

To Train 50,000 Men for New Ships—The "Gov. Dingley," a coastwise passenger steamer until recently in the Boston-Yarmouth, N. S., service, has been chartered by the United States Shipping Board Recruiting Service, of which Henry Howard is director, with national headquarters at the Boston Custom House, for a training ship for crews for the new merchant marine. She is the second training ship chartered here, the first one being the "Calvin Austin," which recently went to Halifax as a relief ship as her first mission for the Shipping Board Recruiting Service. Like the "Calvin Austin," the "Gov. Dingley" will have her base at the new Federal Wharf at East Boston. She will accommodate a "class" of 500 seamen, firemen, oilers, water tenders, cooks and stewards, who will be given intensive instruction by experts to fit them for places in the new merchant marine. The training of 50,000 men on training ships during the next year will be directed by the new Sea Training Bureau, with headquarters at the Boston Custom House, and with Capt. Eugene E. O'Donnell, supervising inspector, Fifth District, U. S. Steamboat Inspection Service, as supervisor. Capt. James P. Stevenson, until recently marine superintendent of the United States transport service, is executive head under Captain O'Donnell. Headquarters of Mr. Howard, at the Boston Custom House, are being flooded with applicants for enrollment on the new training ships.

Trade Catalogs

Esterline Graphic Efficiency Instruments. The Esterline Co., Indianapolis, Ind. Booklet No. 370. Pp. 12; 6 x 9 in.; illustrated.

Safety Switches and Cut-Outs. The Palmer Electric and Manufacturing Co., Boston, Mass. Bulletins M13 and M17; pp. 4; 6 x 9 in.; illustrated.

New Clutch Drive Rochester Automatic Lubricator. Greene, Tweed & Co., 109 Duane St., New York. Booklet showing different installations of this lubricator.

Class "Y-C-E" Duplex Direct Connected Electrically Driven Air Compressors. Nagle Corliss Engine Works, Erie, Penn. Bulletin No. 30. Pp. 12; 6 x 9 in.; illustrated.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Dec. 28, 1917	One Year Ago	Dec. 28, 1917	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7:35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Dec. 28, 1917	One Year Ago	Dec. 28, 1917	One Year Ago
Clearfields....	....	$3.00	....	$4.25—5.00
Cambrias and Somersets...	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Dec. 28, 1917	One Year Ago	Dec. 28, 1917	One Year Ago
Pea	$5.05	$4.00	$5.80	$5.50—5.60
Buckwheat ..	4.30—5.00	2.75	5.75—6.00	4.75—5.00
Rice	3.75—3.95	2.20	4.75—5.00	3.00—3.25
Barley	3.25—3.50	1.95	3.70—3.95	2.25—2.50
Boiler	3.50—3.75	2.20	4.00—4.50	....

Bituminous smithing coal, $4.50—5.25 f.o.b.

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)...........	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide		Independent
	Dec. 28, 1917	One Year Ago		Dec. 28, 1917	One Year Ago
Buckwheat ...	$3.15–3.75	$2.00	$3.75	$2.90	$4.15
Rice	2.65–3.65	1.25	3.65	2.15	3.35
Boiler	2.45–2.85	1.10	3.55	2.00	....
Barley	2.15–2.40	1.00	2.40	1.90	2.35
Pea	3.75	2.80	4.65	3.70	....
Culm	....	....	....	....	1.25

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.65—2.80	$3.10—3.25
Mine-run	2.40—2.55	2.85—3.00
Screenings	2.15—2.30	2.60—2.75

Smokeless Coals	So. Illinois, Pocahontas, Pennsylvania and West Virginia	Hocking, East Kentucky and West Virginia Splint
Prepared sizes	$2.60—2.80	$3.05—3.25
Mine-run	2.40—2.60	2.40—2.60
Screenings	2.10—2.30	2.10—2.30

St. Louis—Prices pet net ton f.o.b. mines a year ago as compared with today are as follows:

	Williamson and Franklin Counties		Mt. Olive and Staunton		Standard	
	Dec. 21, 1917	One Year Ago	Dec. 21, 1917	One Year Ago	Dec. 21, 1917	One Year Ago
6-in. lump..	$2.80	$3.00	$2.80	$2.60	$2.80	$2.25–2.50
2-in. lump..	2.80	....	2.80	....	2.80	2.00–2.25
Steam egg...	2.80	3.00	2.80	....	2.80	2.00–2.25

2-in. screen.	2.30	2.75	2.30	2.50	2.30	2.00–2.25
No. 5 washed	2.30	2.75	2.30	2.75	2.30	2.00–2.25

Williamson-Franklin rate St. Louis, 87½c.; other rates, 72½c.

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump and Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona....	2.15	2.40	1.90
Black Creek, Cahaba ...	2.40	2.65	2.15

Government figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

PROPOSED CONSTRUCTION

Ark., Marianna—The Citizens Service Co. has applied for permission to build an electric-lighting and power plant here.

Ky., Whitesburg—W. C. Daniels & Son are having plans prepared for the erection of a transmission line from here to Mayking.

Mo., Appleton—City plans election in January to vote on a $15,000 bond issue to improve its electric-lighting plant. W. B. Rollins & Co., 209 Railway Exch., Kansas City, Engrs.

N. J., Bloomfield—The Power Specialty Co., 111 Bway, New York City, has had plans prepared for the erection of a new plant on Locust Ave., here. Estimated cost, $31,000.

N. J., Jersey City—Swift & Co., Union Stock Yards, Chicago, has had plans prepared for the erection of a 50 x 50-ft. addition to its power house on 9th St., here.

N. J., Perth Amboy—City plans to extend its street-lighting system for which $25,000 has already been appropriated.

Ohio, Cleveland—The Municipal Electric Light Co. plans to improve its plant including the installation of new equipment involving a switchboard, generator, boilers and engines. About $700,000 will be expended. R. Hoffman, City Engr.

Ohio, Columbus—The Columbus Railway, Power and Light Co. has petitioned the Public Utilities Commisison for permission to issue $1,276,000 in capital stock and bonds; the proceeds will be used in additions and improvements in connection with its new plant. H. W. Clapp, Gen. Supt.

Ohio, Salineville—City voted $25,000 bond issue for the erection of an electric-lighting plant.

Okla., Commerce—The Triangle Mines Co. plans to install an electric-lighting and power plant. N. C. Barry, Pres.

Penn., Hazleton—The Harwood Electric Co. is having plans prepared for the erection of extensions to its plant.

Penn., Philadelphia—Wallace & Co. plans to build a 28 x 95-ft. power house on 81st St. and Island Rd. Estimated cost, $10,000.

Penn., Somerset—The Johnstown & Somerset Ry. plans to install new equipment in its 300-kw. substation. U. S. Houck, Supt.

Tex., Ft. Worth—The Fort Worth Power and Light Co. has increased its capital stock from $3,860,000 to $4,360,000 and plans to install new equipment in its power plant including a new 23,000-hp. steam turbine generator. A. H. Duncan, Mgr.

Va., Lynchburg—The Retail Merchants' Association plans to install an electric-lighting plant.

Va., Petersburg—The Petersburg & Appomattox Electric R.R., Sycamore St., is having plans prepared by F. A. Bishop, Arch., for the erection of a 1-story central heating plant at Lakemont, near here. J. A. Baird, Supt.

Wash., Everett—City is having plans prepared by Burn & McDonnell, Engrs., 400 Inter-State Bldg., Kansas City, Mo., for the erection of a power plant. Estimated cost, $800,000. Noted Oct. 2.

Wash., Kalama—The Kalama Lumber and Shingle Co. plans to improve its plant, including the installation of a new boiler plant and other machinery.

Wash., Puget Sound—(Bremerton P. O.)—(Official)—Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard, Puget Sound, under Schedule No. 1638; 1000 ft. rubber-insulated interior communcation cable; 1000 ft. lighting and power wire; 10,000 ft. single-conductor lighting and power wire; 5000 ft. two-conductor lighting and power wire.

Wash., Seattle—Skinner & Eddy, 150 Massachusetts St., has been granted a permit to erect a power plant. Estimated cost, $3000.

Wash., Shelton—The Shelton Light and Power Co. has petitioned the County Commissioners for a franchise to build and operate a transmission line from its plant at Goldsborough Creek over the county roads.

W. Va., Fairmont—The Greater Fairmont Investment Co. is considering plans for the erection of a 10,000-kw. generating station.

Wis., De Pere—The Western Manufacturing Co. of De Pere plans to build a boiler house. Estimated cost, $45,000.

Wis., Gresham—City plans to install an electric-lighting plant and water-works system.

Wis., Janesville—The Janesville Electric Co. plans to build an addition to its power house.

Wis., Madison—City is having plans prepared for the erection of a substation on Sprague St., in the Wingra Sewer District. E. E. Parker, City Engr.

Prices—Materials and Supplies

These are prices to the power plant by jobbers in the larger buying centers east of the Mississippi. Elsewhere the prices will be modified by increased freight charges and by local conditions.

ELECTRICAL SUPPLIES

KNIFE SWITCHES—Following are net prices each in cities named for knife switches mounted on slate base, front connected, punched clip type, 250 volts:

	30 Amp.	60 Amp.	100 Amp.	200 Amp
D. P. S. T. fuseless	$0.52	$0.93	$1.90	$3.42
D. P. S. T. fused	.81	1.37	2.70	5.14
D. P. D. T. fuseless	.88	1.52	3.42	5.70
D. P. D. T. fused	1.67	2.58	5.62	9.88
T. P. S. T. fuseless	.78	1.40	2.86	5.14
T. P. S. T .fused	1.22	2.05	4.18	7.70
T. P. D. T. fuseless	1.37	2.35	5.24	8.82
T. P. D. T. fused	2.68	4.13	8.99	15.80

Lots $25 and more, list.

FUSES—Following are net prices of 250-volt inclosed fuses each, in standard packages, in cities named:

0-30 amperes	$0.11¼ each	110-200 amperes	$0.90 each
31-60 amperes	.15¾ each	225-400 amperes	1.62 each
61-100 amperes	.40 each		

FUSE PLUGS (MICA CAP) PER 100

0-30 amperes.. 4c. each in standard package quantities (500)
0.30 amperes.. 5c. each for less than standard package quantities (500)

SOCKETS, B. B. FINISH—Following are net prices in cents each in standard packages:

1- to 5-lb. cans	13.25	13.00	12.50	12.50	13.00	12.50

RIVETS—The following quotations are allowed for fair-sized orders from warehouse:

	New York	Cleveland	Chicago
Steel ⅞ and smaller	30%	30%	40%*
Tinned	30%	30%	40%*

*For less than keg lots the discount is 35%.

Button heads, ¾, ⅞, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:

New York ..... $7.00 Cleveland ..... $6.85 Chicago $5.50

Coneheads, same sizes:

New York ..... $7.10 Cleveland ..... $6.95 Chicago $5.60

AMMONIA—Below are prices per lb. in cities named:

	New York	Chicago	St. Louis
26-deg. U.S.P. carboys of 100 lb.	16c.	12c.	....
26-deg. U.S.P. drums of 1000 lb.	14c.	10c.	12c.

Anhydrous ammonia in 100-lb. cylinders costs 30c. per lb. in St Louis, Chicago and New York.

FIRE BRICK—Quotations on the different kinds in the cities named are as follows, f.o.b. works:

	New York	Chicago
Silica brick, per 1000	$50.00 to 55.00	$50.00
Fire clay brick, per 1000, No. 1	45.00 to 55.00	....
Magnesite brick, per net ton	135.00 to 145.00	....
Chrome brick, per net ton	135.00	....
Deadburned magnesite brick, per net ton	85.00 to 90.00	....
Special furnace chrome brick, per net ton	60.00 to 70.00	60.00 to 80.00

Standard size fire brick, 9 x 4½ x 2½ in. The second quality is $4 to $5 cheaper per 1000.

St. Louis—High grade, $55 to $65; St. Louis grade, $40 to $50.
Birmingham—Fire clay, $25 to $30; Denver, $23, per 1000.
Chicago—Second quality, $25 per ton.

FUEL OIL—Price variable, depending upon stock. New York quotations not available owing to this fact. In Chicago and St Louis the following prices are quoted:

	Chicago	St. Louis
Domestic light, 22-26 Baumé	5¼c.	4½–4¾c.
Mexican heavy, 12-14 Baumé	7c.	

Note—There is practically no fuel oil in Chicago at present time.

SWEDISH (NORWAY) IRON—The average price per 100 lb., in ton lots, is:

	Dec. 28, 1917	One Year Ago
New York	$15.00	$7.50
Cleveland	15.30	7.50
Chicago	15.00	5.75

In coils an advance of 50c. usually is charged.
Note—Stock very scarce generally.

POLES—Prices on Western red cedar poles:

	New York	Chicago	St Louis	Denver
6 in. by 30 ft	$5.59	$4.94	$4.94	$4.3[illegible]
7 in. by 30 ft	7.40	6.60	6.60	5.80
7 in. by 35 ft	10.70	9.60	9.60	8.55
8 in. by 35 ft	12.20	10.90	10.90	9.65
7 in. by 40 ft	12.35	11.00	11.00	9.75
8 in. by 40 ft	13.75	12.15	12.15	10.65
8 in. by 45 ft	18.20	16.20	16.20	14.30
8 in. by 50 ft	21.85	19.45	19.45	17.15

10c. higher freight rates on account of double loads.

For plain pine poles, delivered New York, the price is as follows:

10-in. butts, 5-in. tops, length 20-30 ft.	$6.00
12-in. butts, 6-in. tops, length 30-40 ft.	8.50
12-in. butts, 6-in. tops, length 41-50 ft.	9.50
14-in. butts, 6-in. tops, length 51-60 ft.	17.00
14-in. butts, 6-in. tops, length 61-71 ft.	18.50

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Nov. 6, 1917, for steel pipe and for iron pipe:

Steel			Iron		
Inches	Black	Galvanized	Inches	Black	Galvanized
BUTT WELD					
⅛, ¼ and ⅜	44%	17%	¾ to 1½	33%	17%
½	48%	33½%			
¾ to 3	51%	37½%			
LAP WELD					
2	44%	31½%	2	26%	12%
2½ to 6	47%	34½%	2½ to 4	28%	15%
			4½ to 6	28%	15%
BUTT WELD, EXTRA STRONG PLAIN ENDS					
⅛, ¼ and ⅜	40%	22½%	¾ to 1½	33%	18%
½	45%	36½%			
¾ to 1½	49%	36½%			
LAP WELD, EXTRA STRONG PLAIN ENDS					
2	42%	30½%	2	27%	14%
2½ to 4	45%	33½%	2½ to 4	29%	17%
4½ to 6	44%	22½%	4½ to 6	28%	16%

Note—National Tube Co. quotes on basing card dated Apr. 1.

From warehouses at the places named the following discounts hold for steel pipe:

	Black		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	38%	42.8%	40.1%
3½ to 6 in. lap welded	18%	38.8%	36.1%

	Galvanized		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	22%	27.8%	25.1%
3½ to 6 in. butt welded	List	24.8%	22.1%

Malleable fittings, Class B and C, from New York stock sell at list price. Cast iron, standard sizes, 15 and 5%.

BOILER TUBES—The following are the prices for carload lots f.o.b. Pittsburgh, announced Nov. 13, as agreed upon by manufacturers and the Government:

Lap Welded Steel		Charcoal Iron	
3½ to 4½ in.	34	3½ to 4½ in.	12½
2½ to 3¼ in.	24	3 to 3¼ in.	+ 5
2¼ in.	17½	2½ to 2¾ in.	+ 7½
1¾ to 2 in.	13	2 to 2¼ in.	+22½
		1¾ to 1⅞ in.	+35

Standard Commercial Seamless—Cold drawn or hot rolled:

	Per Net Ton		Per Net Ton
1 in.	$340	1¾ in.	$220
1¼ in.	280	2 to 2½ in.	190
1⅜ in.	270	2¾ to 3¾ in.	180
1½ in.	220	4 in.	200
		4½ to 5 in.	220

These prices do not apply to special specifications for locomotive tubes nor to special specifications for tubes for the Navy Department, which will be subject to special negotiation.

POWER

Vol. 47 NEW YORK, JANUARY 8, 1918 No. 2

HELPFUL HINTS

Team Work in the Plant

The tendency toward specialization has penetrated the power plant no less than every other establishment devoted to productive service. As organizations are perfected, the duties of individuals are often restricted as to responsibility, and where this policy is carried to extremes, men are sometimes tempted to lose interest in each other's work. The larger efficiency of the service suffers accordingly, and can only be restored by team play. Upon the personality of the chief engineer much depends in this connection.

No plant can be organized solely like a machine and achieve the best results. Conditions are different from those in the mill or shop, where a tangible product is passed rapidly through the establishment, seen of men as it goes from step to step, ponderable and real. We cannot operate a power plant on the piecework basis. Between certain periods a measure of relief comes to the staff on duty; at other times the pressure rises and puts a heavy strain on part of the force. When these strains are noncoincident a little extra help may accomplish wonders.

Just because a fire wall separates the engine and boiler rooms shall the men on either side of the brickwork assume that they have little in common? There is no more reason for insularity here than for hostility between engineer and fireman on the locomotive or for cross-purposes between the army and the navy.

If a turbine breaks down at a critical period of the load, necessitating the immediate attention of the turbine-room force, and additional assistance is needed from the fireroom, no matter for what purpose, let it be cheerfully rendered. "I wasn't hired to do this!" is one of the most miserable points of view that a human being can take in facing an emergency call on his services. It is as good a recipe for staying in the mediocre class as can be quoted, and puts a man in a group of which he should be ashamed to be a member.

Diametrically opposed to this attitude is the cooperative spirit shown by the chief when, in a critical time, he strips off his coat and vest and "mobilizes" every ounce of ability and strength he possesses at the scene of trouble; of the construction superintendent who doesn't hesitate to go into a manhole with a dress suit on in order to clear up trouble for which he is ultimately responsible and which is costing his company a month's salary every hour that service is interrupted; and of the assistant engineer who doesn't balk at coal passing for a quarter-hour in case the regular force is overloaded through the sudden illness of one of its members on the job.

The operating records and the atmosphere of friendly collective effort in many plants bear witness to the team work therein. Much of this cooperation never gets into the log sheet and is known to only two or three men most immediately affected. It counts on the unit costs, however; and important as it is to define the responsibilities of individuals, it is wise not to attempt to limit their range of mutual helpfulness.

The smaller the station, the more give and take there naturally is between the operating men on duty; but even in the larger plants there is room for the practice of a personal "readiness-to-serve," which goes a long way toward maintaining good records in station performance.

Operation and Maintenance of Elevators—Winding-Drum Machines

By R. H. WHITEHEAD

The various parts of a modern winding-drum-type elevator machine and their function are described. Two classes of machines are considered; namely, those located overhead and those installed in the basement or on a lower floor.

A COMPLETE installation, using the winding-drum type of elevator machine, is shown in Figs. 1 and 2. In Fig. 1 the machine is set on overhead beams at the top of the hoistway; in Fig. 2 on a concrete foundation in the basement or lower floor. The particular feature that characterizes this type of installation is the spirally grooved drum *D* which winds or unwinds the ropes to the car *C* and to the drum counterweight *DW*. When raising the car, the car ropes are wound up on the drum and at the same time the ropes to the drum counterweight unwind, thus lowering the latter. In this manner the weight of the car and the load in the car are partly counterbalanced by the drum counterweight.

Besides the foregoing method of counterbalancing, in some cases, as in the illustrations, a car counterweight *CW* is provided, the ropes for which lead directly from the car to an overhead sheave *S* or sheaves, as the case may be, and thence to this separate counterweight. This, of course, takes a certain amount of load from the car ropes leading to the drum and thereby makes it possible to handle a heavier load than would be the case otherwise. The amount of counterbalancing and its distribution between the car counterweight and the drum counterweight depend on the speed, load and service of the elevator. The counterweights are carefully adjusted by the elevator manufacturers to secure the most economical results for the particular condition, when the installation is first made. However, the car counterweight under any condition must be less than the weight of the empty car, and the total amount of counterweight is generally equal to the weight of the car plus 25 to 40 per cent. of the speed load.

Arrangement of Counterweights

As shown in Figs. 1 and 2, the car counterweights and drum counterweights both run in the same set of hoistway guide rails *HG*. They are entirely independent, however, the weights for each being contained in separate frames. It is necessary to slot or recess the weights in the top or car-counterweight frame so as to permit the passage of the ropes to the bottom or drum-counterweight frame and to slot the ends of the top and bottom frame weights in each frame to engage the guide rails. The drum counterweights are placed in the bottom frames and the car counterweights in the top, and the ropes are adjusted so that the frames are about six inches apart. This arrangement is necessary in order to prevent the addition of the drum counterweight to the car counterweight in the event of the possible breaking of the drum-counterweight ropes, as under this condition the car with a light load would be seriously overbalanced.

Where the drum-counterweight ropes pass through the car counterweight, they are inclosed in steel tubes to prevent abrasion as there is a small difference in the relative movement of the two sets of counterweights when starting and stopping the car. An adjustment of the rope lengths should always be maintained so that the weights bottom before the car strikes the overhead work and so that the car fully compresses the spring bumpers *B* shown in the pit at the bottom of the hatchway, Fig. 1, before the counterweights come in contact with the overhead work. Allowances should be made for a sufficient margin of overtravel to take care of the inertia of the machine and weights.

Counterweight Compensation

In Fig. 1 a chain *H* is shown attached to the bottom of the car and the drum-counterweight frame. As the car rises in the hoistway, the ropes to the overhead work become shorter and the ropes from the overhead work to the weights become longer, with the result that the weight of the ropes on the car side becomes less and increases on the counterweight side. This produces a constantly changing amount of counterbalance for which it may be advisable to provide compensation. Where the rise is less than 150 ft., the unbalancing of the ropes makes little difference, but for higher rises it is advisable to provide a chain counterbalance, as shown in the figure, which neutralizes this shifting of the rope weight and keeps the counterbalance constant, thus saving in the power consumption of the elevator. Where chain counterbalance is provided, the links of the chain are generally interwoven with sash cord to eliminate noise.

The elevator cab shown is set in a steel frame or "sling." This sling consists of top channels *F* forming a crosshead, two bottom channels forming the safety plank *P*, upright channels *U*, called stiles, connecting the crosshead and safety plank with a platform mounted on the latter and braced to the stiles with tension braces *TB*. Gusset-plate bracing *G* is shown between the crosshead and stiles. The car and car-counterweight ropes connect by thimbles to the center of the crosshead. At the ends of the crosshead channels and safety plank are the adjustable-spring guide shoes *A*, which are slotted and fitted with gibs to engage the main guide rails *M* in the hoistway. The guide shoes are each attached to a stem inserted in a holder and held by a bracket on the crosshead and safety plank. The shoes are arranged so as to have limited movement, backed by spring pressure which keeps them securely against the rails.

Figs. 1 and 2 both show a ball governor *E* located overhead. The rope operating this governor passes around a tension sheave *N* at the bottom of the hoistway, Fig. 2, and is connected to a device *J* on the car that actuates the safety. If the car overspeeds when moving in a downward direction, as would occur if the

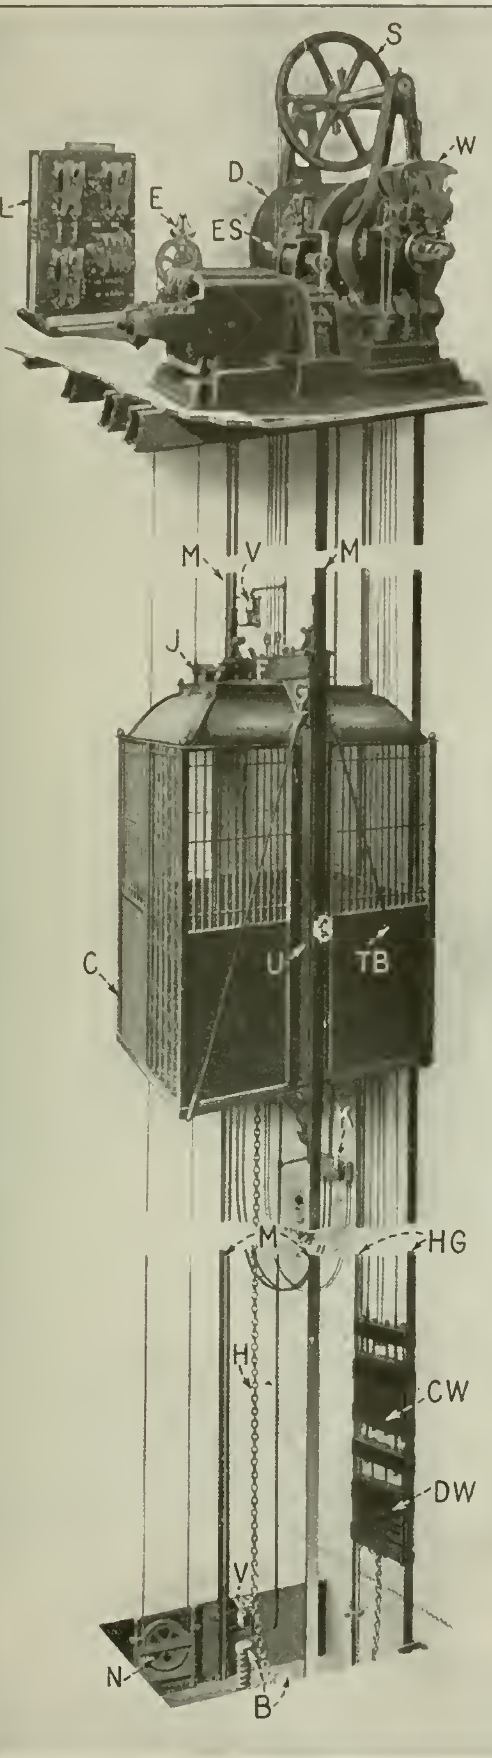

FIG. 1. WINDING-DRUM-TYPE ELEVATOR MACHINE; OVERHEAD INSTALLATION

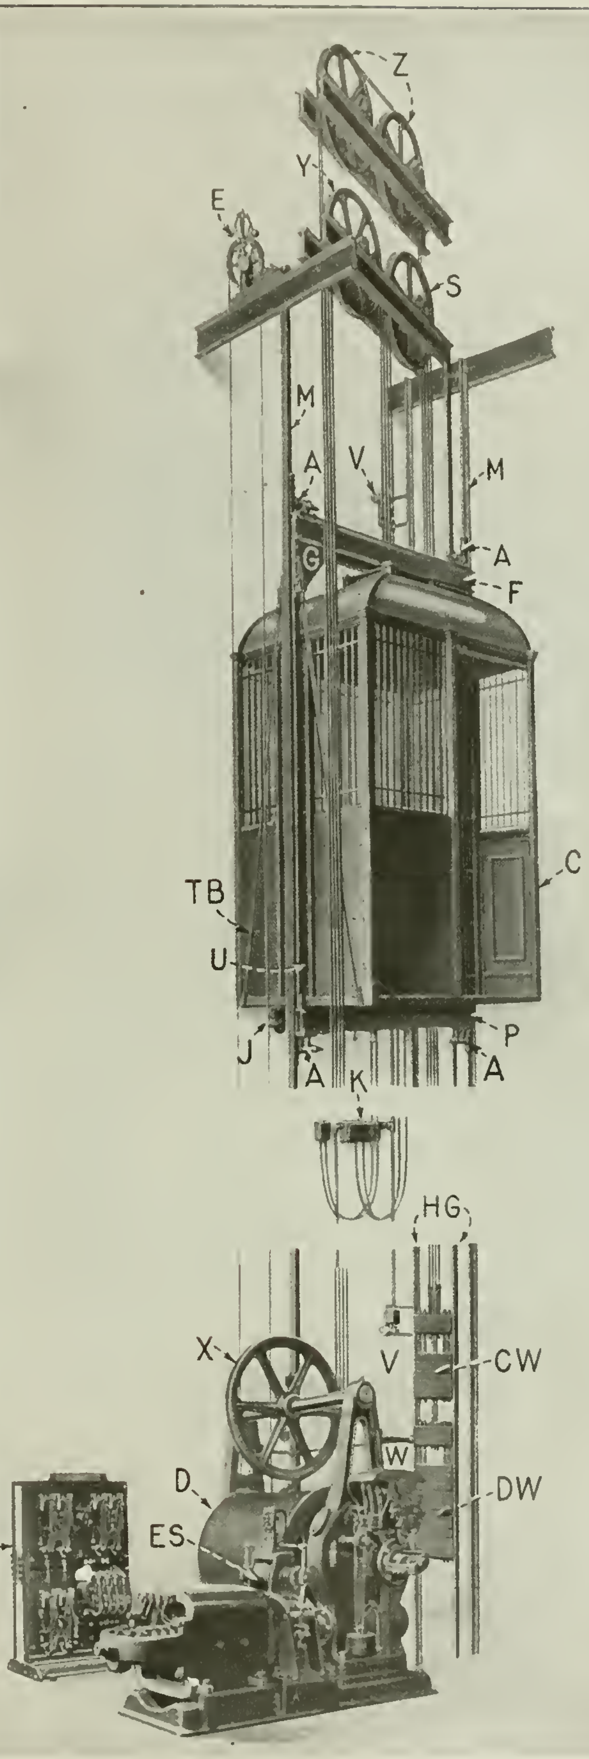

FIG. 2. WINDING-DRUM-TYPE ELEVATOR MACHINE; BASEMENT INSTALLATION

car ropes parted, the balls on the governor spread sufficiently to throw the governor jaws and hold the governor rope fast. This operation sets the car safety gripping device against the main guide rails and stops the car. A later article will describe in detail the various types of safeties and their operation.

Each of the installations shown in Figs. 1 and 2 is of the car-switch-control, single-speed type. The flexible cables containing the wires of the control circuits lead from the bottom of the car to the junction boxes *K* in the hoistway and are used for the operation of the controller by the car switch, for the light in the car and for the floor-signal system. The controllers *L* shown are arranged for direct current. Later articles will deal with various types of both alternating- and direct-current elevator controllers. In the present case each controller has a main-line or potential switch, "up" and "down" direction switches and an accelerating switch which brings the motor automatically up to full speed at a rate depending upon the load. A movement of the car-controlling switch toward the car-door opening energizes the magnet of the down-direction switch. This magnet closes the switch, which simultaneously lifts the brake shoes and connects the motor to the line so that it rotates in the proper direction to lower the car. Similarly, a movement of the car switch away from the door opening energizes the magnet of the up-direction switch. In the car a safety switch is provided which, when opened in case of emergency, interrupts the circuit of the potential-switch magnet, and this in turn interrupts the current to the direction switches and stops the car.

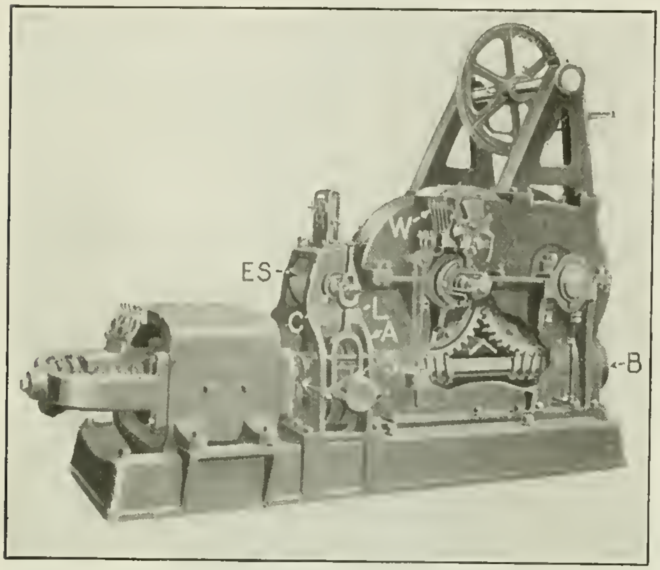

FIG. 3. DOUBLE-SCREW ELEVATOR MACHINE

Hoistway limit switches *V* are provided at the top and bottom of the hoistway. A cam mounted on the side of the car engages these limit switches after the car overruns the top- or bottom-terminal landing. This also causes the potential switch on the controller to open. A slack-rope switch is provided which opens the potential switch when the hoisting ropes become slack for any reason. In the case of an overhead machine this switch is mounted on the car crosshead and connected to the car ropes. For a machine in the basement or on the lower floor, the slack-rope switch is located on the bedplate under the hoisting drum. In either case, when the ropes become slack, as they would when the car safety operates or when the car runs down onto the bumpers in the pit, the amount of slack is prevented from increasing by stopping the motor. The slack must be removed and the ropes properly placed on the drum before the car is again started.

The hoisting machines are provided with an automatic switch *W*, shown in the figures on the right-hand side of each machine. This switch is adjustable and is set so that the car will run only a short distance past the top and bottom landings, if the elevator operator neglects to center the car-controlling switch. The automatic switch first causes the direction switch on the controller to open, corresponding to the direction of car travel, and the brake to set; a further movement of the car opens the hoistway limit switch *V*, and a still further movement causes the automatic switch *W* to open the main-line circuit to the motor.

It will be noticed that each machine has attached a sheave, *S* Fig. 1 and *X* Fig. 2, arranged to move along a shaft parallel with the drum. This sheave is known as an "attached vibrator," the sheave moving or vibrating back and forth along the shaft so as to maintain a proper lead on the ropes as they wind or unwind on the drum. Frequently, vibrator sheaves and shafts are detached from the machines and they are then termed "detached vibrators." In the case of a machine located in the basement or lower floors, as in Fig. 2, the attached vibrator is used for the drum-counterweight ropes and the vibrator sheave must move along the shaft as the ropes wind and unwind on the drum. For machines located overhead, as in Fig. 1, the attached vibrator is used for the car-counterweight ropes and does not move along the shaft although it is still called an "attached vibrator." Frequently two or three vibrator sheaves rotate on the same shaft, depending on the particular characteristics of the layout.

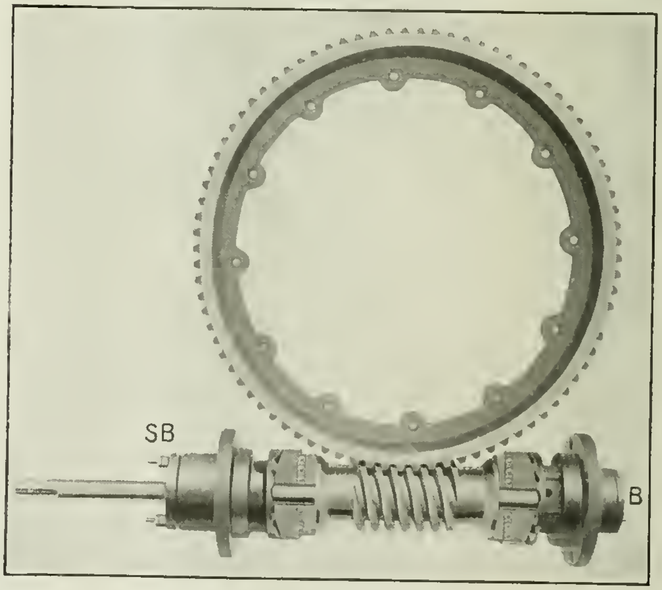

FIG. 4. SINGLE WORM AND GEAR, SHOWING BALL-THRUST BEARINGS

The sheaves shown overhead in Fig. 2 are termed the "overhead sheaves." Where there are two in the same horizontal plane for one set of ropes, as shown at *Z*, they are called "tandem sheaves." Sheaves *Z*, Fig. 2.

are used for the drum-counterweight ropes and sheave *Y* for the car-hoisting ropes.

The drum and worm-wheel spiders of the machine are keyed to the drum shaft. This shaft is provided with marine or collared bearings mounted in the outboard-end stand and in the wormwheel casing. This type of bearing is required so as to resist the side thrust of the wormwheel. The worm shaft is provided with an outboard bearing *B* in the gear case and passes through a stuffing-box *SB* on the inboard bearing of the case, Figs. 3 and 4. The motor shaft and worm shaft are connected with a coupling which is also used for the brake drum. The brake *A*, Fig. 3, is operated with an electric solenoid *ES* which, when energized, pulls the solenoid cores together. The cores *C* are attached to a link motion *L*, which lifts the brake shoes off the brake drum, the lifting being opposed by springs at *S*. When the circuit of the solenoid is open, these springs apply the shoes to the brake drum, and if properly adjusted, the car is smoothly brought to rest at all loads. This stopping distance is called the slide and varies with the car speed and load.

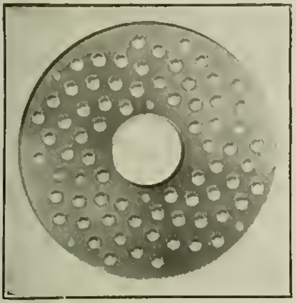

FIG. 5. THRUST-BEARING BALL PLATE

The outboard drum-bearing stand, gear case, brake stand and motor are all bolted to a cast-iron bedplate. This bedplate must be rigidly supported in place and the alignment of the motor shaft and worm shaft carefully checked after the load of the car and counterweight are on the drum before coupling them together.

Drum-winding machines are either of the single-screw type, shown in Figs. 1 and 2, or the double-screw type, as shown in Fig. 3. In the single-screw type, the thrust between the worm and wheel is taken on a ball thrust bearing. The details of the worm and wheel, thrust and worm shaft bearings are clearly shown in Fig. 4. Fig. 5 shows a thrust-bearing ball plate; note the spiral arrangement of the balls to evenly distribute the wear. In the double-screw type of machine, Fig. 3, no thrust bearings for the worm shaft are required as a right and a left worm on the same shaft as part of the same forging engage a right and a left wormwheel, which in turn are also cut to mesh together as spiral gears, thus giving a three-point drive. The outboard wormwheel is attached to the drum shaft. The worms may be single, double or triple threaded in either single- or double-screw machines, depending on the car speed desired.

Ventilated Side Walls

By William R. Caton

One source of annoyance to all stoker operators is the tendency of clinkers to stick to the side-walls, cutting down the available grate area and badly injuring the brick when cleaning fires. By the constant breaking away of brick that are melted into clinkers, the side-walls need frequent repairs. After a number of years of repairing brickwork in furnaces, Ernest Bernitz tried the method of ventilating the side- and bridge-walls shown in the accompanying illustrations.

Fig. 1 shows the furnace walls with Riley stoker. A hole five or six inches square is built in the wall below the grate and connecting air chamber under the grate with the 1½- or 2-in. pocket built in the side-wall. Above the grates for three, four or five courses, depending on what capacity boiler is to be worked, headers are laid without fireclay between side joints, which allows air from the air chamber to go to the side-wall pocket, then through the narrow apertures between the brick, keeping the brick cool and preventing clinker sticking to them. Fig. 2 shows the side-wall built with Taylor stokers. The brickwork or setting with Taylor stoker is similar to that with the Riley, but to connect it for ventilation necessitates cutting a V-shaped hole through the cast-iron wind-box under the tuyere irons.

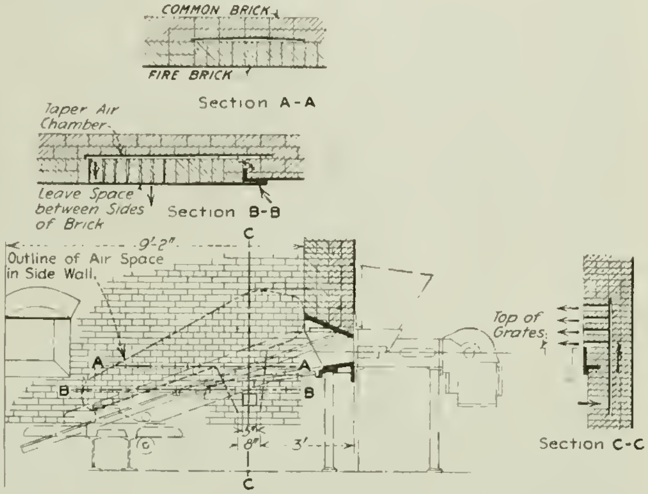

FIG. 1. SIDE-WALL AIR OPENINGS, RILEY STOKERS

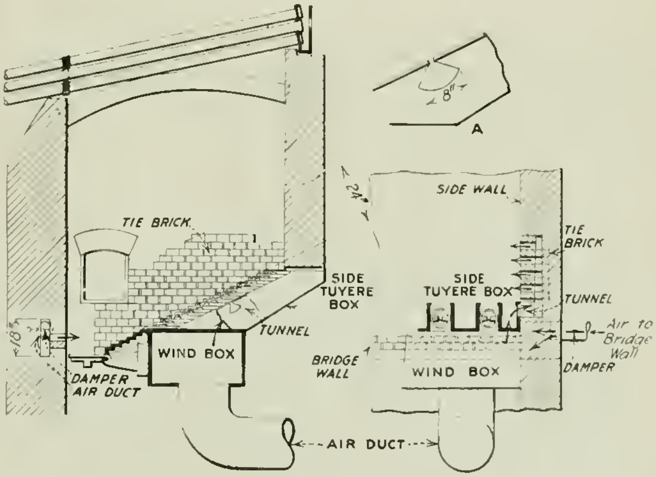

FIG. 2. SIDE-WALL AIR OPENINGS AS APPLIED TO TAYLOR STOKER

This scheme of ventilating was tried with hand fires and natural draft many years ago, but never proved successful enough to warrant a patent on it. With forced draft it is a success, either with stokers or hand fires.

Delivery of equipment these days is as slow as that lack of speed expressed by the English cabby to his American charge who protested at the cockney's delay. "'S all right; you kept us waitin' three years."

Camp Dix Military Cantonment

THE photographs reproduced show in a general way the progress made in preparation for the mobilization of the new American Army at Camp Dix during the period from July 17, when the picture at the top of the page was taken, to Oct. 13, when the one next below was taken. The artillery section may be seen in the distance in the upper left-hand corner of this picture. The picture at the bottom of the opposite page gives a better view of some of the officers' quarters and a part of one of the drill grounds.

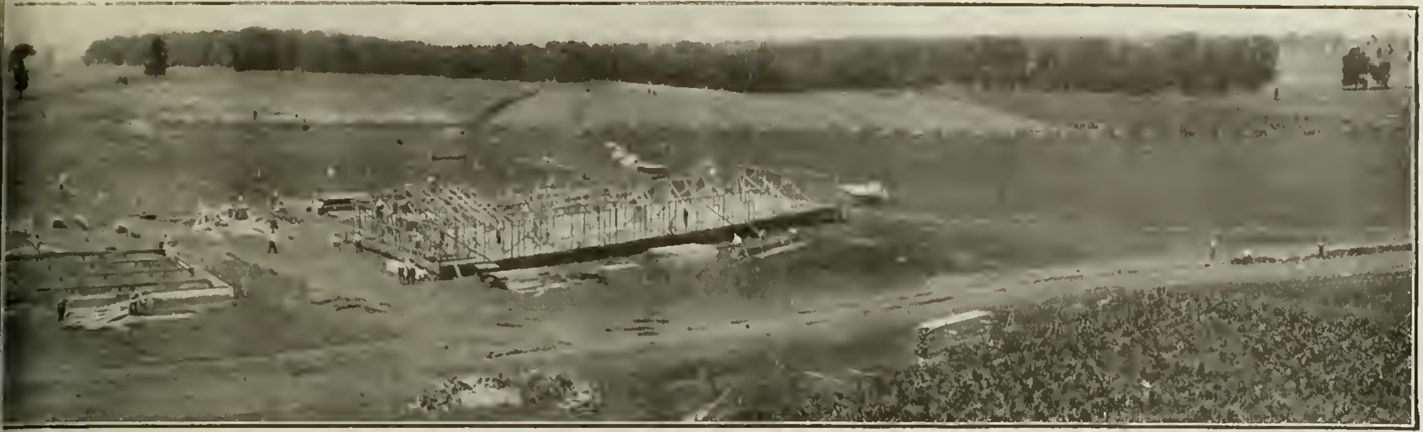
The building construction almost throughout is of the double-siding and double-floor type, with felt or tar paper between and tar-felt roofing, making at once inexpensive, easily built and warm buildings. Hand labor in all operations was reduced to a minimum. Semi-portable sawtables, driven by small gasoline engines mounted beneath, were much in evidence.

Road building constitutes an important element in all military operations and is one of the first engineering enterprises of any camp. Clamshell buckets were used for unloading road-making and like material from the railway cars wherever possible, and self-dumping motor trucks were used for distribution within the grounds.

The barracks generally are two-story frame buildings 43 ft. wide by 140 ft. long, with a one-story "cook shop" at one end, and each is designed as sleeping quarters and mess for about 175 men. They are heated by two large heaters on each floor. The officers' quarters are small one-story buildings, 20 ft. wide with an average length of 112 ft. divided into living quarters, offices and kitchen, so that heating by stoves is not practicable.

A small cast-iron sectional steam boiler is located in a pit at the rear of the building, and a loop of piping runs under the floor with short risers through the floor to the radiators—an arrangement at once as simple and "foolproof" as seems possible to design. The camp is provided with a complete system of roads, sewerage, water supply and fire protection, telephone communication and electric service. Standardization in design is thoroughly carried out.

The base hospital group of buildings is located at a considerable distance from the barracks. This is the only group supplied by a central heating plant. The boiler plant consists of a battery of eight boilers rated at 150 hp. each, seven of which are to operate at low pressure for heating direct and one at high pressure for the kitchen and other uses where a continuous high-pressure steam service is needed. Hot water is supplied through a 2½-in. flow and return line from a large storage tank containing a steam coil. The low-pressure boilers are fed by the "service main" pressure and the high-pressure by means of a feed pump. The boilers are hand-fired and each has an independent stack 33 in. diameter. The piping system is divided into two sections, but cross connections are provided at several points for use in case of emergency, expansion bends and loops are used on the 10- and 8-in. lines and slip expansion joints on all smaller sizes. The wards are piped independently with the "drainage slope" toward the extreme end where the condensate is discharged through a trap. The total radiation in the hospital group is upward of 90,000 sq.ft. The main distributing



Near Wrightstown, New Jersey

lines are of approximately the following size and lengths: 1150 ft. of 10-in., 1300 ft. 8-in., 1600 ft. 6-in., 1800 ft. 4-in. and 2200 ft. of 3-in. pipe.

The camp is supplied with ice from an electrically driven ice plant in a section of the grounds convenient to the railway, where meats and other perishable commissary supplies are received and distributed. By courtesy of Capt. H. A. Gilbert access to all proper data was given to a representative of *Power*. The photographs were supplied by W. N. Jennings, 1305 Arch St., Philadelphia, Penn., the official photographer for the contractors, Irwin & Leighton.

OFFICERS' QUARTERS AND PART OF ONE OF THE DRILL GROUNDS

Methods of Drying Out Flooded Power Plant Equipment

By NORMAN L. REA
Construction Engineer, General Electric Co.

Various schemes that may be employed for drying out electrical equipment after a power plant has been flooded are discussed. The advantages and disadvantages of the various methods are pointed out.

FLOODS are no respecters of power houses, and the majority of troublemen have to clean up the mess left by one of them sooner or later. Of course the old adage, "Many men of many minds," applies in this work as in everything else, and countless schemes have been tried with all degrees of success. In fact, some of the schemes have made matters worse instead of better. Possibly a brief outline of a few good ways and a caution regarding some of the bad ones may be of assistance to some brother in distress.

A power house after a flood is a sorry sight—oil and river silt smeared over everything and unlimited driftwood and sand everywhere. The first thing of course, is a thorough cleaning, and this should be started immediately and carried on while stock is being taken of the local facilities and a plan of campaign laid out. The machines should be thoroughly washed with water under pressure (a fire hose works very nicely), and all bright parts dried and oiled to prevent rusting. The bearings should also have immediate attention to prevent rusting. They should be thoroughly cleaned of all dirt and grit, dried and oiled before rust gets a foothold.

Run Machine To Assist in the Drying

Just as soon as the machines can be turned over, they should be brought up to speed and run without field as the windage will assist materially in the drying. The building should also be cleaned and heated to drive out the dampness. This heating will also assist considerably in drying the machines. Special care should be taken to ventilate the power station so that the damp warm air may be replaced by dry air.

In an alternating-current station the exciters should, of course, have the first attention, although the alternators should be run on windage while the exciters are drying. Small exciters have been dried out by windage and a plumber's furnace under the commutator. Care should be taken not to get the commutator too hot.

The machines may also be baked in a temporary oven or hot air blown through them. One must remember, however, that heat alone will not do the trick. The moisture must be removed, and nothing else will carry away moisture like hot, dry air.

In many cases machines have been surrounded with steam radiators and carefully covered with several thicknesses of tarpaulins. After several days of this "drying," those in charge of the job were greatly surprised to find the insulation resistance considerably lower than when the work was started. Steaming is all right for clams, but is poor treatment for water-soaked insulation. A little planning and a few bafflers will usually cause the hot air from the radiators to flow through the machine by its natural draft. Hot air may be forced through the machine by a blower when power is available. The foregoing methods are good when it is impossible to run the machines owing to lack of mechanical power, or in the case of synchronous motors. It is especially applicable to exciters. Of course the machine should be run if at all possible, and the heating arranged so that the natural windage will assist the hot-air circulation. The heat may be supplied by steam radiators, hot-air furnaces, stoves, electric heaters or lamp banks.

No two jobs are alike, and there is an excellent chance for a man to show his ingenuity and skill in the best use of local resources. An open flame should not be used. In one case where coke fires were used with a blower, the coke dust, ashes and fumes were blown into the windings. After several days' treatment, the windings showed a lower insulation resistance than when the drying was started. This was apparently due to the dust lodging in the windings, and the fumes may have caused copper corrosion.

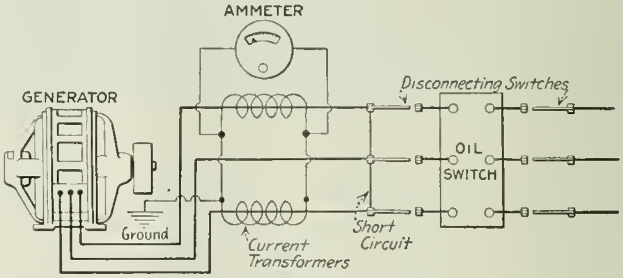


FIG. 1. CONNECTIONS FOR SHORT-CIRCUIT HEAT RUN ON ALTERNATING-CURRENT GENERATORS

The temperature of the hot air with any arrangement should not be higher than 100 deg. C., and 80 deg. C. is a safer temperature, because some insulating compounds change at fairly low temperatures. The fire risk must always be kept in mind and excessive temperatures avoided.

As soon as an exciter is dry enough or direct current is available from any source, all the alternating-current generators should be put on a short-circuit heat run. This is done by short-circuiting all phases through the proper size current transformers and ammeter, as shown in Fig. 1, and applying a weak field, which is increased slowly until the armature winding is carrying full-load current. Generators with an overload rating may be run with this overload current. However, many machines are now given a maximum rating, and any current in excess of this rating may damage the windings. The short-circuit of the generators should be made between the generator and the oil switch as in the figure, or the oil switch blocked in the closed position and the load handled by the field current exclusively, because opening the armature circuit during the short-circuit run is quite likely to puncture the wet insulation.

The short-circuit heat run should be continued until the insulation resistance reaches a proper value. This resistance will, of course, vary with the size of the machine, kind of insulation, voltage, etc. In general the insulation resistance indicates little more than the condition of the insulation as regards moisture. The rate of change of the resistance as the heat run progresses is, perhaps, the best indication as to when the drying has been carried far enough. The drier the insulation becomes the slower the insulation resistance will increase. Judgment must be used in deciding when it is safe to stop the short-circuit run.

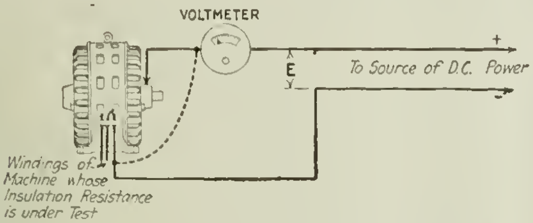

FIG. 2. INSULATION-TEST CONNECTIONS

In many cases a Wheatstone bridge or megger is not available for measuring the insulation resistance. The following method will give results accurate enough for general use: Connect one side of a direct-current circuit to the windings to be tested, connect the other side of this circuit to a portable voltmeter, and then read the voltage when the free side of the voltmeter is connected to the circuit where it is attached to the windings, as indicated by the dotted line, Fig. 2. Call this reading E. Then connect the free side of the voltmeter to to the frame of the machine, as shown in full lines in the figure, being careful to get a good contact, and call this reading E_1. Then the insulation resistance $R = \frac{R_1(E - E_1)}{E_1}$, where R equals the insulation resistance and R_1 the resistance of the voltmeter; the latter value is usually given inside the meter cover.

Before using any commercial circuit for insulation testing, voltmeter tests must be made to determine if the circuit is grounded. One side of the circuit must be free from grounds, and the ungrounded side used in series with the voltmeter when testing. Failure to test for grounds has led to short-circuits and personal injuries.

After the short-circuit test is ended, the machines should be brought up to normal voltage slowly and should be inspected very carefully while the voltage is building up. Incipient breakdowns can usually be seen, heard or smelled and the field circuit opened before the windings or punchings are materially damaged. One man should stand by the field switch to open it instantly on signal from the men watching the machines.

The machine should be run several hours at normal voltage or 10 per cent. above normal to heat the iron thoroughly before going into regular service. It is advisable to continue the drying of very large generators 24 hours longer as follows: Two hours at full-load current on short-circuit, then two hours 10 per cent. above normal voltage open-circuit. These alternating runs heat both the iron and the windings thoroughly and drive out any remaining moisture.

There is always a tendency to hurry the machines into service, and great pressure is usually brought to bear on the man in charge of the drying. It is imperative to "make haste slowly," as a day or two longer drying is a lot better than a burned-out machine with the consequent delay and expense.

Large direct-current machines that have been submerged usually give the most trouble in the commutator, especially if the machines are flooded when hot. Apparently the sudden cooling causes a partial vacuum under the commutator bars and some water is drawn into this space. The heating of the commutator causes expansion which traps this water. Consequently, the machine responds very slowly to direct heat on the commutator or short-circuit heat runs, unless some exit is provided for the moisture. The following scheme has produced excellent results on several occasions.

Every other bolt is removed from the outside clamping flange of the commutator. Then some small bent funnels were made, shaped like a ship's ventilator hood, as shown in Fig. 3 at *A*. One of these air scoops was fastened in every other hole and faced in the direction of rotation as in the figure. The ventilating funnels were made up by a local tinsmith and twisted into the holes, after which no trouble was experienced by their coming out. Of course all of them were used on fairly slow-speed machines, and as the funnels were down near the shaft, they did not move very fast. The machine must be run at reduced speed, to prevent injury to the commutator. The scoops force air through the space under the commutator bars and out the other holes, materially hastening the drying. In some cases one can actually see the vapor coming from the open holes.

There are several ways of heating direct-current machines. The various methods of drying with hot air, previously outlined, can, of course, be applied when the machine cannot be run or there is no outside power available. The simplest, when the machine can be run and direct current is available, is a short-circuited heat run. The series field should be reversed to buck the shunt coils and the armature short-circuited through an ammeter and a circuit-breaker or fuse.

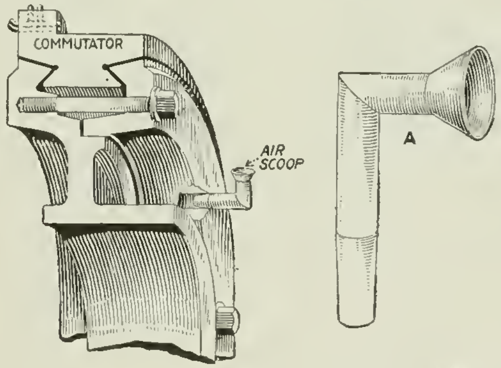

FIG. 3. AIR SCOOPS FOR VENTILATING COMMUTATOR

Then a very small current is sent through the shunt field and gradually increased until full-load current flows through the short-circuit. Extreme care must be used in first throwing on the short-circuit, for unless the series-field windings are bucking the shunt, the machine will pick up as a series generator on short-circuit, with surprising and sometimes disastrous results. Unless the circuit-breaker can be set very low, it is advisable to connect a small fuse in the circuit for the first trial.

In some cases the brushes may need shifting forward from the regular running positions so that the resulting sparking will increase the heating of the commutator.

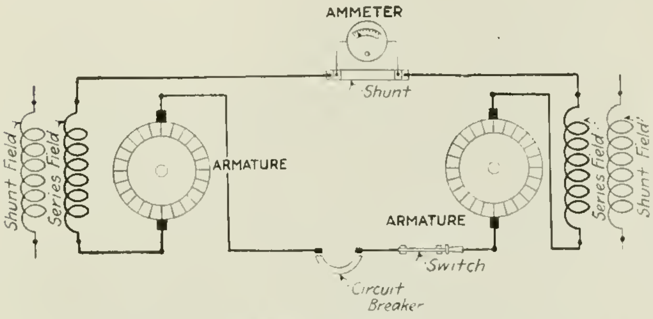

FIG. 4. CONNECTIONS FOR HEAT RUN ON TWO COMPOUND-WOUND DIRECT-CURRENT GENERATORS

This should not be carried far enough to spoil the commutator's surface and make turning or grinding necessary.

Where no exciting current was available on a job involving two large engine-driven machines—after considerable study the following scheme was used with excellent results: The series field of one machine was bucked so that it opposed the tendency to pick up as a series generator, then the two machines were connected in series through an ammeter shunt and circuit-breaker. Both machines were equipped with air scoops on the commutator end flange. The machine with the bucked field was brought up to half-speed. Then the other machine was turned over slowly and the speed gradually increased until full-load current was flowing through the combination. This required about 20 per cent. of normal speed for the generator. Fig. 4 shows the scheme of connections used. Both shunt-field windings were left open, as there was no way of exciting them.

Sometimes the commutator heating can be materially assisted by one or two plumber's furnaces turned low and placed with their tops a foot or two below the commutator. Care should be taken not to heat the commutator too quickly or too hot. Most commutators are pressed on an extension of the armature spider hub, and the pressing fit allowance is usually small. Too rapid heating may, therefore, expand the commutator enough to loosen it on the shaft. In fact, this was first discovered by a commutator starting to walk off its seat. Fortunately, this was noticed before any damage resulted, and the heat run was discontinued while it was jacked back to its proper place. The windings should not be heated over 100 deg. C., although the commutator will safely stand temperatures above 100 deg. C. "It is better, however, to be safe than sorry," therefore, use 80 deg. C. as a maximum on the windings and 100 deg. on the commutator. These values are actual temperatures and not a rise above the room temperature.

The drying should be continued until the insulation resistance reaches a safe value and the machine then brought up to normal voltage very slowly. The remarks under alternating-current generator drying apply equally well to direct-current machines, except that it is unnecessary to alternate the open and short-circuit runs.

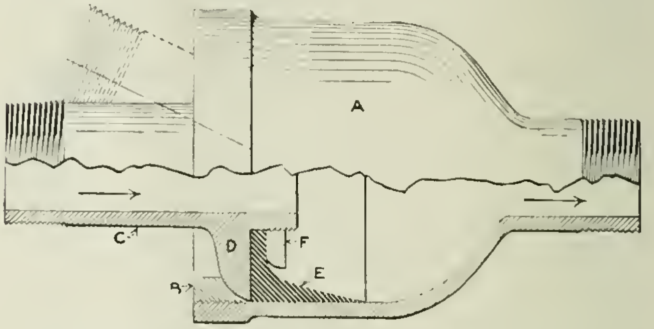
The insulation resistance is usually considerably lower than the alternators, but the drying takes about the same length of time, especially if water gets into the commutator.

Berry Flexible Joint

Various arrangements are used in pipe-line construction to provide for expansion and contraction and to release the pipes from strain, jarring and vibration. Expansion bends, swing joints, unions and sundry types of flexible joints are used for this purpose. Included in the line of flexible connections is the new Berry flexible joint, manufactured by the Iron Clad Joint Co., 400 Godchaux Building, New Orleans, La. It is arranged for use with steam, air or water, and is illustrated herewith.

This is not a metal-ball joint, but it has the action of one, and it is designed to take care of vibration, expansion and contraction. It is so flexible that it can be swung automatically in any direction and always leave a full and unobstructed area to the flow of liquid or gas.

The device consists of six parts, as shown. The shell, or bell end, *A* is threaded on the inside for a bearing ring. The pipe *C*, forming the other pipe connection, is made with a flange *D* with a machined curved surface on the side that has a bearing with the ring *B*. The flange is made flat on the opposite side, so that the cup-shaped flexible member *E* has a flat surface against which it is firmly pressed by the ring *F* when screwed up on the thread on the inner end of the connection *C*.



SEMI-SECTIONAL VIEW OF THE FLEXIBLE JOINT

With the pressure entering the joint in the direction of the arrows, the flexible member *E* is forced out against the inside surface of the body *A*, making a steam-tight joint regardless of the angle in which the connection *C* may be.

The Salt Lake *Tribune* recently published the following:

> Consent was voted yesterday morning by the City Commission for the Utah Power and Light Co. to drain condensed water from its heating system into the sewer. It was explained to the commission that distilled water that returns from the steam pipes is injurious to the boilers if returned to them because of its activity as a solvent.

Nothing like reading the newspapers for getting valuable engineering information—some engineers don't know about this.—*W. E. Jacob.*

Relief for New England Coal Situation

By CHARLES H. BROMLEY

Governor McCall of Massachusetts, together with Fuel Administrator Storrow and other governors and senators from New England, visit Washington to force relief for coal situation. Railroads and trolley-car service reduced to avoid immediate depletion of supply. Navy responsible for serious withdrawal of large-towing capacity. New England short nearly 8,000,000 tons of bituminous coal on January First.

NEW England's coal situation was never more acute. And there is the devil to pay about it, as Washington learned last week. Fuel Administrator Storrow and Governor McCall of Massachusetts, accompanied by other governors and senators from New England, visited the capital to force immediate action to relieve the grave fuel condition of the six Northeastern States. The outlook therefore is brighter, though it should be understood by fuel users that a shortage of the most severe kind cannot now be avoided; nevertheless it will be of shorter duration than it would have been but for the impressive visit of the New England delegation to Mr. Garfield at Washington. Governor McCall was not sparing in his condemnation of those responsible for New England's plight. The Navy Department particularly was censured by the Governor for its too wholesale commandeering of ocean tugs, leaving a shortage of power craft to tow loaded coal barges from Hampton Roads to New England ports. This is what the Governor had to say: "The Secretary of the Navy is said to have proudly declared before a committee of Congress the other day that we have a thousand ships in the Navy; but if those ships, according to tonnage, could begin to inflict the damage on the Germans that the withdrawal of coal tugs, according to their tonnage, has inflicted on the northeastern part of our own country, it is doubtful if the Germans would last a week."

One effect of the Governor's visit will, it is promised, be the stopping of cross-hauling; that is, no coal trains shall pass each other running in opposite directions. The Chesapeake & Ohio R.R. is to haul coal from the mines to Hampton Roads for New England delivery.

It is charged that while coal shortage is due to rail-transportation difficulties chiefly, the roads would have three-thousand locomotives for coal hauling if the locomotive shops had not been commandeered for the building of locomotives for Russia and France.

Capt. Arthur Crowley, who is the marine representative of the New England Fuel Administration, is confident of improvement in towing capacity for barges to New England ports. The Navy took one-fourth of the towing capacity of the Reading road used in the New England trade, and the ten tugs taken from the towing service between Hampton Roads and New England have left a shortage of such capacity amounting to many hundreds of thousands of tons per year. Much of this will likely be restored as the result of the efforts of Fuel Administrator Storrow.

There is serious congestion at Hampton Roads. The Boston Elevated Railroad Co.'s chartered steamer "Everett" has been, at this writing, riding at anchor for eight days awaiting opportunity to load, which she can do in eight hours. Her capacity is 7200 tons. To facilitate coal leaving Hampton Roads, ships may now pass in and out of the harbor at any time, day or night. The Boston & Maine R.R., according to President Hustis, requires 5000 tons of coal per day for its locomotives; but for the last thirty days only 2000 tons per day was received. The Boston Elevated system and the Bay State railways also must greatly decrease service to make the coal supply go far enough to meet the urgent transportation demands. Service on many of the suburban lines will be stopped except for a few hours morning and evening. The illustration shows the coal storage plant of the Boston Elevated Railway Co.'s South Boston station.

Though Thursday and Sunday nights are the "lightless" ones in Boston, there is a very noticeable absence of non-essential illumination every night of the week. Boston certainly responds much better to the pleas of the Fuel Administrator than does New York and Chicago, particularly.

The following data, chiefly from the office of the New England Fuel Administrator, show the coal situation as it is:

RECEIPTS OF BITUMINOUS COAL FIRST TEN MONTHS, 1917

	Net Tons
All rail (for commercial and railroad use)	9,267,925
Tidewater (for commercial and railroad use)	11,376,519
Total	20,644,444
Requirements for 1917	32,574.902
If receipts for remainder of the year continued at same rate as given above for first ten months, the total receipts for New England for year 1918 will be	24,773,332
On Jan. 1, 1918, the New England shortage of bituminous will thus be.	7,801,570

NEW ENGLAND RECEIPTS OF BITUMINOUS COAL, NET TONS, FOR THE FIRST TEN MONTHS, 1917

Company Coal:		
First 10 months actual, three big roads	3,168,124	
First 10 months actual, Central Vermont	5,629	
First 10 months actual, Rutland	60,447	
Total company	3,234,200	3,234,200
Commercial coal:		
First 10 months actual, three big roads	6,011,748	
First 10 months actual, Central Vermont	54,715	
First 10 months actual, Rutland	203,262	
Total commercial	6,269,725	6,269,725
Total company and commercial		9,503,925
Less exports to Canada (Sept. and Oct. est.)		236,000
Net total		9,267,925
Tidewater receipts 10 months		11,376,519
Grand total, 10 months		20,644,444
Requirements for 1917 as previously estimated		32,574,902
If receipts for last two months should equal 1/5 of first 10 months they would equal	4,128,888	
Plus 10 months' receipts	20,644.444	
Total	24,773,332	24,773,332
Shortage Jan. 1, 1918, would thus be.		7,801,570

NEW ENGLAND BITUMINOUS COAL CONSUMPTION IN 1916, NET TONS*

Tidewater coal	15,665,499
All-rail coal	10,230,253
	25,895,752
Depletion of reserves	1,250,000
	27,145,752

* These tidewater figures were obtained from statistics gathered with great care at each New England port by the Boston Chamber of Commerce. The all-rail figures were reported directly to the New England Coal Committee by the New England railroads. The coal used by the New England railroads was 5,916,789, and is included in all-rail and tidewater figures.

REQUIREMENTS FOR 1917

Consumption, 1916	27,145,752	
Add 20 per cent	5,429,150	
		32,574,902

Twenty per cent. increase for 1917 over 1916 is probably low for soft coal, as the New England industries are working this year under the most intensive pressure ever known and probably to a greater extent than any other section of the country, except perhaps the steel-making districts.

New England normally carries two-thirds of its soft coal by water and one-third by rail. Owing to war conditions many of the New England coal-carrying bottoms have gone off the coast and these cannot be replaced. The already overloaded railroads of New England cannot assume added burdens. Indeed, owing to lack of motive power the capacity of these railroads will soon be cut down at least 25 per cent. by winter storms and cold weather. The capacity of the coal-carrying fleet will likewise be cut down at least 25 per cent. by winter weather. New England's coal problem is quite as much one of transportation as of securing the coal. If New England goes into January 7,500,000 tons of coal short, as the figures given indicate, this not only cannot possibly be made up, but will inevitably rapidly grow worse owing to lack of transportation facilities.

The following is from the report of the Federal Trade Commission, June 20, 1917, Senate Document No. 50: "The situation in New England is made acute because of the disruption and disorganization of barge transportation. The cost of the water haul from New York to Boston has been increased from 50c. a ton to as high as $3 a ton. From Newport News bituminous coal is paying $3.50 to $4 per net ton instead of the normal of 70 to 90c. to New England."

NEW ENGLAND A SPOT SOFT-COAL MARKET

By long custom of the trade, New England has been preëminently a spot-coal market. The mines have been glad to sell their coal for cash to New England consumers during the summer months while other localities were less ready to buy. New England manufacturers and householders have learned the necessity of accumulating a supply of coal during the summer months owing to the inability of the rail- and water-transportation facilities to carry coal as fast as it must be burned during the winter months. Owing to its greater distance from the mines, New England is considered a less desirable market, and at times consumers have been obliged, in order to divert coal in their direction, to bid higher prices than other localities.

The situation in New England in regard to spot coal became acute as soon as the $3 tentative maximum price was put into effect by the Coal Production Committee, because consumers were prevented from bidding higher than other localities for the coal they needed, and the mines and originating railroads at the same price preferred to improve their inadequate car supply by selling coal nearer the mines and so getting their cars back sooner.

Now that the $2 price has gone into effect, the situation has grown, if possible, worse. A very large number of the New England manufacturers who are depending upon buying spot coal for their own use have been completely shut off. Most of the coal is going to fill contracts at higher prices, and if there is any balance of free coal it is being sold nearer the mines and New England today cannot buy a car of spot coal. This is the situation that needs immediate attention.

SHORTAGE OF ANTHRACITE COAL

On the first of May shipments of anthracite were 300,000 tons short of a year ago. By the first of July shipments had increased so that the total for the six months was nearly equal to a year ago. This had not wholly relieved the situation because no coal was provided for the normal growth of 5 or 6 per cent., and moreover, the percentage of domestic or household sizes had dropped substantially so that household coal was shorter than the gross figures would indicate; but during July and August shipments of anthracite continued to show gains over last year.

It does not appear that the anthracite situation in New England needs immediate attention, or at least that it is as grave as the soft-coal situation. Anthracite shipments to New England for the first ten months of 1917 were 10,227,010 tons; for the first ten months of 1916, 9,220,760 tons.

The industrial centers of New England are being assisted in fuel conservation as related to boiler rooms, by inspectors from the offices of the fuel administrations and by the coöperation of the local associations and sections of the engineering societies. These representatives are versed in firing methods and go into the boiler rooms to assist, if possible, in teaching firemen how to get the most out of the coal.

The President has now taken over the railroads and the steamship lines operated by the roads. The Fuel Administrator seriously contemplates "complete control of coal if the war lasts for a long while." The pity is that men in such high office do not see that it will. Likely Dr. Garfield will assume complete control, and along lines suggested in *Power* for Dec. 18, 1917, page 832, sooner than he at this writing seems to contemplate. With the roads now fully under Government control and with the more complete supervision of the coal industry by the Fuel Administrator, New England should get relief as soon as it is physically possible to do so; that is, there do not now exist any real reasons for Government failure—except the uncertain link, labor, which everyone hopes, will hold.

NEW ENGLAND HURT BY LONG HAULS

It seems certain that before relief can come to many producers of steam and power now crying for coal, the Fuel Administration must abrogate all contracts now existing between dealers, consumers and coal-mine operators. The present panicky situation is conducive to hoarding, and operators will not, of course, put out any free coal while there is opportunity for it to bring higher than Government prescribed prices. The New England Fuel Administrator truly tells how price fixing by the Government has operated to the serious disadvantage of the Northeastern States. New England, by reason of its geographical position, necessitates comparatively longer hauls at a time of extreme car shortage, which has made coal operators reluctant to accept New England's trade. But these are propitious times, and therefore this disadvantageous period is likely to be of short duration. Its very severity compels immediate alleviation to the limit of physical possibilities.

With industries vital to the war subject to interruptions on account of lack of fuel, with the railroads compelled to withdraw train after train from service for the same cause, with scores of ships, ships so very vital to the success of our arms and those of our Allies, detained for days at their ports because of empty bunkers, to say nothing of domestic suffering, who now dares to belittle the fuel shortage as did the exploiters such a short time ago who at the time knew full well the gravity of the impending crisis?

The severe effect of car shortage on loss of coal output at the mines is shown by the Geological Survey report for Dec. 29, from which the following table, condensed, is taken:

	Week Ended	Percentage of Full-Time Output Lost On Account of Car Shortage
Illinois	Dec. 8	9.1
	Dec. 15	17.0
Indiana	Dec. 8	5.4
	Dec. 15	18.4
Ohio	Dec. 8	31.7
	Dec. 15	57.1
Pennsylvania:		
Western Pennsylvania	Dec. 8	12.6
	Dec. 15	33.6
Irwin Gas	Dec. 8	14.3
	Dec. 15	28.3
Central Pennsylvania	Dec. 8	14.1
	Dec. 15	28.3
Somerset Co	Dec. 8	36.2
	Dec. 15	52.5
West Virginia:		
Winding Gulf	Dec. 8	25.8
	Dec. 15	41.9
Panhandle	Dec. 8	20.0
	Dec. 15	24.2
Pocahontas and New River	Dec. 8	34.0
	Dec. 15	46.4
High Volatile of S. W. Va	Dec. 8	56.9
	Dec. 15	59.9
Junior—Philippi	Dec. 8	35.6
	Dec. 15	35.7
Fairmont	Dec. 8	31.6
	Dec. 15	40.8
Cumberland—Piedmont	Dec. 8	13.7
	Dec. 15	34.9
Kentucky:		
Hazard Field	Dec. 8	35.4
	Dec. 15	65.5
Northeastern Kentucky	Dec. 8	38.4
	Dec. 15	60.9
Western Kentucky	Dec. 8	31.4
	Dec. 15	40.2
Southern Appalachian	Dec. 8	12.0
	Dec. 15	18.8
Southwestern Virginia	Dec. 8	3.0
	Dec. 15	8.2

Notice that Ohio lost 57 per cent. of its full-time output due to car shortage; Somerset County, Penn., 52.5 per cent.; Western Pennsylvania, 33 per cent.; the important fields of West Virginia 42, 24, 46, 60, 35 and 40 per cent., respectively, while the Cumberland and Kentucky fields suffered similarly.

TAKING OUT THE CLINKERS

Determining Boiler Efficiency by Co₂ Analyses and Flue Temperatures

By HAYLETT O'NEILL

The author gives several charts with the aid of which the boiler efficiency may be closely approximated when the CO_2 and flue temperatures are known. The purpose of the article is to enable the engineer to obtain valuable operating data for practical use by means of simple and cheap instruments.

TO INVESTIGATE the cost of its product, a certain power company spends thousands of dollars a year experimenting in boiler-furnace operation. Some tests cost over a hundred dollars each. The resulting profits are manyfold to a large company because the expense of experimenting is shared by a hundred large units, and the gross returns are multiplied accordingly. But the average industrial plant cannot afford special coal and water scales, special measuring instruments and piping and the technical help for complete plant tests. The large power producers must do most of the pioneer work in boiler-plant design and operation. Easy experimental methods would undoubtedly lead to radical developments in industrial power-plant methods.

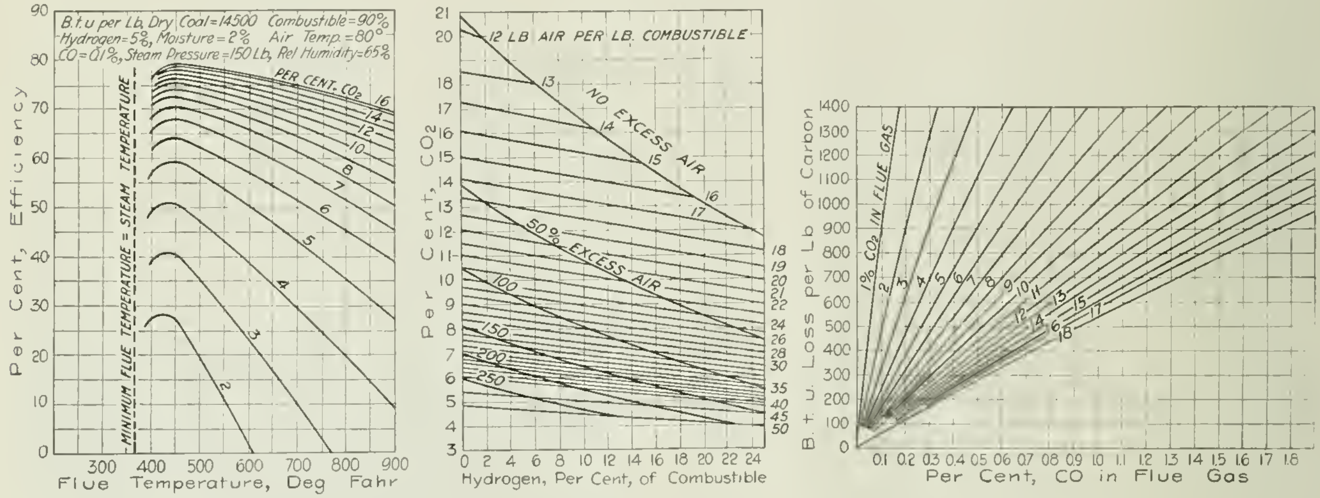

FIG. 1 FIG. 2 FIG. 3

FIGS. 1 TO 3. CHARTS SHOWING VARIOUS LOSSES IN STEAM-BOILER FURNACES

Fig. 1—Combined boiler efficiency indicated by CO_2 and flue temperature. Fig. 2—Effect of excess air on CO_2 in gas varying amounts of hydrogen in fuel. Fig. 3—Furnace loss on account of incomplete combustion of carbon

The object of this writing is to point out the significance of a simple and cheap method for determining evaporative boiler efficiency. This method is to measure the average temperature of the flue gas where the gas leaves the boiler-heating surface, to analyze for CO_2 content an average sample of flue gas from the same source, and to apply these two determinations to the efficiency chart, Fig. 1. Thus, flue-gas temperature and CO_2 percentage are assumed to be the only variable factors of boiler efficiency. This is computed by dividing the difference between the heating value of the coal and the calculated losses by the heating value of the coal.

In calculating the total losses, certain operating conditions and accompanying losses actually variable, are assumed constant and there is necessarily an error in the computed efficiency. However, where Eastern coals are burned, such error is usually less than 2.5 per cent., sufficiently precise for comparative results. It is well to note conditions under which such assumed losses may vary. For example, the refuse loss here is assumed constant, while it actually varies according to the coal and the design and the operation of the grates. The radiation loss is assumed equal to 4 per cent. of the boiler output at builder's rating. In very large units, the loss is probably nearer 2 per cent. A boiler in a cold climate, other things being equal, cannot be so commercially efficient as one surrounded by air averaging 90 deg. But the error from the foregoing assumption will, upon close analyses of the charts, be negligible compared to the losses accurately measured by the flue-gas temperature and the percentage of CO_2.

Heat losses may be divided into two classes: Those measured by CO_2 and flue temperature, and those measured by flue temperature only.

Loss in Dry Flue Gas—By itself, the percentage of CO_2 does not even measure boiler efficiency. In simple language it indicates the weight ratio of air to fuel when the proximate analysis of the coal is known. A CO_2 content in flue gas, formed from pure carbon burned in air, indicates one proportion of air to fuel, the same percentage CO_2 from the combustion of natural gas or soft coal indicates another. This difference is due largely to the varied proportions of hydrogen in the fuel hydrocarbons or the volatile combustible matter. Thus 8 per cent. CO_2 from a natural-gas burner may mean just as good an air ratio as 12 per cent from a soft-coal furnace. Hydrogen burns to water vapor, condenses in the gas-analyzing apparatus and thus the percentage of nitrogen and gases insoluble in the Orsat chemicals is increased. The greater the percentage of hydrogen the less will be the possible CO_2 percentage. Fig. 2 indicates a possibility of 20.9 per cent. CO_2 from the burning of pure carbon and an impossibility of greater than 18.5 to 19 per cent. CO_2 for soft coal containing 4 or 5 per cent. hydrogen.

In hand firing, where heaps of green coal are generally quickly thrown upon the grates, volatile matter therein is distilled and burned first in greater proportions than the fixed carbon. Low CO_2 at first results, incorrectly indicating an excessive air supply. After most of the volatile matter is distilled, the higher CO_2 follows, indicating a lower than actual air ratio. A stoker feeding coal at a uniform rate produces CO_2 more nearly indicative of the actual air mixture.

In any event, snap analyses of flue gas are worthless as clues to the problem of producing the lower fuel cost per unit of manufactured product. A recording analyzer helps in the study of transient furnace conditions, but records of individual analyses are open, in some degree, to the foregoing objection. Then too, the boiler must be large to acquire a profit from an instrument costing $250 to $300.

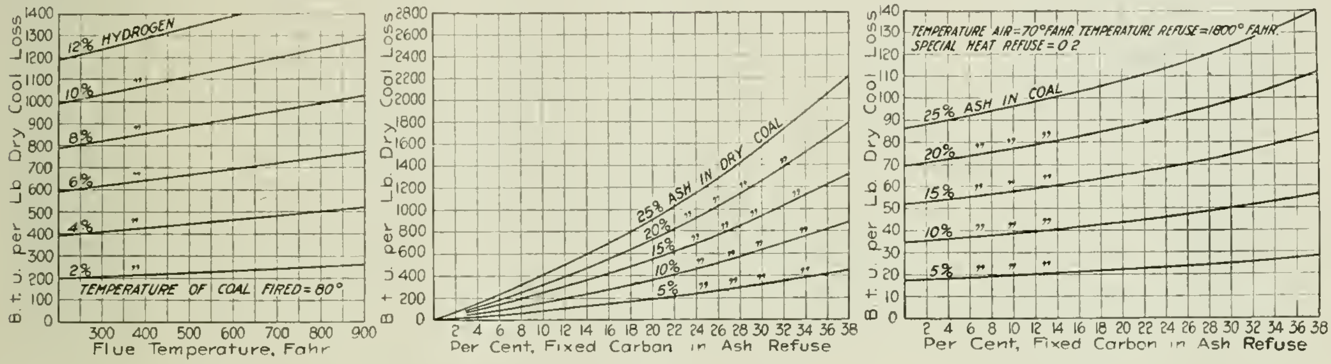

FIG. 4 FIG. 5 FIG. 6

FIGS. 4 TO 6. CHARTS SHOWING VARIOUS LOSSES IN STEAM-BOILER FURNACES

Fig. 4—Loss on account of hydrogen in coal. Fig. 5—Heat loss to ashpit from unburned carbon. Fig. 6—Sensible heat loss to ashpit

A plain Orsat CO_2 analysis of an average tank sample of gas collected over a given period shows all the flue gas analytical data of interest to the average plant superintendent. A sampling tank costs about one-tenth the price of a recorder.

The heat loss in dry gas at flue temperature is calculated as follows:

$$\textit{Heat Loss (B.t.u. per lb. of dry coal)} = WS(Tf - Ta)$$

where

W = Pounds of flue gas per pound of coal determined from proximate analysis of coal and Fig. 1;

S = Specific heat of flue gas, assumed constant for all temperatures;

Ta = Temperature of the air assumed at 80 deg. F.;

Tf = Temperature of flue gas.

Loss Indicated by Presence of CO in Flue Gas—Carbon monoxide (CO) is a result of the incomplete combustion of carbon and oxygen, and while the loss from it is not strictly measured by the percentage of CO_2, it is affected thereby. For example, from Fig. 3, 0.1 per cent. CO shows a loss of 320 heat units per pound of carbon when the flue gas is 3 per cent. CO_2, but a loss of only 70 units when the CO_2 is 14 per cent.; that is, the less the excess air the less the proportionate loss from incomplete combustion of coal. CO indicates a shortage of air required for complete combustion either locally or generally, and usually results from too heavy a fire for a given draft, stratification of gas on account of an uneven fire, or from the passage of hot CO_2 over soot-laden tubes where it combines with enough carbon to form CO. Thus, CO_2 plus CO = 2CO. Most furnaces get too much air rather than too little, and generally CO is absent. In the calculated efficiency chart, CO is assumed at 0.1 per cent.

Loss on Account of Moisture in the Air Supplied for Combustion—All air contains moisture indicated in definite proportions by the wet- and dry-bulb temperatures as illustrated in Fig. 4. These temperatures, together with the percentage of CO_2, measure the ratio of moisture in air per pound of fuel. The loss from superheating this moisture to flue temperature is usually inconsiderable. In the efficiency chart it is calculated at about 12 B.t.u. per pound of coal burned.

Loss on Account of Refuse—Soft-coal refuse usually contains both volatile and fixed carbon; but generally the volatile is negligible. Fig. 5 shows the loss from unburned combustible calculated on the fixed-carbon basis. This loss depends not only upon the percentage of combustible in the refuse, but also upon the percentage of ash in the coal. The poorer the coal with respect to ash the higher will be the refuse loss. The quality of the coal and the design and operation of the furnace are factors in boiler efficiency. The loss due to sensible heat of the refuse shown in Fig. 6 is small.

Loss on Account of Moisture in the Fuel—Moisture fed to the furnace with the coal, evaporated and superheated to the flue temperature, carries heat up the chimney. Ordinarily, as shown in Fig. 7, this is a minute loss.

Loss on Account of Hydrogen in the Fuel—When 1 lb. of hydrogen is burned, 9 lb. of water vapor is formed. Consequently, when a pound of coal containing 5 per cent. hydrogen is burned, 0.45 lb. water vapor is formed and this as superheated steam carries about 550 heat units to the chimney. It will appear from Fig. 7 that this loss, in the case of fuel oils and natural gas high in hydrogen, may be very high.

Since the bomb calorimeter, measuring the heat value of coal, is jacketed by cold water, to absorb the latent heat in the water vapor burned hydrogen, the coal is credited with the 550 heat units which must be lost in the flue. That is, water vapor under atmospheric pressure will not condense at temperatures above 212 deg. F.; and since the flue temperature is always higher than this, the latent heat in the flue-gas vapor cannot be reclaimed to produce steam.

FIGS. 7 TO 11. CHARTS SHOWING VARIOUS LOSSES IN STEAM-BOILER FURNACES

Fig. 7—Heat loss due to moisture in coal. Fig. 8—Furnace losses measured by flue temperatures independent of CO_2. Fig. 9—Furnace losses measured by CO_2 and flue temperature. Fig 10—Furnace losses measured by flue temperature, with and independent of CO_2. Fig. 11—Relation between CO_2 and flue temperatures for constant boiler efficiency.

Loss on Account of Boiler Radiation—Depending upon the design of the setting, the radiation loss is about 4 per cent. of the rated boiler output. That is, from a 500-hp. boiler, the radiation loss is about $0.04 \times 500 \times 33{,}479 = 669{,}580$ B.t.u. per hour. The loss per unit of output will vary inversely as the output; that is, it may be infinity at zero output, and it approaches zero as the output indefinitely increases. The maximum flue-gas temperature at zero is that of boiler water. Its rise above boiler-water temperature varies almost directly with the load. Consequently, the radiation loss per unit of output and per pound of coal fired varies inversely as the rise in flue temperature above the steam temperature. This is illustrated by the hyperbolic curve of radiation loss per pound of fuel in Fig. 8.

Total Heat Losses—The general conditions assumed constant to calculate the efficiency and heat-loss curves are as follows: Combustible in coal, 90 per cent.; hydrogen in coal, 5 per cent.; moisture in coal, 2 per cent.; air temperature, 80° F.; CO, 0.1 per cent.; steam pressure, 150 lb. gage; relative humidity, 65 per cent.; combustible in refuse, 20 per cent. With these assumptions Figs. 8 and 9 respectively show heat losses measured by CO_2 percentage and flue-gas temperature and those measured only by flue-gas temperature. The combined losses are shown in Fig. 10.

Except for the radiation losses, the total heat losses are accurately determined and the error in radiation loss is practically negligible at flue temperatures above 475 deg. F. Little interest is attached to points of lower temperatures.

It appears that for any percentage of CO_2 there is a certain flue temperature at which the total heat losses per pound of fuel is a minimum, and this is the point of maximum efficiency.

To compute the efficiencies in Fig. 12, 200 B.t.u. were added to the losses to account for undetermined losses. Tables I and II illustrate the close practical accuracy of the curves.

More clearly in Fig. 11 are shown the relative values of CO_2 percentage and flue temperatures in the determination of boiler efficiency. Suppose a boiler at 70 per cent. efficiency shows 10 per cent. CO_2 and 610 deg. F. flue temperature. Let the air leakage of the boiler setting be eliminated and the firing be improved so that the CO_2 is raised to 12 per cent., but at the same time let the baffles deteriorate and allow the soot to build

TABLE II. TEST ON 650-H P. BABCOCK & WILCOX BOILER AT WATERSIDE STATION, NEW YORK CITY, BY THE NEW YORK EDISON CO., 1911

Flue Temperature, Deg. F. Observed	CO_2 per Cent. Observed	Efficiency by Regular method	Efficiency by Chart	Efficiency per Cent. Error of Chart

on the tubes until the flue temperature rises to 710 deg. F. Then the efficiency will still be about 70 per cent., and all the good operating work will be nullified by the slovenly maintenance. It is a great thing to key up the firemen, but it is just as important to key up the repair gang and have proper machinery. Notwithstanding the vast amount of literature showing the value of flue-gas analysis in boiler operation, good soot blowers and a good repair boss are the most certain elements in producing boiler-room results with given apparatus.

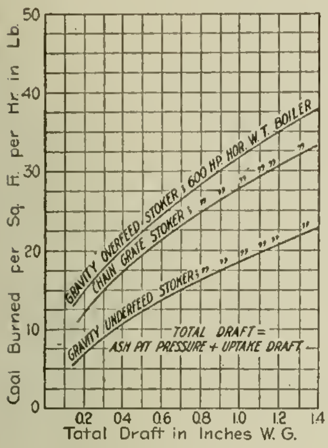

FIG. 12. EASTERN SOFT COAL COMBUSTION RATES ON DIFFERENT STOKERS

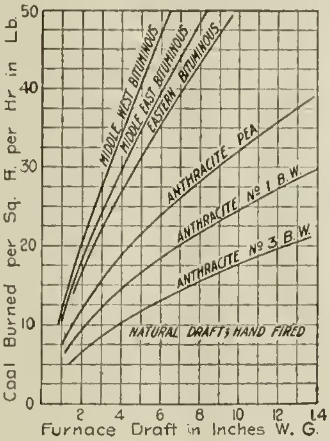

FIG. 13. COMBUSTION RATES WITH NATURAL DRAFT, HAND FIRING

A draft gage used in connection with Figs. 12 and 13 shows data necessary to determine approximately the rate of combustion, and from this and the efficiency determination the boiler output may be closely estimated.

Thus, valuable boiler-operating data can be obtained for practical use, through simple and cheap instruments, and except where extreme accuracy is essential, elaborate boiler tests are neither necessary nor advisable.

Some Pipe-Threading Hints

Did you ever hear of W. J. Willis? Probably not, because he was only an engineer in a small New England manufacturing city and the worst that could be said about him was that his wife never knew when to have his evening meal prepared, because she never knew when he would be home to eat it.

The real trouble was that Willis liked to talk shop, and he probably knew more engineers in the town than there were dead cats to the credit of his pet bulldog, which was going some. Because of his wide acquaintance it was as difficult for him to pass an engine room without stopping as it would be for a fully developed souse to pass a barroom without wanting a drink.

One evening on his way home he stepped into the engine room of a small plant, where he found young Stetson busily engaged in cutting threads on a length of pipe.

"Caught you right in the act, didn't I?" was Willis' greeting. "What are you doing? Making a lot of poor threads on that pipe end?"

"Yep," answered young Stetson, "but I guess they will answer so long as I can get the joint tight when it's made up. The threads are pretty ragged, but I'll put a lot of dope on them when they are screwed into the fitting."

"You have the same false notion that so many engineers and some pipefitters have; that is, that any kind of a thread will answer so long as it can be made tight at the first go-off. You ought to know, and you probably do know, that there is a standard thread embracing pitch, depth and length of cut, when it comes to cutting a thread, and at a steam plant almost any departure from the standard can be expected. Some of the threads are cut small and do not fit in the fittings, some are stripped and others do not have the proper taper. Often it will be found that purchased pipes have threaded ends that do not conform to the standard."

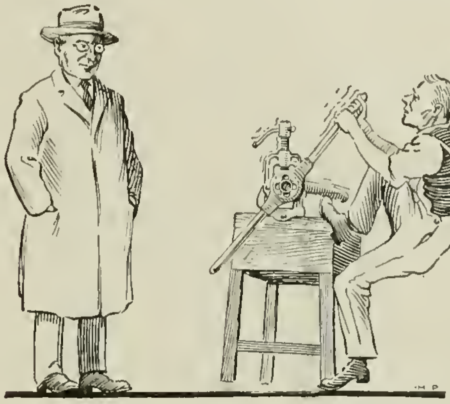

FIG. 1. "WHAT ARE YOU DOING? MAKING A LOT OF POOR THREADS?"

"Well, what's the odds so long as a fellow can make a tight joint? Let the other fellow worry after the job is up."

"Young feller," replied Willis, as he examined the stripped threads Stetson had just cut, "when making a pipe connection that is to be under steam pressure, one should remember that with the failure of such a joint there is the possibility of injuring or killing one or more workmen. There is no excuse for making a faulty joint as one can easily determine when screwing up the joint whether it is going together properly or not. Now there ain't any sense in making up a joint with the threads stripped like these are." See Fig. 2.

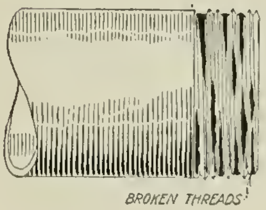

FIG. 2. STRIPPED THREADS

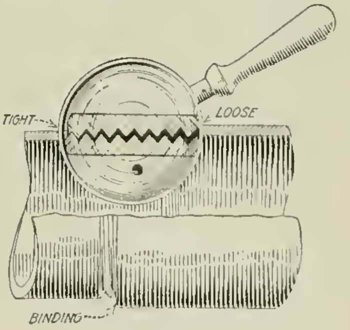

FIG. 3. A POOR PIPE JOINT

"Say, Willis, what makes these threads strip so? Of course, I don't pretend to know much about pipe work, and if you can give me a pointer it will be all to the good, and perhaps it will save a little extra work on my part; this die does go hard."

"The reason your threads are stripped in the cutting is because you did not use enough oil on the dies, or because the die is so dull it wouldn't cut musty cheese. Under such conditions when you begin to cut a thread, the chips pack in the die and the threads are stripped just as you have them here. A little care on your part will prevent that kind of work.

"Now just you take this hint, Stetson. After you have the die started, don't think that the diestock has got to be revolved like a windmill. Instead of making a complete turn and bracing your foot against the bench in order to turn the die as you were doing when I came in, just try turning it a partial revolution, then back the die off and go ahead again, using plenty of lard oil. If you will try that way of cutting a thread, you won't have any trouble even with a dull die. Oil and backing the die are what count. Furthermore, don't be afraid of making the threaded end of the pipe long enough to screw well into the fitting."

"What's the difference?" asked Stetson, as he carelessly wiped his hands on a dirty piece of waste. "What's the difference so long as you get enough threads in the fitting to hold? Cutting threads is no cinch."

"For one thing, cutting a short thread is inexcusable and represents carelessness on your part, a trait that is dangerous for anyone to develop, especially an engineer. For another thing, it is almost criminal to make up a joint with but two or three threads engaging in the fittings. You can't make a joint that is to withstand steam pressure any too strong for safety, and there is the danger of a faulty joint pulling apart."

"Gee! I hadn't thought of that. One thing you said when you first came in I can't quite get through my noodle. How are you going to get a pipe thread so small that it won't fit tightly in a fitting?"

"That is the easiest thing in the world with certain kinds of thread dies. With the solid dies there is not the danger of making small threaded ends, but with the adjustable type of dies they can be so set that the pipe end is cut small, although the threads may appear to be perfect. Such a thread will not fit snugly in the fitting, and the joint is made tight only by screwing the pipe into it so far that the butt end of the thread is forced in against the outer end of the fitting." See Fig. 3.

"Such a joint, although it may hold for a time, will eventually begin to leak. This action is hastened where water is used that is of a character to rapidly corrode wrought iron or steel piping, because it has a chance to get in between the threads and act upon them. As the pipe is comparatively thin at the bottom of the threads, it does not take long for the metal to waste to a thin skin. Of course, the corroding action will be slower when the pipe carries steam, but the pipe joint will fail much sooner than if it were properly made.

"Now take my advice, cut the end off that piece of pipe and then use plenty of lard oil; and don't neglect to back off that die in making a new thread. While you are doing that, I'll toddle along home where I belong."

In cutting pipe it frequently happens that the cutters depress the pipe, reduce the area and leave ragged edges on which foreign substances gather. Do not use a nipple or piece of pipe without looking through it for blisters and obstructions, as this may save trouble later.

Turbine Speed Decreased

By E. C. Parham

A characteristic feature of all automatic governing devices is that a change must take place in the quantity governed before the governor can act to check the change and restore the governed quantity approximately to its original value. If speed is the quantity that is being governed, the speed actually must change a little in order to start the governor on its cycle of constant-speed maintenance. The governing device that most promptly responds to slight variations and prevents them from becoming heavy variations, either temporary or permanent, is the device to be desired.

The connections were checked, and found to be all right, of two 50-kw. 250-volt compound-wound direct-current generators, driven directly from two water-wheels, preparatory to paralleling them for the first time. The machines were brought up to speed and voltage, and as a final check on the polarities, the switch and breaker of one machine and the breaker of the other machine were closed, then the voltages above and below and across the remaining switch were measured with a voltmeter. As the voltages above and below the switch were equal and the voltage across the switch was zero, the proper condition for paralleling was insured. A moderate load then was put on one machine and the switch of the other machine closed, thereby placing the machines in parallel. They divided the load fairly well at first, but there soon appeared a tendency of first one machine and then the other to take most of the load. Speed variations of the turbines was evident, and on throwing on a much heavier load, the speeds dropped way down and the governors tripped out the turbines.

Investigation disclosed that the oil system of the governors was full of bits of thin paper that clogged the governor parts so that they could not function properly. Before satisfactory operation could be secured, the whole oil-piping system had to be disconnected and cleared of the paper that came from no one knew where.

Some Tall Chimneys

What is claimed to be the tallest chimney in the world, at Sagonoseki, Japan, is made of concrete and is 570 ft. tall and is on a hill 430 ft. high. It is 26¼ ft. inside diameter at the top and 42 ft. at the base. The foundation is 95 ft. in diameter and contains 2700 cu.yd. of concrete. For 150 ft. the chimney is reinforced by a concrete lining, separated from the outer concrete shell by a 5-ft. air space. In the construction of the chimney 400 tons of steel was used. The one next highest is in Montana, 506 ft. Others are as follows: At Port Dundee, Scotland, 488 ft.; Townsend, Glasgow, Scotland, 454 ft.; Freiburg, Saxony, 453 ft., on hill 259 ft.; Mechernich Lead Mining Co., 440½ ft.; Tennant & Co., Glasgow, Scotland, 434 ft.; Crossley's, Halifax, England, 381 ft.; Metropolitan Street Ry. Co., New York City, 353 ft.; Omaha & Grand Smelting Works, Denver, Colo., 350 ft.; Fall River Iron Co., 350 ft. The American Smelting and Refining Co. is constructing a chimney at Tacoma, Wash., that will be 420 ft. high.

Exhaust Steam Waste

CONSERVATION, the keynote these days, looms up morning, noon and night. It is conserve this, that and the other thing, all of which is the proper procedure in every field of labor and endeavor. No doubt about it.

This war will do for the American people what nothing else would have accomplished, and that is, they will be brought to the realization that they can easily do without many things that have been deemed actual necessities. It will also bring out the fact that they have left undone many things that they could have done and that they have allowed waste to go on unchecked just because no one took the initiative.

For weeks past the newspapers have published articles dealing with the coal shortage and the necessity of saving fuel. Other items have urged the immediate development of water power, to be under Government control, in order to reduce consumption of coal for industrial and commercial purposes. Although more coal was mined in 1917 than in 1916, there is not enough to meet the demand, because of car shortage and other reasons. To overcome this shortage, manufacturers and householders have been and are being urged to economize in fuel in every way.

Has it ever occurred to the Fuel Conservation Commission that the coal consumption of the country could be cut down thousands of tons each year by simply employing a little engineering ability, whereby the steam-plant owner and the householder could be of mutual benefit to one another, and at the same time make a saving in fuel that would be astonishing?

About eighty per cent. of the heat value in every pound of coal consumed in a power-boiler furnace is allowed to go to waste through the engine exhaust to the atmosphere. In all cities there are hundreds of these exhaust pipes discharging to the air, after passing through a steam engine, steam which could be used to advantage in the adjoining buildings that are equipped only with a heating boiler. It would require but slight pipe extensions in most cases to connect these hundreds and thousands of noncondensing engines to the heating systems of adjoining properties, thus supplying their heat requirements with steam that is now going to waste. This would enable thousands of heating boilers to be shut down, and the coal that they burned would be saved and could be delivered to such plants as are in urgent need of it for power purposes.

This journal has and does favor what is termed the isolated-block central station for just the very reasons that now confront this country as a whole—the cheaper production of power, light and heat. This idea has been developed to a limited extent in the larger cities, but not by any means on such an extended line as conditions warrant and the present time demands.

In support of this contention there are steam plants that generate steam for no other purpose than to supply heat to properties not as a byproduct, but as a commercial business pure and simple. With the outlay for underground piping and upkeep there is a good profit in carrying on the business, notwithstanding the fact that the demand for steam heat during the summer months is practically cut out, the requirement being mostly for units using steam for power purposes only. We have in mind one large central station in which the reciprocating and turbine units were operated noncondensing and exhaust steam sold to customers who did away with or had not put in heating boilers.

These instances go to emphasize the fact that exhaust steam is valuable as a heating medium, and there is no dodging the fact that the lack of action to prevent the continued waste of steam is responsible for the unnecessary burning of thousands of tons of coal.

Not only would there be a saving of fuel by the steam consumer and producer getting together on the heating question, but both could make money by so doing. The steam producer would by such an arrangement get his power for practically nothing, and the consumer would obtain his heat cheaper than he could produce it himself. More than that, there would be men released from these isolated heating plants who are needed in other channels of labor.

Why not work along more practical lines, and if there are any regulations that stand in the way of utilizing waste steam, as should be done, the Government surely has the power, as a war measure, to set these regulations aside for the common good of all.

What Do I Get Out of My Society?

THIS is a question which is often asked, especially by the isolated member. He sees others rise to positions of preferment and distinction in the society and the vocation or profession which it serves and is prone to conclude that he is contributing to the emolument of a few, favored by location or influence.

It may seem to be an irritant to his discontent to tell him that the most valuable privilege that his membership in a vocational or professional society offers him is an opportunity to give, but it is a thought the consideration of which may lead to a solution of his dissatisfaction.

Such a society is, in effect, a massing of the means and endeavors of its members for the uplift of the group, for the doing of those things which can better be done collectively than individually. If the society is truly representative, if it includes the best and accepts only reputable and recognized practitioners, his acceptance into it is in itself a mark of standing and of recognition not without value. The greater the society becomes in influence, in achievement, in usefulness to the members and service to the public, in the professional and general estimation, the greater the value of his membership in it from this point of view; and it is as much his duty and privilege to aid in making it great as it is that of any other member. If everybody's interest and effort ended with the payment of his dues, the society would die from inertia.

But to the man whose professional interest is not bounded by his individual practice, membership in a live society offers the avenue for participation in the wider activities and identification with the achievements of the profession; and he will find that the dividends that he receives upon his membership will increase in proportion with his own share in the common effort. Attendance at the meetings, joining in the discussions, by correspondence if presence is impossible, the presentation of papers, correspondence with their authors, exchange of views and information with fellow-members, willingness to do committee work, activity in enlisting desirable new members will lead to an extension of one's acquaintanceship, to a recognition of his attainments, to a knowledge of his specialties, and to a standing in the society and profession commensurate with his true worth. A society that is seeking to do things is always scanning its membership list for those who can be made use of in accomplishing its purposes; and those who come forward, not in a spirit of self-seeking but of sincere interest, and take an intelligent part in the work are the ones to whom the opportunities come for greater usefulness and through it to preference and emolument.

Determination of Boiler Efficiency by CO_2 Analyses and Flue Temperatures

ELSEWHERE in this issue appears an article showing many curves, by the aid of which the boiler efficiency may be closely approximated without the use of the usual large number of instruments and without lengthy calculations. The method is to measure the average temperature of the flue gas where the gas leaves the boiler-heating surface, to analyze for CO_2 content an average sample of gas from the same source, and apply these two determinations to a chart. The flue-gas temperature and the CO_2 percentage are assumed to be the only two variable factors of boiler efficiency.

Mr. O'Neill, the author of the article, is well known to the readers of *Power*. It is hoped that the curves presented by him will be of especial value at this time, when fuel economy in the boiler room is so important to the national welfare.

The New Military Cantonments

THE magnitude of the task of building and equipping sixteen cities, each to house from thirty-five to forty-five thousand men, is not fully realized by many, and the panoramic views on another page cannot even show the entire extent of one of them, but are intended to give a general idea of the appearance of an army cantonment. Criticism of the speed and execution of the work seems entirely out of place when one of the finished cities is viewed. One camp, for example, has about eighteen hundred Government buildings, which required for their construction some fifty million feet of lumber. The military reservation is nineteen thousand acres in extent, with ten miles of crushed-stone road, thirty miles of earth road and ten miles of railroad, thirty-five miles of water mains and thirty miles of sewerage system discharging two miles from camp. Material was unloaded at the rate of one carload every six minutes, day and night, for several weeks. At one time the contractors had a force of over fourteen thousand men employed, and the weekly payroll was approximately four hundred and fifty thousand dollars.

In view of the staggering undertaking of converting a peace-loving country and people into a huge military camp and machine, the showing made in the short period of time is truly marvelous and utterly discredits the rabid croakers whose chief business seems to be giving comfort to the enemy by charging inefficiency and lack of speed in the execution of the work. The only error appears to have been in the estimated time of completion. In other words, the work has been done as rapidly as was humanly possible, all things considered; therefore there can be no criticism of efficiency in doing, but simply that insufficient allowance was made in the estimate for inevitable delays and shortage of man-power, which could not possibly have been estimated with any degree of accuracy.

It takes a pound of coal to keep about twenty-five of the small ten-watt lamps that are used in electric-sign work running for an hour. It would run only ten of the ordinary twenty-five-watt tungstens, or seven of the forty-watt lights often used in residences. Of the best of the sixteen-candle carbon lamps it would supply only about five. The two hundred to seven hundred and fifty-watt incandescent street lamps take from eight-tenths to three pounds of coal per hour each. Count up the lamps that you see burning needlessly in lighting up streets before sunset, in running Great White Ways, in decorating store windows, or carelessly left burning in your own home, and see if a substantial saving could not be made by suppression and repression, which would cause no suffering and little, if any, inconvenience.

"The doors of the Edison Company in Detroit are wide open to anybody coming with a legitimate inquiry. Come and see us. We will tell you all we know and show you anything we have," said President Dow, of the Detroit Edison Company, to the Electro-Chemical Society at its recent meeting. This is the spirit that has wiped plagues from the earth, educated the lowly, built the United States and which gets the world nearer that material and spiritual ideal that big men know must come.

Savings-bank deposits pay four per cent. interest or less and are subject to taxation. Banks sometimes suspend payment and fail. War Savings Certificates pay four per cent. and are not subject to United States, state or local taxation, netting therefore more than the usual savings-bank interest. They are the safest investment in the world and the best paying for anything like the same degree of security. Subscribe today.

The Alcohol Fuel Committee of Australia, St. James Street, London, Eng., is looking for a good motor that will use that combustible. Got one? And this follows on the heels of the Prohibition movement!

Correspondence

Saving Coal in the Home

The editorial appearing in the Jan. 1 issue of *Power* is of interest to every reader, not because he uses coal in one way or another in producing power, but because it applies to the management of his home furnace. The idea expressed is commendable, but many of us would like to know how the one shovelful is to be saved each day with the grade of coal that is being sold at a higher price than one could buy good coal for one or two years ago.

Take my own case, for instance. Before the heating season began, the steam-heating boiler in my house was thoroughly cleaned, all leaks were stopped up, and everything was put in first-class order for heating the lower floors and the bathroom on the second floor of the house. Excepting in very cold weather, one radiator and a kitchen hot-water tank, the water in which is heated by running a circulating pipe through the boiler furnace, will comfortably heat four downstairs rooms.

There is no use in carrying a fire so low that steam will not be generated; if so, the fire is practically banked and the fuel is being burned without heating the house. Therefore it is necessary to carry a fuel bed thick enough to maintain a steam pressure, and with automatically controlled dampers the steam pressure is kept practically constant. Coal is put on the fire morning and night and at no other time, excepting in very cold weather.

Shaking down is stopped as soon as a spark of live coal drops into the ashpit, so very little coal gets into the ashes. However, it is taking more coal to heat the house this winter than it has before, and there is a reason. Judging from the coal that I have been able to get, the slate pickers at the mines have either struck, gone to war or are asleep on the job. Nobody but a blind man would allow the amount of slate to get by that I have bought, unless it was purposely done. More than that, the coal contains an excessive amount of ash, which, together with its slate content, reduces its heating value to a low standard.

If manufacturing and power plants are getting as low a grade of coal at a price equal to or higher than they have been paying, and if it contains an increase of ash and slate over former coals in proporton to the increased refuse in the coal I am burning in my house boiler, it is no wonder that there is a shortage of cars for its transportation from the mines. In my own case it will probably require between one and two tons more coal to heat the house this year than it has previously, and if this holds good in every case, of house heating, then there will be required (using the figures in the editorial) between 15,000,000 and 30,000,000 tons more of coal to do the same heating of homes than it did in former years with good coal.

I wonder if it is not a fact that the mine operators are mining coal this year that they could not find a market for in other years when there was not such a lack of transportation and a demand for coal of any kind. There is not much economy in any direction in transporting coal to market containing from 30 to 40 per cent. ash when the same cars could be used to carry coal low in ash, not any harder to mine and costing the same to buy as the trash that is now being sold as coal.

F. G. HIGGINS.

New York City.

Meeting the Emergency

I have read with interest the article by E. W. Miller on page 764 of the Dec. 4 issue, entitled "Meeting the Emergency," and give herewith my experiences while in central-station work, where the planning in detail what to do in case of an emergency came in good service.

The station is of about 45,000-kw. capacity and supplied all of the electrical power in one of the large cities in the East. As is usual, three classes of service were carried: The alternating-current incandescent and power circuits, direct-current incandescent and power circuits through motor-generator sets, and the city street-arc lighting.

Some time ago one of my articles was published (page 739, Nov. 19, 1912), outlining in detail a method of cleaning vertical turbine blades of boiler scale by pumping kerosene oil into the throttle while the machine was being run noncondensing. In order to save this oil instead of letting it go to waste through the hotwell, the exhaust was turned into an old feed-water heater to try to recover the oil. On the first trial this worked all right, the turbine being washed for about an hour and a quarter, using nearly seven barrels of kerosene. The machine had been shut down, when there was an explosion in the feed-water heater, due no doubt to the ignition of kerosene from spontaneous combustion, the force blowing one of the cast-iron heads off. In flying across the room, this hit the gravity lubricating-oil feed from the storage tanks, on the third floor, to the accumulator pumps. This line was located in the boiler-feed room under the boilers. The oil thus liberated spurted up under the 30- or 40-lb. pressure to the under side of the mechanical stokers, igniting and starting a blaze that soon got beyond control and drove the stoker attendants—in fact, all the help—from the boiler rooms.

The engine room was separated from the boiler rooms by a fire-wall, and at the time of the explosion we were operating a machine in the middle of the engine room. I was on the switchboard in charge of the load and was notified by the floor engineers at 4:20 a.m. that the engine room was on fire and it would be necessary to change the load from No. 3 turbine to No. 1 engine, as No. 3 was dangerously close to the seat of the fire, and a reciprocating engine would have to be put on the line because the accumulator was rapidly going to the length of its stroke and there was danger of burning the step of the turbine. The reciprocating alternator was immediately brought up to speed, thrown on the line and a load of about 5000 kw. transferred to the reciprocating engine at 4:46.

In the meantime two of our substations which carried auxiliary steam units had been notified to bring their machines to full speed and be prepared to take the maximum load that their units could carry. By this time the oil supply had been entirely lost and we were operating the reciprocating units simply with splash oil, endeavoring to keep them cool with increased water circulation on the bearing jackets.

We immediately split up the remaining load, cutting over all the direct-current district onto one of the substations, thus reducing the load on the main station. This was accomplished without a hitch at 4:50. At 5:17 a.m. the engineer on the floor notified me that the reciprocating alternator must come off the line as the oil on the governor had been lost and the bearings were heating up. This necessitated cutting out all the street-lighting load and transferring the remaining alternating-current incandescent load to another substation. The reciprocating alternator was pulled off the line immediately, thus shutting down the station.

In the meantime the engine room had become so clouded with smoke that all the oilers and engine tenders were compelled to go outside the building. The switchboard-operating room was inclosed in a glass cage, which proved to be smoke-proof, and I with my assistant was able to stick on the job, we having ready a rope as a means of sliding down to the street level from the window should the operating room become untenable.

At 5:28 all the load had been safely transferred, with the exception of the street arc lighting, to the substation, and things were running along smoothly. By 6 o'clock the direct-current load began to pick up and the current began to rise to a dangerous point on our machine, which we took care of by raising the voltage four volts on the substation steam sets, thus reducing the current, and in this way we were able to carry the entire direct-current load without interruption.

When the alternating-current load began to pick up, it was simply a question of dumping one circuit after another, thus keeping down the load to a safe limit, we having arranged, months before, just which circuits were to be pulled first should such an emergency arise.

In the meantime a fire alarm had been sounded and the engines from the city fire department responding had been able to finally extinguish a rather stubborn blaze, which lasted until about 8:30. The oil lost was replaced by an emergency call sent to a large local oil retailer, who loaded up several thousand gallons of engine and cylinder oils and sent them around on trucks. These were pumped off into the storage tanks, and at 8:55 the reciprocating alternator had been put on the line, and all the load was back on the station in normal running condition at 9:33, just five hours and 13 minutes from the time the alarm of fire was first given.

An idea of the intensity of the heat can be gained from the condition of the concrete floor slab of the boiler room directly over the spot where the fire occurred. This was warped up and cracked to such an extent that it was unsafe to walk across it until sufficient reinforcing planks had been laid to insure absolute safety.

Altogether there was a loss of 5000 gal. of lubricating oil, both cylinder and engine, besides a temporary shutdown on part of the system of five hours or less.

Needless to say, the practice of recovering kerosene by this method was abandoned from that time on, as we preferred to let it go to waste rather than run the chance of a second similar experience.

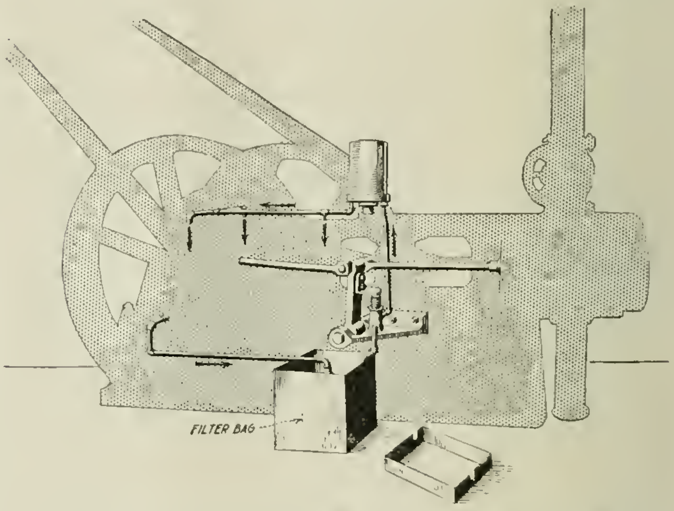
Philadelphia, Penn. MORGAN G. JOHNS.

Engine Oiling System

Engineers sometimes fail to take advantage of the opportunities they have and complain that the management is unwilling to purchase needed apparatus. Yet they could, if they would, do much to make up for the lack of equipment.

In a certain plant where the engineer is a "live wire," even though operating a plant of less than a hundred horsepower, the engine is not of the best, having given a lot of trouble because of hot bearings, etc.; but it is now doing first-rate, since the engineer rigged up a home-made oiling system for it.

The owner refused to purchase any new oiling devices, as in his estimation the power plant was only a necessary evil, so the engineer set about contriving a system of stream lubrication from odds and ends about the plant.



CONTINUOUS OILING SYSTEM APPLIED TO OLD ENGINE

For an oil reservoir he used a ten-gallon can, with a cloth bag in it, tied to the end of the return pipe to filter the return oil. By removing this bag and substituting a clean one occasionally, the circulating oil is kept reasonably clean. For a pump he used the gasoline pump taken from an old gasoline engine. This pump was driven by a bracket bolted to the rocker-arm as shown.

The elevated tank is made of 8-in. pipe and a reducer and is fastened to the engine frame with a 2-in. nipple and flange.

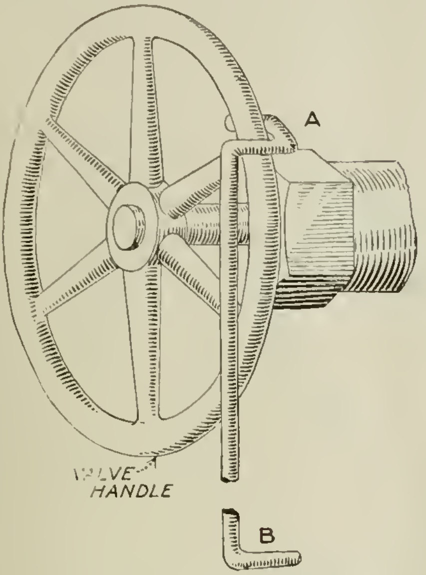
The pressure-feed lines are ¼-in. iron pipe, and worn-out valves that would not hold steam pressure are good enough to regulate the flow of oil with. A neat guard was fitted over the engine crank and did not allow the oil to splash over the floor.

It is an excellent example of what can be done with little to do with. E. S. MORRISON.

Dallas, Tex.

Operating Overhead Valves

A simple and easily made device for operating valves that are out of reach is shown in the illustration, and no other explanation seems necessary. If the valve is somewhat "stuck" or is to be closed "tight," the end *A* is used but in many cases the simple hook on end *B* will do the work. **James E. Noble.**



HOOK FOR OPERATING VALVES

Portsmouth, Ont., Canada.

Remembering Which Terminal of a Device is the Cathode

It is somewhat difficult to remember which is the cathode or anode of an electrochemical device or rectifier; that is, where the current enters or where it leaves the device. A professor, in a talk sometime ago, gave an example that is very easy to remember.

He had a cat that could open a screen door and go out, but could not open it to enter. By thinking of "cat-hole," the cat going out, it was easy to remember "cathode," the terminal at which the current left the device. Of course, if this is the cathode, the other terminal must be the anode. I have found it very easy to remember the difference between the cathode and anode since hearing this illustration.

Philadelphia, Penn. **W. H. Nostan.**

Engineers and Their Wages

I must say "A Union Engineer, Somewhere in Connecticut" on page 638 in the issue of Nov. 6, has learned the same lesson that I have; namely, that while the union scale is not fair to all, it is a good thing for the large majority. We cannot all get chiefs' jobs and their pay, but we can get lots of jobs requiring intelligent operators and through the union can get good pay. In the plant where I am we get $4.75 per day of eight hours and the firemen get $4.25 for eight hours. In the other plants outside of the union they work ten hours for $3.50 and $2.75 respectively.

Somewhere in Washington. **A Union Engineer.**

Lubricating Corliss Valves

A Corliss engine "groaned" and the valves would stick so badly at times that the dashpots could not pull them shut, although the amount of oil that was fed was "outrageous."

The oil pump was piped to feed over the ends of the valves in the usual way, but after changing the piping to feed into the steam pipe just above the throttle, there was no further trouble and the amount of oil required was greatly reduced. **N. C. Gleason.**

Northport, Wash.

The Use of Electric Hoists at Coal Mines

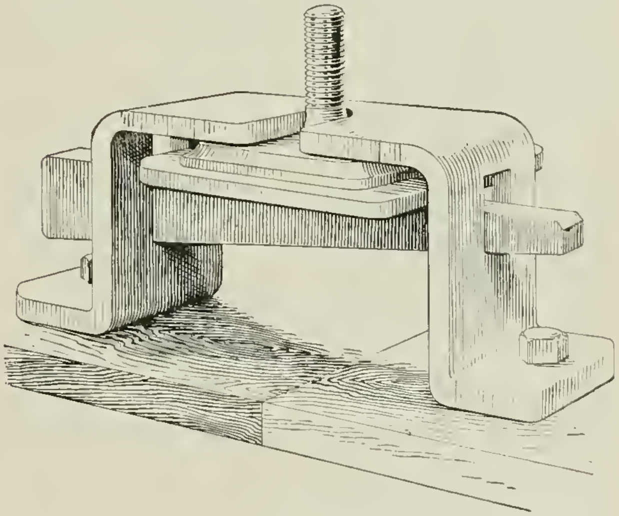
I would like to hear from readers of *Power* who have had experience with electric hoists at coal mines in Illinois, as to their reliability and economy over steam hoists, and under what conditions it is better to install an electric hoist in preference to a steam hoist.

It would also be of interest to know why one type of hoist is preferred over another, from the operating engineer's standpoint. **W. F. Decker.**

La Salle, Ind.

Bench Clamp for Handhole Plates

It has been customary when cleaning our B. & W. boilers to have a couple of men run dies over the studs of the handhole plates, because when replacing the plates, if a nut is not easily screwed home, the plate will be thrown out of position and the gasket misplaced; so it is desirable that the nuts work freely. Ordinarily, two bench vises were kept busy for this work, and often someone wanted to use one of the vises, and the work was temporarily stopped. The illustration shows a special vise, the use of which has reduced the time on the 2000 plates for two boilers from twelve hours to nine hours.



BENCH CLAMP FOR HANDHOLE PLATES

Perhaps this kink may be of assistance to some other fellow who has a lot of handhole plates to take care of. **Charles H. Willey.**

Concord, N. H.

Necessity of Air-Gap Gaging in Induction Motors

Most of the troubles arising in the use of induction motors are caused primarily by the failure of the operator to keep the air gap between the rotor and stator uniform. Consequently, if this point is carefully attended to, many delays and considerable rewinding expense will be avoided.

At the time an induction motor is placed in operation there is usually furnished a thin steel gage which should pass freely between the rotor and stator at any point. The gage is used during the installation and then probably lost or thrown away. After months or even years of operation the motor begins to heat; later, if not given proper attention, it may begin to smoke and if not attended to promptly will burn out the windings or otherwise be seriously injured.

When the air gap becomes uneven, owing to the bearings wearing down in an induction motor, the current consumption increases, the starting torque is decreased and the machine begins to heat. If these conditions are noted and properly diagnosed, the bearings will be replaced or adjusted and the motor becomes as good as ever; but if not, the condition grows worse until a shutdown results.

It is obvious that all repairs should be made before they are absolutely necessary; in other words, when they can be made at the convenience of the operator. Therefore it is good practice to use an air-gap gage periodically to determine the clearance between the rotor and stator. If this is done, the necessity of new bearings or adjustments becomes apparent before the motor efficiency is seriously impaired or abnormal current flow has injured the windings. By following this method the gain in efficiency of operation and in economy of repairs will much more than offset the cost of the additional bearings that may be necessary.

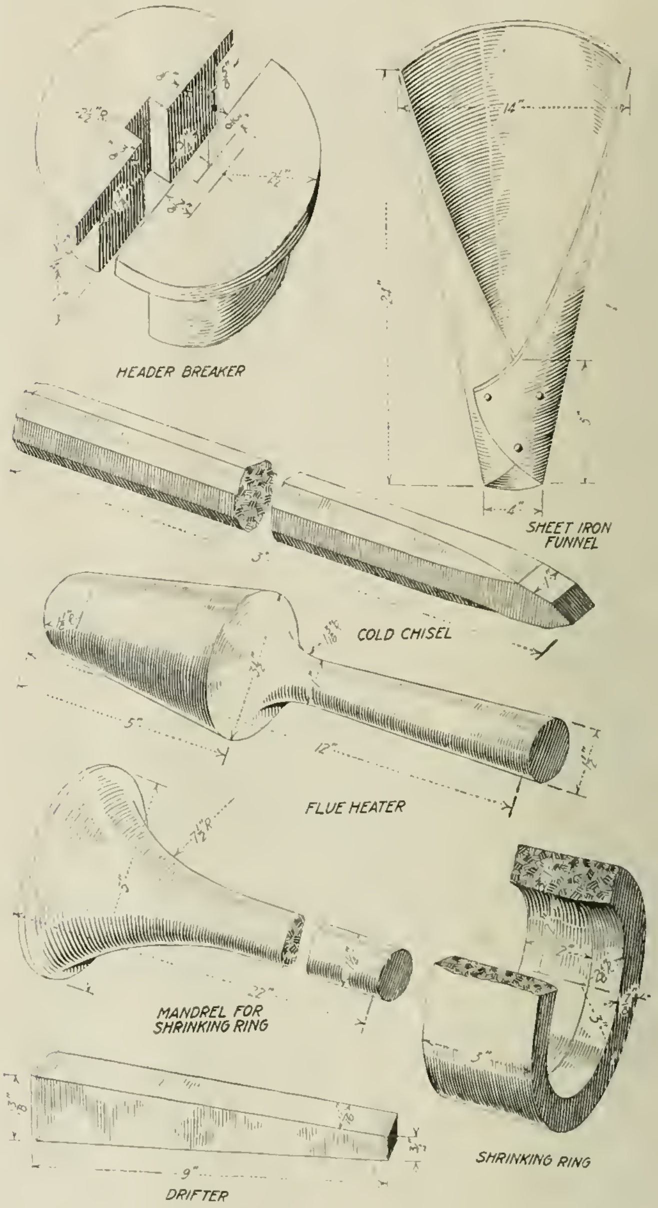
Johnson City, Tenn. D. R. SHEARER.

Replacing Boiler-Tube Headers

We have at our mine several B. & W. boilers with cast-iron headers, and after a boiler has been shut down for cleaning, on starting it up again we sometimes find a cracked header. This we think is due to unequal contraction or possibly expansion, as we have never had a header fail while under pressure. In the iron mines, as a rule, the boiler plant is worked to its full capacity with no spare boilers, every one being in use; so when a cracked header is found, it means a "hurry-up job" to get it back in service.

After making a great many different kinds of tools to remove a broken header without removing the tubes, we have adopted the set shown in the illustration and proceed as follows:

All the caps are removed from the header, then the header breaker is put in and the tapered drifter pin driven in the square hole in its center until the header breaks, the operation being repeated at each handhole. Then with the long chisel any pieces that cannot be drawn over the end of the tube are broken up. The next operation is swaging the flared end of the tube back to its original size, which is done in the following manner: The flue heater is heated in a portable blacksmith's forge, or it may be heated in the furnace of another boiler. When hot, it is placed on the inside of the tube end and to increase the heating effect the sheet-iron funnel filled with burning oil-saturated waste is hung on it, and the tube will soon be brought to a red heat. The tube-shrinking ring is then placed over the tube and the mandrel used to force the ring on by striking it lightly with a hammer; this quickly reduces the tube to its original size. Then wood blocks are placed between the tubes to keep them the right distance apart, and all is ready to put in the new header. If the job is done in this way, no new tubes are required.



TOOLS FOR REMOVING BROKEN TUBE HEADER

THOMAS J. PASCOE.

Norway, Mich.

It would help the fuel situation a bit if the street lamps in American cities were turned on when it grows dark enough to need them and not three-quarters of an hour before that time each day.

Inquiries of General Interest

Steam Required for Atomization of Fuel Oil—For atomization of fuel oil, what quantity of steam is required per pound of oil atomized? B. H. D.

The steam required to atomize the oil varies from 0.3 to 0.7 lb. per pound of oil. The average consumption is about 0.5 pound.

Overheating of Clean Water Tubes—What causes burning, bagging or blistering of tubes of water-tube boilers below the water line when the tubes are made of good material and clean of oil and scale? J. T. M.

A water tube may become burnt, bagged or blistered when, from forced firing or poor circulation, the water of the boiler is driven or held away from the tube surface by the steam that is generated, thus permitting the tube to become overheated.

Setting Steam Valves of Duplex Pump—What is the simplest method of setting the steam valves on a duplex pump? W. N.

Place both pistons in the center of their travel; the rocker arms will then be plumb. Remove the steam-chest cover and place each steam valve centrally over the ports, and adjust lost motion equally on each side of the collars or nuts that move the valves. Before replacing the steam-chest cover, move one of the valves so as to open a steam port and thus enable the pump to start up when steam is admitted to the steam chest.

Holding Safety Valves During Hydrostatic Test of Boiler—The pop safety valve of a boiler is set to blow off at 100 lb. pressure. What should be done to the valve so as to obtain a test pressure on the boiler of 150 lb. per square inch? B. B. T.

During a hydrostatic test the safety valve or valves of a boiler should be removed with the connection temporarily blanked off, or each valve disk should be held to its seat by means of a testing clamp. Most manufacturers of spring pop safety valves furnish a special testing clamp, or "gag," for the purpose. The valve should not be held closed by screwing down the compression screw upon the spring, as that would be likely to injure the spring.

Kilowatt Output of Alternator—What is the actual kilowatt output on an alternator when the ammeter reads 300; power-factor meter, 0.82; and the indicating kilowatt meter, 1360? W. C. C.

The ammeter reading and the power factor are not necessary to be taken into account, as the kilowatt output of the machine is that registered by the kilowatt meter; namely, 1360. If the number of phases and voltage were given, it would be possible to check the correctness of the meter readings. For a two-phase machine the kilowatt output is equal to volts per phase × amperes per terminal × 2 × power factor ÷ 1000; and for a three-phase machine the output would be volts per phase × amperes per terminal × 1.732 × power factor ÷ 1000.

Size of Conductors for Two-Phase Motor—How is the size of the conductors, 200 ft. long, determined for a two-phase four-wire 50-hp. 220-volt motor? I. C. B.

The full-load current required per terminal by the motor is generally given on the name-plate, but can be determined approximately by the expression, hp. × 1000 ÷ volts × 2, in this case amperes = 50 × 1000 ÷ 220 × 2 = 114. The National Board of Fire Underwriters' Code states that the carrying capacity of conductors for alternating-current motors requiring over 100 amp. per terminal must be 150 per cent. of the normal full-load current rating of the motor; in this problem, 114 × 1.50 = 171 amp. For a rubber-covered conductor the wire table gives a No. 000 B. & S. as the correct size. This size conductor for alternating-current motors can be fused up to the rating for other insulations or 275 amp. The resistance of 400 ft. of No. 000 copper wire is 0.025 ohms, and the volts drop in the line at 50 per cent. overload is, current × resistance = 171 × 0.025 = 4.3 volts, which is well within good operating practice.

Short-Circuit Secondary of Current Transformer—Why is it necessary to short-circuit the secondary terminals of a current transformer when they are disconnected from the device the transformer is serving? E. K. P.

The iron core of a current transformer under normal conditions is worked at a very low magnetic density, consequently the flux will build up very rapidly as the ampere turns increase, if their effect is not neutralized in some way. When a current transformer is under normal load, the ampere turns in the secondary are almost equal to those of the primary, therefore the effective ampere turns, and likewise the flux and voltage, are at a low value. However, if the secondary circuit is opened, when the transformer is loaded, the total primary ampere turns are effective in setting up a flux, which reaches a high value, likewise the voltage in the winding. The latter in many cases become of a value that will break down the insulation and destroy the transformer. A current transformer operating with its secondary open-circuited also acts as a choke coil in the line. By short-circuiting the secondary terminals, when they are disconnected normal conditions are maintained in the transformer.

Heating Feed-Water at Expense of Back Pressure—In a steam plant operated at 100 lb. boiler pressure, a closed type of exhaust-steam feed-water heater delivers the boiler-feed water at 205 deg. F. with 2 lb. back pressure on the exhaust of the engine. Would it not be more economical to raise the temperature of the feed water to 212 deg. F. by increasing the back pressure on the engine? W. C. C.

If the only heat recovered out of the exhaust is that utilized by the heater in raising the temperature of water required for generation of steam supplied to the engine, then it would be detrimental to economy to increase the temperature of the feed water at the expense of increasing the back pressure. The temperature of the exhaust at 2 lb. back pressure above the atmosphere is about 219 deg. F., and to increase the feed-water temperature to 212 deg. F. or 7 deg. higher would require the exhaust to be at a temperature of about 226 deg. F. corresponding with about 4.5 lb. per sq.in. above the atmosphere, or an increase of 2.5 lb. back pressure; and with the same load the consumption of steam by the engine will be increased practically as though the load had been increased to require 2.5 lb. additional m.e.p. Allowing the required m.e.p. to be 50 lb. per sq.in., the increased steam consumption would be about 5 per cent. A pound of steam at 100 lb. gage, or 115 lb. absolute, contains 1188.8 B.t.u. above 32 deg. F. and generated from feed water at 200 deg. F. requires 1188.8 + 32 — 200 = 1020.8 B.t.u. With the feed water at a temperature of 212 deg. F. obtained with 4.5 lb. back pressure, each pound of steam generated would require 1188.8 + 32 — 212 = 1008.8 B.t.u.; but 1.05 times, or 1008.8 × 1.05 = 1059.2 B.t.u. would be required for performance of the same work as obtained from a pound of steam with only 2 lb. back pressure, so that increasing the back pressure to raise the feed-water temperature from 200 to 212 deg. F. would be attended by requirement of (1059.2 — 1008.8) × 100 ÷ 1008.8 = 4.9, or practically 5 per cent. more fuel for developing the same power.

Preventable Waste of Coal in the United States*

BY DAVID MOFFAT MYERS†

By employing proper operating methods in boiler plants it is easily possible, according to the author, to save at least 10 per cent. of the coal now burned for steam-making purposes. Such a saving would release cars for other service equivalent, say, to the coal-carrying capacity of the Pennsylvania Railroad lines east of Pittsburgh, equal to 1,000,000 fifty-ton carloads per year, and the direct money saving to the industries would be around a quarter of a billion dollars, figuring the coal at $5 a ton. Discussion on the paper appears in this article.

As a means of far-reaching economy the Government of the United States should at this time apply intelligent and direct-acting efforts to the conservation of fuel at the industrial plants which are responsible for its greatest consumption.

The mining and distribution of the coal have been placed under the supervision of the War Coal Board in order more nearly to meet the crying needs in these directions, to use the railroad facilities more efficiently so that the present car shortage may be minimized and to apportion the coal in quantity and to uses deemed most expedient.

While this organized effort to bring about efficiency in the production and distribution of coal is being made, no parallel measures have been adopted to bring about a normal and practicable efficiency in its use. The hundreds of large plants which are consuming fuel wastefully, in many cases more wastefully and carelessly than ever before, are directly and needlessly causing a large fraction of the existing car shortage.

PREVENTABLE WASTE OF FUEL

The preventable waste of fuel in the boiler furnace of one steel mill which I investigated amounted to 40,000 tons per year, which at $5 a ton would cost $200,000. This was a comparatively modern plant. The efficiency of boilers and furnaces in a 14-day test was 55 per cent. The load factor was unusually favorable to high efficiency and could readily be raised to 70 per cent. or over. This is only one example, and there are many more extreme cases. In one hand-fired plant the evaporation was raised from 6 to 9 lb. in a few days of instruction and continuously kept close to this higher mark with the help of coal and water measurements which were inaugurated. The saving was due exclusively to instruction and consequent better operation.

The saving or wasting of one-fourth of the coal consumption of any industrial plant depends entirely upon the efficiency of its operating management. Let me emphasize that this fraction of the consumption relates exclusively to the *boiler* plants, that is, the production of steam, and does not include the large economies possible in connection with its distribution and use.

For well-known reasons the boiler plant offers the more lucrative field for producing economies, and these with a minimum of alteration in physical equipment.

Under present conditions a plant which carelessly operates at an efficiency of 40 to 50 per cent. receives from the Government the same consideration in the delivery of coal as the one whose efficiency is 70 to 75 per cent. This obviously is unfair and wasteful.

The Government hands over, say, 200,000 tons of coal a year to a plant owner, but asks for no accounting as regards its consumption, nor any questions as to the amount of steam it is made to produce.

There is no doubt that very important economies in the use of food have already been effected by educational campaigns. These economies are largely the result of educating the ultimate consumer. The requisite propaganda does not attempt to teach the intricacies of food chemistry or the complex action of the gastric juices.

The object of this paper is to open a discussion which, it is hoped, will ultimately lead to the formulation of definite fuel conservation recommendations, to forward these recommendations to the proper governmental authorities as an official communication of this society, and to offer to the Government the services of the society for the organization, furthering and, as far as possible, the execution of the plan which may as a consequence be adopted.

There are, I think, two plans of operation worthy of consideration. The one might be termed the autocratic method. This would involve the use of authority to compel coal consumers to execute such measures of economy as the proper authorities might prescribe for any given case, limits to be set as to expense to the user. Such limits might be in terms of a percentage of his present yearly coal bill. Alterations should be directed chiefly, as previously implied, to purely operating improvements. Many objections would probably be made by consumers against this plan, but once in effect the majority would no doubt realize its pecuniary advantage to themselves. But its tendency may be too strongly opposed to democratic principles.

The other plan would be largely an educational one, in which patriotism and efficiency would furnish the motive forces required. The teaching must be accomplished with the utmost simplicity and directness. Above all it must be in such form as to be readily comprehended and applied.

The requisite information must reach the owners and managers of industries, and there must be simple instruction sheets for the engineers and firemen. The vital importance of daily accurate records of coal and water must be taught and information given regarding practical appliances for automatic measurements of both.

Blank forms might be sent in advance to plant owners in order to be advised by them, first, whether they would be willing to coöperate with a governmental organization offering to assist them in reducing their coal consumption, and second, to obtain such data as to size, type, equipment, operation and fuel consumption of the plants as would enable a classification that would permit a government board of experts to send such instructions as would include the information needed for any one class of plants.

This work would be very greatly aided by a staff of experts ready to visit plants when so requested by owners, and make investigations and recommendations and keep in touch with the progress of economies. Included in such a staff must be men intimately familiar with practical operating economies, whose duties would be the delivering of lectures or talks which should be planned so as to reach directly not only managers and owners of the industries, but also the chief engineers and firemen of the boiler plants.

TABLE I. TOTAL COAL PRODUCTION, BITUMINOUS, LIGNITE AND ANTHRACITE, YEAR 1915

		Net Tons	Per Cent.
1.	Bituminous and lignite	443,462,509	85.2
2.	Anthracite	76,906,431	14.8
3.	Total	520,368,940	100.0

The United States Bureau of Mines has for a number of years engaged in obtaining and disseminating scientific information regarding the mining and consumption of coal, and the results of the work have been of great value to technical engineers who are able to use and apply it.

Six hundred million tons of coal was mined in the United States last year. It is predicted that 700,000,000 tons will be mined this year, and next year's production will likely be still greater. Of this quantity approximately 67 per cent., or 469,000,000 tons, will be burned for steam-making

---

*Presented at the annual meeting, December, 1917, of the American Society of Mechanical Engineers, New York.

†Consulting engineer, New York City.

purposes on land, assuming the same percentage consumption for steam production as existed in the year 1915.

The saving or wasting of one-quarter of this coal, that is, over 117,000,000 tons, depends on the efficiency with which we operate our boiler furnaces. If we actually saved by proper methods only 50,000,000 tons per year, this economy would result in freeing for other important service the use of 1,000,000 fifty-ton freight cars per year. The significance of such an economy may be realized when it is stated that the number of cars thus released for other service would be equivalent to 15 per cent. more than the combined yearly coal-carrying capacity of the Baltimore & Ohio and Southern Railway systems; approximately equal to that of the Pennsylvania R.R. system on lines east of Pittsburgh, or 1⅝ times the number of coal cars hauled by the Norfolk & Western. The direct saving to our industries would be $250,000,000 worth of coal per year, if figured at $5 per ton.

TABLE II. PERCENTAGE DISTRIBUTION OF BITUMINOUS COAL AND LIGNITE PRODUCED IN THE UNITED STATES AND IMPORTED IN 1915, BY USES

		Per Cent
1.	Railroad fuel	28.0
2.	Steamship bunker fuel—tidewater	2.0
3.	Steamship bunker fuel—Great Lakes	0.3
4.	Manufacture of beehive coke	9.3
5.	Manufacture of byproduct coke	4.3
6.	Manufacture of coal gas	1.0
7.	Domestic and small steam trade	16.0
8.	Industrial steam trade	33.0
9.	Exported	4.0
10.	Steam and heat at mines	2.0
11.	Special uses	0.1
12.	Total bituminous and lignite	100.0

NOTE.—Imports were only a little over one-tenth of one per cent. and are therefore neglected.

No information is available for complete classification of the distribution of the anthracite, but it is estimated in report on "Coal in 1915"* from which Tables I and II are made, that 50,000,000 net tons of anthracite were used in 1915 for "heating households, apartment houses, hotels, and office, school and other buildings." This leaves about 27,000,000 net tons or 35 per cent. for industrial uses, principally steam making. If we eliminate households we may assume that 25,000,000 tons of the 50,000,000 tons are used for making steam, so that of the total 77,000,000 tons of anthracite we may say that 52,000,000 tons, or 67.5 per cent. are used for steam production.

* "Coal in 1915," by C. E. Lesher, published by the U. S. Geological Survey; Part A on production, Part B on distribution.

This saving would be $\frac{50,000,000}{469,000,000} = 10.65$ per cent. of the coal now burned for steam production. It is impossible to state the present average efficiency of boilers and furnaces, but I have personally spent sixteen years of concentrated study in the investigation and improvement of steam and fuel conditions in factory power plants, and I have never visited a plant of this class where a saving in coal of at least 10 to 12 per cent. could not easily be made. The poorer the conditions found the easier it is to make an attractive saving in fuel.

Table IV shows to what point the efficiency of a plant must be raised to obtain the saving of 10.65 per cent. upon which these economies are based. The poorly run boilers would of course be susceptible to the greatest improvements. Hundreds of boiler plants operate at no greater than 58.07 per cent. efficiency, and it is a comparatively simple matter to bring them up to an efficiency of 70 per cent. or higher. The latter would result in a saving of over 17 per cent. of the coal.

TABLE III. COAL USED ON LAND FOR STEAM PRODUCTION IN PERCENTAGE OF TOTAL PRODUCTION

		Per Cent
	Bituminous:	
1.	Railroads, item 1, Table II	28.0
2.	Domestic and steam trade, assume only one-quarter of item 7, Table II	4.0
3.	Industrial steam trade, item 8, Table II	33.0
4.	Steam and heat at mines, item 10, Table II	2.0
5.	Total bituminous	67.0
	Anthracite:	
6.	To steam making	67.5

Hence it may be assumed that 67 per cent. of all the coal produced is used for making steam on land.

To save 10.7 per cent. of the coal consumption necessitates the raising of any combined efficiency of boiler and furnace from that shown under Old Efficiency in Table IV to the corresponding value under New Efficiency in the same table.

If we do not limit our action to coal used for steam generation, but extend it to include economy with which the steam itself is utilized and applied, the predicted saving could be doubled, so that we might save 2,000,000 fifty-ton carloads of coal per year. There is, for instance, widespread ignorance to a surprising degree in regard to the value of exhaust steam in heating and process work. The coal-consuming public should be taught that a heating system which requires 100 boiler horsepower may insert a steam engine between boiler and heating main and obtain nearly 100 mechanical or electrical horsepower in addition to the required heating for about the same consumption of fuel.

TABLE IV. INCREASES IN COMBINED EFFICIENCIES OF BOILER AND FURNACE NECESSARY TO EFFECT A 10.7 PER CENT. SAVING IN COAL

Old Efficiency, Per Cent.	New Efficiency, Per Cent.	Old Efficiency, Per Cent.	New Efficiency, Per Cent.
44.67	50	62.54	70
49.14	55	67.00	75
53.60	60	71.47	80
58.07	65		

Saving of coal with same output of steam

$$= \frac{\text{New Efficiency} - \text{Old Efficiency}}{\text{New Efficiency}}$$

and

Increase of steam production for same coal

$$= \frac{\text{New Efficiency} - \text{Old Efficiency}}{\text{Old Efficiency}}$$

Steam plants are under the immediate management of chief operating engineers. The examination requirements for licenses in this profession call for practically no knowledge of steam and fuel economics. These examinations deal chiefly with matters of safety, repair and maintenance of equipment and neglect almost entirely the subject of coal economy. This is a very serious defect in our present system and is directly responsible for a large preventable waste of fuel.

The mining and distribution of our coal supply, the regulation of prices and the adjustment of financial and labor problems have already been placed under official administrative attention. But no parallel measures have been adopted looking toward reduction of waste in connection with the utilization of this coal.

DISCUSSION OF THE PAPER

Walter N. Polakov: The invitation to discuss the means and methods for reducing waste of coal is very welcome since all that has been said and done so far has failed to produce tangible results.

Last April I brought out the impending danger of a fuel famine and soon afterward the movement was on the way affecting at that stage only coal production, transportation and prices.

Being limited in its scope and nature, it did not embrace at that time the third group of my original recommendations concerning the use of fuel. My editorial in *Coal Age* of July 14 and articles in other magazines[1] emphasized this paramount task "to start at once the movement for the efficient utilization of every available supply of fuel."

A couple of months later Mr. Garfield publicly admitted that the principal hope for a solution of the coal problem lies with the people themselves: "They must save every possible bit of fuel."

Saving may be carried out along two lines—either on the principle of German "Spar Kasse," inevitably limiting the industrial productivity and impairing the health of the people, or on the principle of more efficient utilization of fuel, producing more power and heat with less coal. Only this latter means of saving is to be considered.

The inauguration of efficient management of power plants cannot be accomplished overnight. It requires study in each plant of its peculiar conditions. It requires careful training of firemen and other employees. It necessitates an adequate stimulation of employees to continually maintain the highest degree of efficiency. To do it no capital investment is needed. It is not a matter of better furnaces, of mechanical stokers, or other cures preached by salesmen. It is a matter of knowledge and method.

There are already many plants that have reduced their coal consumption from 20 to 40 per cent. for the same output, by better organization of power-plant work. There is no need to here describe these principles and their results. "Task Setting for Firemen," a paper presented before this

---

[1] "Industrial Management," May, 1917, September, 1917; "Literary Digest," June 15, 1917; "Utilities Magazine," September, 1917.

society in 1913, "Planning the Power Plant Work," a paper delivered before the Taylor Society, and numerous other contributions describe the nature of my work and fundamental principles more or less at length. Van H. Manning, Director of the Bureau of Mines, recently took the view advocated by me for years. Said he: "The immediate problem is a difficult one. We cannot scrap all out-of-date power plants. We must start by doing the best with what we have. We must begin saving coal at once. The problem is a personal one. It deals with the human elements. We must reach the man with the shovel."

Mr. Myers presents for discussion two plans. The first one is unfortunately worded so as to create prejudice against it. It reads ". . . . the use of authority to compel coal consumers to execute such measures of economy as the proper authority might prescribe in any given case." It sounds Prussian. But is it? Does it mean imperialistic, arbitrary authority or an authority of an expert based on scientific knowledge of facts, similar to the authority of a doctor prescribing treatment?

The strength of England, France and even the Central Powers is due to the coöperation in industries. Those who fail to render the service to the common cause are denied the privilege to mismanage their plants. True enough, this coöperation is regulated by the state and at times compulsory as is conscription or commandeering of productive facilities or commodities. The voluntary coöperation for which we long will come only after the war as a result of new social readjustments. But we cannot wait. The problem is of today. Tomorrow may be too late.

In other words we must create conditions stimulating voluntary coöperation even under individualistic regime.

The plan therefore means the abolition of privilege to waste fuel in inefficiently conducted plants, by giving priority in coal deliveries to those who prove that they do not use it efficiently.

At present a wasteful plant gets an excessive amount of coal, while the highly economical one stands an equal risk of being shut down for the lack of coal. If the efficiency is protected by priority, it will work also as a stimulus for the wasteful ones to find means to improve their methods and then ask for a new rating.

Such encouragement of efficient plants, rendering good service to the country and stimulating the inefficient to seek their salvation through the means beneficial to the country can be accomplished along the following lines:

Rating by experts (nominated by the national engineering societies and supported by public opinion and Government) of plants in the indispensable industries who are entitled, because of coal-saving methods in use, to the priority in coal supply.

Receiving of applications by the special service bureau of American Society of Mechanical Engineers, from the low-rated plants for assigning the expert help.

Serving the needs of such inefficient plants by offering services of recognized experts in power-plant management for direction of the work.

Organizing a staff of steam, electrical and combustion engineers, whose members will be assigned to carry out the work in the plants of the applicants under the direction and supervision of experts.

Charging for such services an adequate compensation to cover the expenses involved (salaries, traveling and office) but no profit.

Mr. Myers' second plan, "an educational one, in which patriotism and efficiency would furnish the motive forces required," is in my opinion doomed to failure for the following reasons:

Teaching efficiency by a correspondence-school method will accomplish little good, is incompatible with the professional dignity of this society and lacks the personal touch.

Endless variety of equipment, grades of fuel available, personality of men, nature of load, climatic conditions, etc., make the preparation of "simple instruction sheets for engineers and firemen" impossible and if made they are so general as to be useless. Failure of the Massachusetts fuel board in such an attempt is a joke among power-plant men in that section.

No instructions of real value could be given unless examination of the plant was made. Selling patent medicines curing all diseases ranks with fake only too often not to make one careful.

Keeping records, logs, etc., necessitates instrument equipment and measuring devices; all of this is good only when the data are used and interpreted by a trained man and this is done continually. Too many plants have no instruments at all; most of those that have, keep them as ornaments owing to the lack of proper organization.

If the regular employees failed to secure high efficiency it is not because of the lack of "circularized education" but chiefly on account of lack of time to carry on investigations and tests all the time being absorbed by routine duties; absence of instruments, facilities or encouragement; lack of experience in this highly specialized line of research work.

The education must begin with owners and managers, not with the firemen.

The very principle of "teaching" and "instructions" given to manufacturers and plant owners by the society is undemocratic and unamerican. They do not want or need "to get something for nothing." Producing for the country but not without profit they can prefer to pay for what they get if the benefit is commensurate with the expenses.

"Educational" talks and circulars usually degenerate rapidly into debating societies, wasting time needed for deeds.

Any half-measures with good intentions falling short of accomplishing valuable results are dangerous as they chloroform the public conscience, creating a belief that something real is being done while there is little behind the words that make all content.

To sum up, the problem is to be solved by groups and individuals availing through this society to the services of those who know how more power can be gotten out of a pound of coal. There is no necessity to compel plant owners to improve their methods since in such a step lies their self-preservation. But there is an urgent necessity from the national viewpoint to conserve the fuel by preventing its waste by ignorance or indifference. The valuation of plant methods to establish ratings for priority in coal deliveries is therefore recommended.

Albert A. Cary: Mr. Myers endeavors to focus our minds upon this panacea in the statement that "the saving or wasting of one-fourth of the coal consumption of any industrial plant depends *entirely* upon the efficiency of its operating management," and this seems to be the text upon which the balance of his paper is founded.

To secure the desired conservation of fuels in such plants, Mr. Myers advises the services of the expert in operating management. Provided he understands his business, such an expert can undoubtedly secure desirable fuel savings; but results depend largely upon the coöperation he receives from the plant owners and their employees, as well as their willingness to equip plants with the needed apparatus and to use them continuously after the expert concludes his work.

To illustrate, I will refer to the plant of one of my clients, the Tennessee Copper Co. By redesigning the furnaces in this plant and adapting them to the fuel used and by substituting machine-fired grates, they have since succeeded in obtaining the same amount of steam with but 64 per cent. of the Jellico coal formerly used. This plant, when completed, was turned back to the same management that it had before with no further instructions. There were installed facilities for continuously determining the weight of the coal, ash and water used as well as the analysis of the furnace gases.

In another large industrial plant a similar saving in coal was effected. This plant has an aggregate capacity of over 7000 nominal boiler horsepower, divided into 22 units. It was formerly operated with hand-fired shaking grates for which machine-fired grates were substituted with properly designed furnaces. The plant is now being operated continuously at 150 per cent. rating and is using no more fuel than it formerly did when being operated at two-thirds of its present output. The boiler-room force required to operate this altered plant is less than half of the number of men formerly required. No change has been made in the management of this plant.

Proper furnace design and construction, flue and draft-producing equipment adapted to the use of the particular kind or quality of fuel used is the keynote of the question of fuel conservation.

Furnish the mason with complete instructions for "laying up" the brickwork and properly bonding the interior and exterior walls of the furnace so that the large difference in temperature between the two sides will not, by unequal expansion and contraction, rapidly destroy these furnace inclosures and so waste fuel by infiltration of air.

The selection of material used and its method of erection should never be left to the mason, as it is safe to say that fully 90 per cent. of the masons erecting furnace settings are hopelessly unqualified to produce a proper setting. After equipping the plant with proper furnace settings which are adapted to produce the highest possible efficiency with the particular fuel available, the expert in operating management can come into the plant to instruct the men.

To meet the present emergency, I propose that the War Coal Board bring all the firemen in this country under its control by requiring them to take out United States licenses. The various state, county or municipal governments can assist them in this work. The applicants for these licenses must show some qualifications that would entitle them to hold such privileges, but it is doubtful whether it would be possible, at the beginning, to have all these applicants examined before qualified examination boards.

Future applicants should be required to pass an examination before such boards and qualify in a satisfactory manner before receiving their licenses. Any operator of a coal-burning plant (domestic plants, of course, excepted) who operates his equipment without a licensed fireman should be liable, first to fines and finally to more severe penalties.

Each license should be issued for the applicant to operate in a definite, described plant and nowhere else. Should the fireman leave this plant for any good reason, rather than for incompetence, he can take his license to the proper authorities and have it transferred to another plant where he has found reëmployment.

Should the fireman be found to be incompetent, his license should be revoked and future applications be denied.

Inspectors appointed by the War Coal Board might visit from time to time the various coal-burning plants, and should they find any of them using fuel wastefully, a notice should be served upon the owner. If this is not followed by prompt action to reduce or stop the waste, the fireman's license should be revoked.

The foregoing is proposed as a war measure.

Professor L. P. Breckinridge told of the methods used in Connecticut to conserve coal, stating that meetings were held to which the public was invited, to be told how to burn coal economically in house and power-plant boilers. Norman Reinicker believed that fuel economy was much more a matter of design than education of firemen. E. N. Trump emphasized the value of bonuses to firemen to give incentive for economical use of coal.

Utilizing Surplus Electrical Energy for Generating Steam*

By F. Hoehn

An interesting test was conducted by the Swiss Society of Steam Boiler Owners to determine the commercial possibilities of generating steam for heating purposes by electricity. The plan proposes the heating and storing of the proper volume of water under pressure, from which the steam was to be generated by expansion to a lower pressure on the principle of the fireless locomotive.

A small model tubular boiler 24 in. in diameter and 50 in. long containing thirty-eight 1¼-in. steel tubes was used for the test. Glass-insulated microhm heating coils having a resistance of 1.1 ohms were inserted in 34 of the tubes and so connected that the latter were divided into three groups of 18, 9 and 7 respectively, any of which could be cut out of service. Direct current at 225 volts obtained from a hydro-electric plant on the premises was applied.

The following table gives the results of two tests:

	Test No. 1	Test No. 2
Duration, hours	7.6	7.0
D.C. voltage	225.8	225.6
Average amperes	142.4	148.8
Average kilowatts	32.2	33.6
Average pressure, lb. per sq.in. abs	25.0	29.4
Average temperature, deg. F	51.8	50.0
Total heat in one pound of steam, B.t.u.	1,160.0	1,163.4
Total evaporation, lb. per hour	85.5	89.7
Evaporation in pounds per square foot of heating surface at minimum demand	2.7	2.42
Evaporation in pounds per square foot of heating surface at maximum demand	2.85	2.68
Evaporation in pounds per square foot of heating surface at average demand	2.76	2.62
Total pounds steam generated per kw.-hr	2.65	2.67
Theoretical heat in B.t.u. per kw.-hr	3,415.0	3,415.0
Actual heat obtained in B.t.u. per kw.-hr	3,074.0	3,106.3
Efficiency, per cent.	90.0	90.9

The efficiency of 90 per cent. might have been improved by better lagging, as most of the losses were due to radiation.

It is interesting to note that the evaporation per square foot of heating surface was greatest at minimum demand, owing to the better heat transfer to the water when the latter was not filled with steam bubbles. For practical purposes it is fair to assume a mean evaporation of 2.46 lb. per sq.ft. of heating surface.

The first requisite for steam generation by electricity is a cheap source of power. In order that such a system may compete with a coal-fired plant, with coal selling at $8.75 per ton in Switzerland and an average evaporation of 7 to 8 lb., the author computes that the cost of current cannot exceed 0.16c. per kilowatt-hour.

Such low-cost current is rarely obtainable. However, cases may arise where an otherwise partly idle hydro-electric plant can be used to furnish the necessary current on nights, Sundays and holidays. If, then, sufficient heat can be stored in the water to furnish steam by regeneration for the entire week, the practical application of this method takes on an entirely different aspect.

The author derives a number of equations for computing the heating surface and the storage space required for furnishing the maximum amount of steam for heating purposes at a reduced pressure of 22 lb. absolute, with an available power supply of 883 kw. for 12 hours.

Given a feed temperature of 59 deg. F., the total steam obtained at a mean pressure of 99 lb. is shown to be 2244 lb., which would require about 80 sq.ft. of heating surface. The total amount of water necessary amounts to 20,661 lb. and would require a storage space, making due allowance for extra steam space of some 400 cubic feet.

Placing the radiation losses at 6 per cent., the total amount of steam reduces to 2109 pounds.

With an evaporation of 7.5 lb. and coal at $8.75 per ton, this represents an equivalent fuel cost of $1.23 per day, or $369 per year of 300 working days, an amount which the author believes sufficient to cover the interest and depreciation of the simple equipment required.

The system offers the advantage of high efficiency in transforming the surplus electrical energy into heat with only slight storage losses and to give up this heat at any rate desired while requiring only nominal attention. It may also become the means for improving the load factor of the plant by cutting in the heating coils as the load decreases.

---

*Translated from "Schweizerische Bauzeitung."

Heating Houses with Gas

As a producer of heat units on the generous scale for such service as house heating, manufactured city gas has not been able to compete with coal, says E. D. Milener, in *American Gas Engineering Journal*. Even with gas at 35c. a thousand cubic feet and coal at $8.50 a ton, the average fuel cost of heating an entire house with gas will be at least 25 per cent. more than with coal, and to keep this difference from being greater it is necessary that the best equipment only be used and proper attention given to its operation. A three-story cottage equipped with a gas-fired steam-heating system consumed, during the eight months from October to May, 465,800 cu.ft. of gas. The lowest monthly consumption, during October, was 23,700 cu.ft., and the highest, during February, was 88,700 cubic feet.

Engine-Room Management in the Ice Plant*

By EDWARD N. FRIEDMAN†

The author does not condemn the high-speed ammonia compressor; but believes more accurate performance data and more knowledge of how these machines "stand up" under everyday service are needed to warrant their wide and rapid adoption. Several hints on engine-room management follow.

WE HAVE not exactly been told, but it has been intimated, that anybody not using the new high-speed compressors and electrical drive or uniflow engine is a back number; that this or that certain system of raw-water ice with or without core-suckers is the only system to use; that only synchronous motors with direct drive show that a plant is up to date; that this or that filtering system does away with water softening; that this or that water softener does away with filters, etc., etc.

There are scarcely any reliable test data available as to the actual performance, and particularly as to the lasting qualities, of the high-speed compressor under various conditions. They have not been in use long enough to judge whether the claims for them are justified. I am as much in favor of progress as anybody, but I feel that far more information about actual performances must be gathered. I know that a number of plants have been installed, but not enough data have been established yet to remove all doubt that the slow-speed compressor must go. Two reasons for favoring the high-speed compressors against the old-time slow-speed are usually given; namely, the smaller space required and the cheaper first cost. I find, however, that the second reason is not in accordance with the facts. Some of the new high-speed compressors cost more than the slow-speed of the same capacity, and I cannot see why.

SEPARATE COOLING OF LIQUID AMMONIA AND WATER

One thing, however, has been done lately to a greater extent than before, and that is the separating of the cooling of the liquid ammonia and the water from the general system, using a separate compressor running under higher back pressure, which means higher economy, as I shall try to explain later. This, of course, has nothing to do with the high-speed compressor or the uniflow engine, but is the outcome of the installation of the raw water system, since without that system the question of economy is mainly a question of the boiler-plant economy.

This also refers to the question of superheaters for the steam. Since, however, we all are not ready to put in new machinery and since we have to get along with what we have, let us see how we can arrange things to get the best results out of our present plants.

Any ordinary ice plant consists of boiler plant, engine-room equipment, condenser floor and ice-tank storage room. Each of these things is important and essential to the plant, but the main question is whether these different parts are built of sizes or capacities to work with the other parts to the greatest advantage for the final purpose. There must be a certain relationship as to the size of compressors, the number of cans and amount of piping in the tanks, the size and amount of piping in the water forecooling tank and the size of the ice-storage room. Any mistake in sizes and arrangement of any one of these items means a drawback and lack of economy.

If, for instance, the size of the distilled-water storage tank is too small, it means losses of water during lunch hours. If the amount of piping in tanks is too small, it means lower back pressures to obtain lower temperatures, a decidedly uneconomical feature; if there are not sufficient cans, the same argument holds good; if the condenser capacity is too small, it means higher condenser pressure and higher power consumption per unit of output, whether steam, electrical or any other kind.

If the storage room is too small, it means trouble during the hot season and the danger of being induced to draw ice ahead to meet the Saturday demand and then have no ice for Monday, which may be a hotter day than Saturday. It would take too much time to go into every detail of ice-plant construction. I must confine myself to the management of the plant, which may be assumed to be reasonably well constructed and proportioned, and here again I must confine myself to the engine room, in accordance with the wishes of the committee in charge of the program.

You will notice that when a test has to be made of the capacity and economy of the plant, the thing that invariably happens is the surprising number of data that have to be carefully recorded. Evidently, it is needed to establish the best way of running, and it is also remarkable that the employees, knowing that these data are being taken, suddenly seem to realize that they must try to be more regular, even pay more attention to oiling, pumps, etc., feeling that if something goes wrong, the professors making the test will find it out somehow and quickly, and there will be the deuce to pay.

TUNING UP THE MACHINES FOR THE TEST

Before the tests start, the machines are "tuned up," minor repairs are made and the condensers are cleaned; in other words, the plant is put in proper condition for the test, with the expectation that this will produce better results and save the men from being accused by the party making the test of being careless or incompetent. Since a test is made to prove the best results, it must logically be the aim of the owner to produce as nearly as possible the same results all the time. Therefore, if the keeping of data tends toward better results, why not keep the same data and records all the time? I do not mean that readings should be made and entered every half-hour, as during a test, but say every two hours, or even every four hours. The mere fact that such data as condenser pressure, back pressure, water and brine temperatures must be entered at certain hours makes it necessary to pay more attention to these matters, with consequent better handling. Furthermore, it shows the night man the condition the plant was in when turned over to him.

I have found that on the average log the only things recorded are the number of cans of ice pulled and the temperature of the brine in the freezing tanks. Since it is, as a rule, rather difficult to read thermometers correctly, considering that in many cases the instrument has to be pulled out of the brine to get sufficient light, I have always advocated the installation of recording thermometers. I cannot make the point too strong that I believe it is impossible to run a compressor in the best manner without the use of thermometers; that is, without having a thermometer in both the suction and the discharge line. One might as well tell the engineer to maintain 100 lb. steam pressure, yet give him no steam gage. The object of thermometers is particularly to prevent too much liquid entering the compressor, since that liquid has circulated without doing any useful work. I cannot go into further details, but would suggest giving the engineer a table such as the following to guide him in handling the gas:

Gage Pressure, Lb.	Boiling Point, Deg. F.	Temperature at Which Suction Gas Enters Compressor, Deg. F.
12 25	—3	+3
15 67	0	+7
19 46	+5	+11
23 64	10	+16
28 24	15	+20
33 25	20	+25
38 73	25	+28
44 72	30	+33

If, for instance, the gage shows 20 lb. back pressure, then the thermometer in the suction line should show about +11

---

*From a paper before the Eastern Ice Association, Atlantic City, November, 1917.

†Consulting engineer, 90 West St., New York City.

deg. F. Then little or no liquid will go into the compressor. If the suction gas is handled rightly, the discharge gas will take care of itself. At the same time it might be well to give them also a short table as a hint how these temperatures usually run. This table is based on tests:

Back Pressure, Lb.	Single-Acting Compressor, Deg. F.	Double-Acting Compressor, Deg. F.
5	260	295
15	240	287
25	213	253

This is assuming cooling water of 60 deg. F. initial temperature. If temperature is higher, add the difference to figure given; for lower temperature deduct, etc. I have found, and quite naturally so, that the average engineer has not been told enough by the contractors furnishing the outfit, therefore even as small a table as the one given will help him.

It is also advisable to provide an indicator for the engineer and make sure that he uses it on the steam engines as well as on the compressors. Diagrams should be taken at regular intervals, say every two weeks, even if everything is apparently working all right.

I wish to call attention to the method, in many plants, of using the return gas from the freezing tanks to cool the water in the forecooler. This, in my opinion, is not economical, since it usually results in superheating the gas returning to the compressor, diminishing the capacity of the compressor by allowing less weight of gas to enter than would otherwise enter.

Keep in mind that refrigeration is based on the *weight* of ammonia evaporated—the lighter the gas returning to the compressor the more revolutions the machine has to make to handle the same weight of gas.

The use of thermometers will show at what temperature the gas returns, and any ammonia table will then show how many cubic feet of gas at that particular temperature are required to weigh a pound. If, for instance, the back pressure is 15.67 lb., the temperature of the ammonia would be 0 deg. F., and it would take 9 cu.ft. to make one pound. Now assuming that the thermometer shows 31 deg. F., or 31 deg. superheat, it would take 9.682 cu.ft. to make a pound, or about 8 per cent. loss. This also shows how important it is to have the ammonia return pipes covered. Many owners look on the pipe covering as an unnecessary expense; as a matter of fact, it is absolutely justified and pays for itself in a short time. This refers also to distilled or cooled-water lines to can fillers.

Loss of Ammonia a Source of Complaint

One of the usual complaints is the loss of ammonia, and this is always a serious matter. You can read any number of articles about the deterioration of ammonia, yet if you talk to an ammonia salesman representing a concern whose goods you are not using, he will tell you in a minute that all you have to do is to buy his ammonia and that will settle the whole question. I can truthfully say that I have never found any appreciable difference in the ammonias made by several reputable concerns. When there seem to be no leaks it is most perplexing to tell where the ammonia disappears to, and again, in other plants of similar construction, the leakage losses are really insignificant. The two places where the chances for losing the ammonia are the greatest are in the stuffing-boxes and the condensers. It is important not to allow the stuffing-boxes to leak, and to regulate the return gas so that it will have, if possible, the same temperature continuously to avoid heavy back frost, which invariably causes leaks around stuffing-boxes. If the engineer then tightens the stuffing-box to prevent this temporary leak, the chances are that later the piston rods will run hot or even cause the gland bolts to break, as I have seen happen several times.

As far as the condensers are concerned, it is natural that the danger of leaks is greater there on account of the high pressure as well as the fact that the water running over them will absorb the ammonia, so that numerous small leaks may exist for a long time without being found. When there is a perplexing loss of ammonia, I think it would be well to shut off the water over one or two condenser coils at a time, and go over them carefully. The possibility of leaks in the brine-tank coils makes it desirable to periodically examine the brine by means of Nessler's or any other suitable reagent. Peculiarly, leaks are often near the bottom of the tank and in an inaccessible place.

If the leak is not very strong, although it is a matter of fine judgment to determine that, it may be advisable to let it go until the cool season, since the operation of emptying the brine tanks, removing the ice cans, refilling, etc., is one of the worst things that can happen in an ice plant and emphasizes the importance of having only the best steel or malleable fittings and flanges and wrought-iron piping and thorough tests under pressure before the brine is put in. In many plants this is not done thoroughly enough for the simple reason that the contractor often is late with his work and does not take the proper time to test after the plant is installed. That is wrong, since it is better to finish the work a few days later than to have to interrupt the whole plant or at least one tank during the warm season for never less than a week and sometimes even more.

Leaks are started by the cans being dropped on the pipes, and sometimes on account of the brine being allowed to get weak, the cans freeze in the brine and the coils are bent by using crowbars to get the cans loose. Weak brine may freeze into the coils, forming an insulation, retarding the freezing action and cutting down the capacity. In addition, as previously stated, it may cause the more serious trouble of ammonia leaks. See to it that the brine agitators are run at the right speed. Unfortunately, the machines driving them are often of a cheap and poor make and require constant attention. Insufficient agitation means lower efficiency of tank.

One point that usually received very little attention is the water jacket of the compressors. I have inquired from several operating engineers what instructions they had received from the contractor's engineer. In no case had they received any direct instruction, and the handling of the water jacket was left to their own judgment. Generally, the water jacket should have as large and as cold a water-supply as one can manage to give it. Whatever heat is removed by the water in the jacket reduces the amount of power required to drive the compressor. I have seen the water in jackets frozen solid, caused by liquid being allowed to return to the compressor in sufficient quantity to freeze the water.

Tests of Welded Joints

A series of tests of the strength of oxyacetylene-welded joints in mild-steel plates has been completed by the Engineering Experiment Station of the University of Illinois under the direction of H. F. Moore, research professor of engineering materials. Specimens were supplied by the Oxweld Acetylene Co., of Chicago, and tests were made in the laboratories of the station at Urbana under three conditions of loading: (a) Static load in tension (in a testing machine), (b) repeated load (bending), and (c) impact in tension (in a drop testing machine).

For joints made with no subsequent treatment after welding, the joint efficiency for static tension was found to be about 100 per cent. for plates one-half inch in thickness or less, and to decrease for thicker plates. For static tension tests, the efficiency of the material in the joints welded with no subsequent treatment was found to be not greater than 75 per cent. The joints were strengthened by working the metal after welding and were weakened by annealing at 800 deg. C. (1472 deg. F.) For static tests and for repeated stress tests the joint efficiency sometimes reaches 100 per cent.; the efficiency of the material in the joint is always less. This indicates the necessity of building up the weld to a thickness greater than that of the plate. The impact tests show that oxacetylene-welded joints are decidedly weaker under shock than is the original material; for joints welded with no subsequent treatment the strength under impact seems to be about half that of the material.

In general the test results tend to increase confidence in the static strength and in the strength under repeated stress of carefully made oxyacetylene-welded joints in mild-steel plates. The results of these tests have been published as Bulletin No. 98 of the Engineering Experiment Station, copies of which may be obtained without cost by addressing C. R. Richards, Director, Urbana, Illinois.

North Jersey Severely Suffering from Coal Shortage

The industries and homes of Northern New Jersey are in the grip of a most severe coal shortage as this goes to press. The two large stations of the Public Service Electric Co., Marion and Essex, which supply much of North Jersey with electricity for industries, railways and homes, are hobbling along with but one turbo-generator running in each plant. These stations consume 1200 tons of coal per day of the pooled coal which they have been getting, but nowhere near this amount is coming in. All the company's coal reserve is used up, and though according to the Fuel Administrator's books the company still has 400 tons in the pooled coal pile, there is no pile. Some one has overdrawn his account, evidently.

The Public Service has reached the point where its officials have given up in despair. Seeing the shortage coming, it paid out a million dollars bonus to get coal; but before it reached the company's yards it was pooled or directed elsewhere. It has put the situation up to Fuel Administrator Jenkinson, who has one of his best men at work trying to keep the Public Service supplied with enough coal so that further curtailment of service will not be necessary. Many carloads of coal were on the way to the company's yards; but word came (Wednesday, Jan. 2) that these had been directed to other more urgent uses by the Government.

Wednesday, Jan. 2, the circuit-breakers were pulled and most of the industries using the company's service cut off. This came after urgent appeals to consumers to reduce consumption had failed to get results. Many of the engineering staff sat in the offices at the Terminal Building, Newark, Wednesday night and directed the load dispatcher in an effort to effect the most equitable distribution of current. The electric street lights were not turned on until 7: 30 p.m. to make available enough current to carry the trolley service over the rush-hour period.

Among the industries affected by the Public Service coal shortage are munition factories and others engaged in related work. Many of those consumers who have their own plants, but use in addition purchased current, are shut down only in those departments supplied with purchased current, though several factories are without coal for their own plants. What little coal there is at Perth Amboy, the distribution center for New York City and this section of New Jersey, is frozen into lumps, each lump filling a car.

This period of "short rations" will last at least a week, say the Public Service officials, and how much longer they do not know. Hoboken at this writing has no water, electricity, gas or coal. The locomotives in the Jersey City yards have no water and power plants are down. The great Edison plant at West Orange, the Westinghouse Lamp Works, Newark, part of the General Electric Co.'s Harrison plant, and the American Shell Co., Paterson, are closed.

The whole of North Jersey is not only hobbling along on a very greatly reduced electrical supply, but trolley service is seriously inadequate and the gas supply has been shut off from whole counties.

Heating Buildings With Sprinkler Systems

The increasing use of automatic sprinklers in modern commercial industrial buildings has led to the development of the sprinkler system for heating purposes, according to E. S. Densmore, in the *Quarterly* of the National Fire Protection Association. As is well known, the sprinkler system consists in general of a series of pipes which cover uniformly the ceilings. If the water which is maintained in the system can be heated and circulated, evidently the sprinkler piping can be used for heating. One fundamental objection is that the sprinkler head which is in ordinary use will melt at the temperature necessary for the water to be used for heating purposes. This melting of the sprinkler head is prevented by a U-connection through which the hot water cannot circulate. In practice it has been found that a bend in the horizontal nipple carrying at the end the upright sprinkler head will prevent the head from melting.

The connections of the hot-water heating system with the sprinkler piping are exceedingly simple and need not change the sprinkler piping in any way. The hot-water heater may be located in any convenient place. From the hot-water heater a hot-water supply pipe is run and connected to the foot of the sprinkler riser inside the sprinkler alarm valve. It is advisable to provide an ordinary stop valve at this point so that the hot-water supply may be entirely shut off from the sprinklers when necessary. Between the hot-water connection to the riser and the sprinkler heads no changes are made, the riser, laterals and distributing pipes being installed in the usual way. Many successful installations have been made, and apparently no fundamental difficulties have been encountered over a period of several years in operation.

Insolvency's Effect on Power Contracts

When a power company becomes insolvent and its affairs are entrusted to a receiver, who continues to operate the property for the benefit of the company's creditors, he is not bound to carry out a preëxisting contract of the company to furnish power to a particular customer. It is left to the receiver's judgment, acting under control of the court, whether he will adopt such a contract or repudiate it according to what is deemed to be for the best interests of the estate. In the absence of indication of his election to the contrary, the contract becomes automatically dissolved on the receiver's appointment. But in this case it is decided that the receiver of an electric-power company, who agreed to supply power to a manufacturer, under an independent contract entered into by him, should not be permitted to recover a fixed charge for keeping power in readiness for service whether needed or not, in the absence of proof that he had agreed to and did keep the amount of power supplied, whether used or not. (Iowa Supreme Court, Maxwell vs. Missouri Valley Ice and Cold Storage Co., 164 Northwestern Reporter, 329.)

Liability for Defective Condition

Since it is a general principle of law that one is not liable for injury sustained by another on account of a defective condition of premises, unless the defect had been previously known to the former, or had existed so long as to fairly charge him with constructive knowledge of the conditions, and ample time had elapsed in which the defect might have been repaired, the owner of a steam-power plant is not liable for injury to a pedestrian, caused by a break in a steam pipe line under a pathway used by the public where it appears that the break must have occurred between 4 o'clock in the afternoon and 11 o'clock that night, and that those in charge of the plant had no notice of the break before the accident to the pedestrian occurred. (Truschine vs. Fayette Manufacturing Co., 63 Pennsylvania Superior Court Reports, 124.)

"Coal Savers" in Great Britain

From the following it is evident that the United States is not the only territory that has been invaded by the so-called "Coal Saver." *Power* has published a number of articles dealing with compounds that are supposed to increase the heat value of coals if sprinkled upon them or when sprayed over ashes, and various preparations are extensively advertised in Great Britain at present which are presumed to contribute considerably to the heating power of coal when applied in the prescribed process.

The Director of Fuel Research, in answer to an inquiry as to the value of these preparations, states that these proprietary substances have been in the market a long time, but that there does not appear to be any genuine scientific evidence in support of the claim of their manufacturers. He concludes: "The nature of the substances makes it highly improbable that they have any effects whatever on the combustion of coal or other fuels when they are used in the quantities prescribed."

Personals

O. L. Ruley, formerly with the Union Traction Co., of Indiana, is now superintendent of the Portland Municipal plant, at Portland, Ind.

E. M. Walker, formerly manager of the Dubuque (Iowa) Electric Co., is now general manager of T. H. I. & E. Traction Co., at Terre Haute, Ind.

George W. Schmidt, formerly chief engineer of the Dubuque (Iowa) Electric Co., is now chief engineer at T. H. I. & E. Traction Co., Terre Haute, Ind.

M. H. Owens, formerly manager of Hobart City plant, Hobart, Ind., is now manager of the Inter-State Public Service Co., for Columbus and Seymour, Ind.

H. E. Smith, formerly chief engineer at T. H. I. & E. Traction Co., Terre Haute, Ind., is now chief engineer of the Indianapolis (Ind.) Light and Heat Co.'s Mill Street plant.

Charles H. Parker, who has been with the Edison Electric Illuminating Co., of Boston, for the last 22 years, has been appointed superintendent of the generating department, of which he has been assistant superintendent for 17 years.

Milton Kraemer, consulting engineer, of San Francisco, has undertaken an investigation into the utilization of coals, mined in California and neighboring states, for use as fuel in a pulverized form. This will be a continuation of a study made in 1916 and the early part of 1917, for some of the large California power companies.

Frank W. Hall has been appointed commercial manager of the Sprague Electric Works of General Electric Co. With the exception of a short period, Mr. Hall has been connected with the Sprague Works continuously for 22 years in various engineering and sales capacities, and for the three years prior to his present appointment occupied the position of sales manager. He succeeds D. C. Durland, former executive head of the Sprague Electric Works, who resigned to acecpt the presidency of the Mitchell Motors Company, Inc.

Business Items

Gannestad & Jacobsen, engineers, of Pittsburgh, Penn., have removed from the Benedum-Trees Building to Suite 1103-1106, B. F. Jones Building, where they have more spacious quarters to take care of increasing business.

Engineering Affairs

Fuel Conservation in Boiler Rooms is the subject of a meeting under the auspices of the Baltimore Section, American Society of Mechanical Engineers, the Engineers' Club of Baltimore and the City Club at the rooms of the last, Thursday evening, Jan. 10. Efforts are being made to have a large attendance of firemen, among others. Charles H. Bromley, associate editor of "Power," will give the main address of the evening, followed by W. L. DeBaufre, of the United States Naval Experiment Station, Annapolis, Md., and others. The meeting will be the first of a number to arouse more general interest in fuel economy in boiler plants.

Miscellaneous News

Public Hearing on New Jersey Boiler Code—Before the code formulated by the State Board of Boiler Rules is adopted finally, a public hearing will be held at which minor changes will be discussed. This was the decision of the board at a conference recently held, presided over by J. F. Scott, chief of the License Board of the Bureau of Engineers.

According to the November Bulletin of the New York State Department of Labor, the metals, machinery and conveyances group had an addition of more than 1 per cent. to the number of employees, and paid 3 per cent. more wages in November than in October. The water, light and power group in November had more than 1 per cent. additional employees, and a slightly greater payroll than in October. As compared with the corresponding month of last year, November reported gains of 4 per cent. in the number of employees and 19 per cent. in the wage volume.

New Power Site Reserve—The Secretary of the Interior recently recommended, and the President has approved, the inclusion within a power-site reserve of about 196 acres of public land in the Big Sandy River Basin, Oregon, in order that this land may be used in connection with the development of power, but not for other purposes. Big Sandy River has its source on the western slope of the Cascade Range, and its principal tributaries are fed by the glaciers of Mount Hood. The land recommended for withdrawal is located near or adjacent to Big Sandy River below the mouth of Salmon River.

The withdrawal for power-site purposes of a tract within the Eldorado National Forest, Cal., has also been recommended by the Secretary of the Interior and approved by the President.

Free Class for Radio Operators at Stevens Tech.—A free evening class to train men as radio operators for the Signal Corps will soon be started by the Stevens Institute of Technology at Hoboken. Those who actually expect to be called to the colors will be admitted into the class if prompt application is made to Prof. L. A. Hazeltine, head of the Department of Electrical Engineering, under whose supervision the course will be conducted. The definite object of the course which will require four evenings each week, is to develop radio or buzzer operators so as to be able to send a minimum of 20 words per minute. Upon finishing the course, which requires about 200 hours, less for some and more for others, a certificate of attainment will be given. The course is offered specifically for those who desire to enter a cantonment trained and ready to do a specific job. The authorities at Washington state "that drafted men who attain the required proficiency are practically certain of rapid promotion and increased pay in the Army. The rank of corporal and sergeant with a wage of from $36 to $51 a month awaits the majority of men thus trained, and in proportion as a man so instructed shows his ability and interest, promotion lies ahead of him to the position of Master Signal Electrician, with a wage of $81 a month.

The Army and Navy Staff Departments continue to demand men of engineering experience, especially in industrial lines. At present the outlook is that this demand will continue throughout the period of the war. In calling attention to this, the United States Public Service Reserve, Washington, D. C. (where records of men willing to serve when called will be kept on file), points out that a man of engineering experience has a rare combination of opportunities open to him, which are not open to the average patriotic American, as follows: (1) To serve the country in his most effective capacity; (2) to keep in touch with his own profession, with the result that his patriotic service will not have caused him to become rusty by the time peace returns; (3) to become a commissioned officer and receive much better pay than the average man who has wholly subordinated personal interests and now works for the national good; (4) to perform his service usually without leaving the United States

Technical Troops for France—Skilled engineers and "handy men" wanted, 18 to 21 or 31 to 40. Jerseymen, volunteer before these regiments are filled from other states. There are now being organized and enlistments are invited for (N. A.): 20th Engineers (Forestry), 23rd Engineers (Highway), 24th Engineers (Shop and Supply), 25th Engineers (Construction), 26th Engineers (Water Supply), 27th Engineers (Mining), 28th Engineers (Quarry), 30th Engineers (Gas and Flame), 37th Engineers, 38th Engineers (Crane Operators), Engineers Unassigned, Washington, D. C. All applicants are enlisted as privates; but may soon advance as corporals and sergeants when found qualified. Applicants must have the same physical examination as any other recruits. A technical worker or handy man in any of the mechanical industries will find in the above field of enlistment a rare opportunity. If of draft age no man can volunteer. Enlistment is for the period of the war only. No cards from Engineer Officers are required except for 37th and 38th Engineers (N. A.) The enlisted personnel of the Engineers N. A. (Crane Operators) will be approximately as follows: 200 locomotive crane operators (operation of railway constructing derricks, cargo-handling machinery on lake, ore and coal docks and first-class steam shovel runners), 32 Rotary Tenders, 16 Armature Winders, 16 Electrical Foremen, 16 Storage Battery Charging Men, 16 High Tension Wiremen, 144 Journeymen Electricians, 8 Cooks. It is proposed to limit enlistments in the 37th and 38th Engineers N. A., to those men whose vocational training has been examined and approved by officers representing the Engineer Department. Applications for enlistment in the 37th Engineers should be addressed to Chief of Engineers, Washington, D. C., and in the 38th Engineers to same or to the Director General of Railways, Washington, D. C. For the other Engineer Regiments (N. A.) apply direct to any recruiting office. The above regiments are National Army. In addition, men are accepted for the Engineers, regular army. Recruiting stations: Main office, 86 Park Place, Newark, N. J., near McAdoo Terminal; Paterson, 269 Main St.; Passaic, 215 Main Ave.; Elizabeth, 55 Broad St.; Trenton, 103 E. State St.; New Brunswick, Post Office Bldg.; Atlantic City, 1536 Atlantic Ave.; Perth Amboy, 130 Smith St.; Camden, 540 Federal St.

Volunteers Wanted in Ordnance Corps—For every man on the firing line there are skilled men back of the line upon whose help and coöperation he depends. The enlisted Ordnance Corps of the National Army, into which the Ordnance Enlisted Reserve Corps has been merged, is that army behind the army which the great war has made more important than ever before. Unless the fighting man in the front-line trenches has the help and skilled coöperation of specialists behind him, his work is seriously hampered This is a war of specialists, and a man can serve his country efficiently by applying the result of his civilian experience to the work of the army. In the Enlisted Ordnance Corps, the skilled man continues the same type of work he pursues in civil life. The acceptance or card from an ordnance officer is no longer needed. The chief of ordnance is charged with the supply, maintenance, and repair of all cannon and artillery vehicles and equipment; all machines for the service and maneuver of artillery; all small arms, ammunition, harness, motor trucks, motor cycles, railroad cars, and also every device for the mechanical service of the front-line army. There is a definite place in the ordnance corps for the skilled man in almost every line of trade: Machinists, mechanics, plumbers, painters, tinsmiths, carpenters, auto mechanics, saddlers, blacksmiths, and wheelwrights are especially needed at this time. Military training, while desirable, is not essential, as men will continue the type of work they pursue in civil life, thus saving the Government a long period of instruction, and also greatly improving their own chances for advancement. If you are a skilled artisan, join the army behind the army. If handy with tools, perfect yourself with these technical troops. If accepted for enlistment, men will ordinarily be sent to an arsenal for a short period of instruction, upon completion of which they will be assigned to detachments, units, or organizations, with ultimate service abroad. Applicants must be between 18 and 21 or 31 and 40 years, and must be able to pass a physical examination conforming to that prescribed for the regular army. Registrants are not eligible for voluntary enlistment. In view of the work of the Enlisted Ordnance Corps, National Army, and the fact that the men in the first-line trenches depend upon their help and coöperation, a large number of men will be promoted as noncommissioned officers. Pay ranges from $30 to $61.20 a month, depending upon demonstrated ability and place of service. Enlistment is for the duration of the war only. In addition to the regular pay, free quarters, rations, clothing, bedding, medical and dental attention are provided by the Government, and 20% increase while on foreign service. There are also vacancies in other branches of technical troops: Aviation; Quartermaster Corps; Engineers; Sanitation, Hospital Corps; Heavy Artillery, Field Artillery. Also in the line: Infantry, Cavalry, U. S. Guard, etc.

How to enlist: If you are a mechanic or have a trade, call either at the Main Army Recruiting Station for New Jersey, at 86 Park Place, Newark, N. J. (near the McAdoo Tube Terminal), or at any of the following branches: 540 Federal St., Camden; 130 Smith St., Perth Amboy; 103 E. State St., Trenton; 55 Broad St., Elizabeth; 269 Main St., Paterson; 215 Main Ave., Passaic; Post Office Bldg., New Brunswick; 1536 Atlantic Ave., Atlantic City.

If working during the day, call until 9 P.M. for information.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Jan. 3, 1918	One Year Ago	Jan. 3, 1918	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

PROPOSED CONSTRUCTION

Ala., Mobile—The Mobile Electric Co. plans to build a 5-mi. transmission line to the Chickasaw Shipbuilding plant now under constructon. T. K. Jackson, Mgr.

Ark., Stuttgart—S. R. Morgan & Co., Little Rock, has been granted a franchise to build and operate an electric-lighting and power plant. Estimated cost, $100,000.

Calif., Palo Alto—The City Council plans an election soon to vote on $6600 bonds for the installation of a Diesel engine and an electric generator for the power plant.

Colo., Salida—The Colorado Power Co. plans to double the capacity of its local steam plant in order to supply the Rawley mine with electricity. W. E. Robertson, Mgr.

Ga., Atlanta—City plans to install an electric generating plant at the city incinerating station. A. Turner, City Electrician.

Idaho, Shelley—City plans to install an electric-lighting system.

Ill., Joliet—The Chicago & Joliet Electric Ry. Co. plans to build 2 substations, 1 at Osgood and St. Louis Sts. and the other at Delwood Park. Estimated cost, $50,000. J. R. Blackhall, Gen. Mgr.

Iowa, Marshalltown—The City Council plans to build a new electric-lighting plant and install new machinery and equipment. W. H. Steiner, Engr.

Kan., Burns—City plans to install an electric-lighting plant. Estimated cost, $10,000. C. A. Beebe, City Clk.

Md., Mt. Savage—The United Big Vein Coal Co. plans to install electrical mining machinery and completely electrify its plant.

N. J., Hightstown—Grover Bros., Broad St., plans to install an electric-lighting plant in connection with its works.

N. Y., New York—(Borough of Brooklyn)—The Transit Development Co., subsidiary of the Brooklyn Rapid Transit Co., has had plans prepared for the erection of an addition to its generating power station on Kent and Division Ave. Estimated cost, $500,000. H. A. Robbins, 85 Clinton St., Supt. of Power.

Ohio, Cleveland—City is having plans prepared by F. H. Betz, Arch., City Hall, for the erection of a 4-story, 80 x 250-ft. addition to its electric-lighting plant on 53rd St. Estimated cost, $1,750,000. Noted Sept. 25.

Ohio, Cleveland—The New York Central R.R. plans to build a 40 x 79-ft. power house and install new electrical equipment, generators, motors, etc., here. J. W. Kittredge, New York City, Ch. Engr.

Okla., Durant—The Consumers' Light and Power Co. plans to rebuild and equip its electric-lighting plant which was damaged by fire. W. H. Williams, Engr.

Okla., Miami—The Bilharz Mining Co. plans to build a central electric generating plant to supply power for plants 1, 2 and 3.

Ont., Perth—The Hydro-Electric Commission plans to build a 26,400-volt transmission line between Perth and Smith's Falls.

Ont., Wiarton—The Hydro-Electric Power Co., Ontario, is having plans prepared for an electric-light and power plant to be erected here.

Ont., Windsor—The City Commissioners plan to install 2 new electrically driven pumps in its pumping plant.

Penn., Coaldale—The Panther Creek Valley Hospital is having plans prepared by L. Stockton, Arch., 35 West 39th St., New York City, for the erection of a 1-story power house. Estimated cost, $8000.

Que., Valleyfield—The Montreal Cotton Co. plans to rebuild its power plant which was recently destroyed by fire. Loss, $100,000.

S. D., Preshn—O. E. Helgerson has been granted a franchise for the installation of an electric-lighting system.

Tex., Marfa—The Marfa Electric and Ice Co. plans to install additional machinery in its electric-lighting and power plant.

Wash., Glacier—The Lone Jack Mining Co. plans to install a power plant at its works on Silesia Creek. Estimated cost, $20,000.

Wash., Seattle—The Puget Sound Machinery Depot is having plans prepared for the erection of a 160 x 240-ft. boiler shop and will install new machinery and equipment in same.

W. Va., Ansted—The Mill Creek Colliery Co. plans to rebuild its power plant which was recently destroyed by fire. Loss, $40,000.

Wis., Kaukauna—The Kaukauna Electric Light Co. plans to extend its transmission line to Fairview Heights. W. B. Montgomery, Mgr.

POWER

Vol. 47 NEW YORK, JANUARY 15, 1918 No. 3

THE BOYS WHO SWING the SHOVELS DOWN BELOW

BY W. A. DUNKLEY

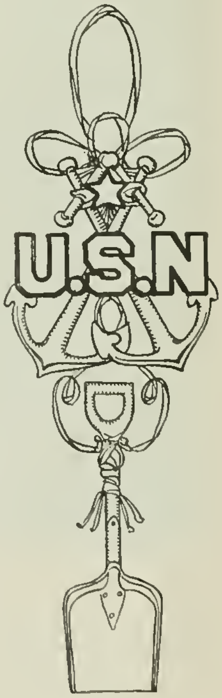
IN THESE DAYS of high excitement, when all eyes are on our fleet,
And much homage on our sailors we bestow,
Let us not forget to honor and to give due share of praise
To the boys who swing the shovels down below.

THEIR DEEDS may lack the glitter of the men above the deck,
As they toil and sweat deep down within the hold,
But their courage is as noble and their service is as great,
Though the valor which they show is seldom told.

THEY DO NOT SHOOT torpedoes and they do not work the guns,
But they fit as much into the general scheme,
For you cannot fight a battle and you cannot chase the foe
Unless you have a good supply of steam.

WHILE, ABOVE, the battle rages, you will find them on the job,
Sweating blood and grimly hanging to their task;
And if the good ship founders, then their hope of life is small,
But the chance to serve their country's all they ask.

SO IN VICTORY or disaster give these boys their honor due,
Count them heroes in a land where heroes grow;
And remember that our Navy has no braver names enrolled
Than the boys who swing the shovels down below.



Multi-Stage Compression Plant of Central Cold Storage Co.

Modern two-unit ammonia plant of 500 tons refrigerating capacity employs new D. I. Davis system of multi-stage compression with cooling of vapor between stages. It is expected to save in power 25 per cent. over the standard simple compressor and to develop one ton of refrigeration on less than 25 lb. of steam per hour.

FOR low-temperature work where brine temperatures running below zero are required, the standard compression plant has not been looked upon with favor. Boosters have been employed to increase the capacity of the compressor, but more often this class of work has been regarded as belonging to the absorption plant. The poor economy of the compression system in this work is due to several factors, developing as a direct result of the low suction pressures corresponding to the low temperatures in the refrigerator. As the suction pressure is reduced, there is a rapid falling off in the capacity of the compressor without a corresponding reduction in the power required. At lower suction pressures the ammonia vapor occupies more space and the volumetric efficiency is reduced. For example, with a suction pressure of zero, one pound of ammonia would occupy about 17.6 cu.ft.; with a 30-lb. suction pressure, only 4.5 cu.ft. For these reasons the standard single-cylinder compressor was both uneconomical and expensive for low temperatures.

In the development of the compression system[1] devised by D. I. Davis, of Chicago, and perfected commercially by the Vilter Manufacturing Co., the above objections have been eliminated and extremely low temperatures can be economically produced. The outstanding features of the new system are multi-stage compressors and the cooling of the vapor between stages by the refrigerant to a temperature corresponding to the saturation point for the intermediate pressure. The use of two cylinders decreases the temperature range per cylinder with the attending advantages, and reduces the heat of compression. The cooling between stages permits of making the high-pressure cylinder smaller and keeps down the temperature of the discharge to the condenser.

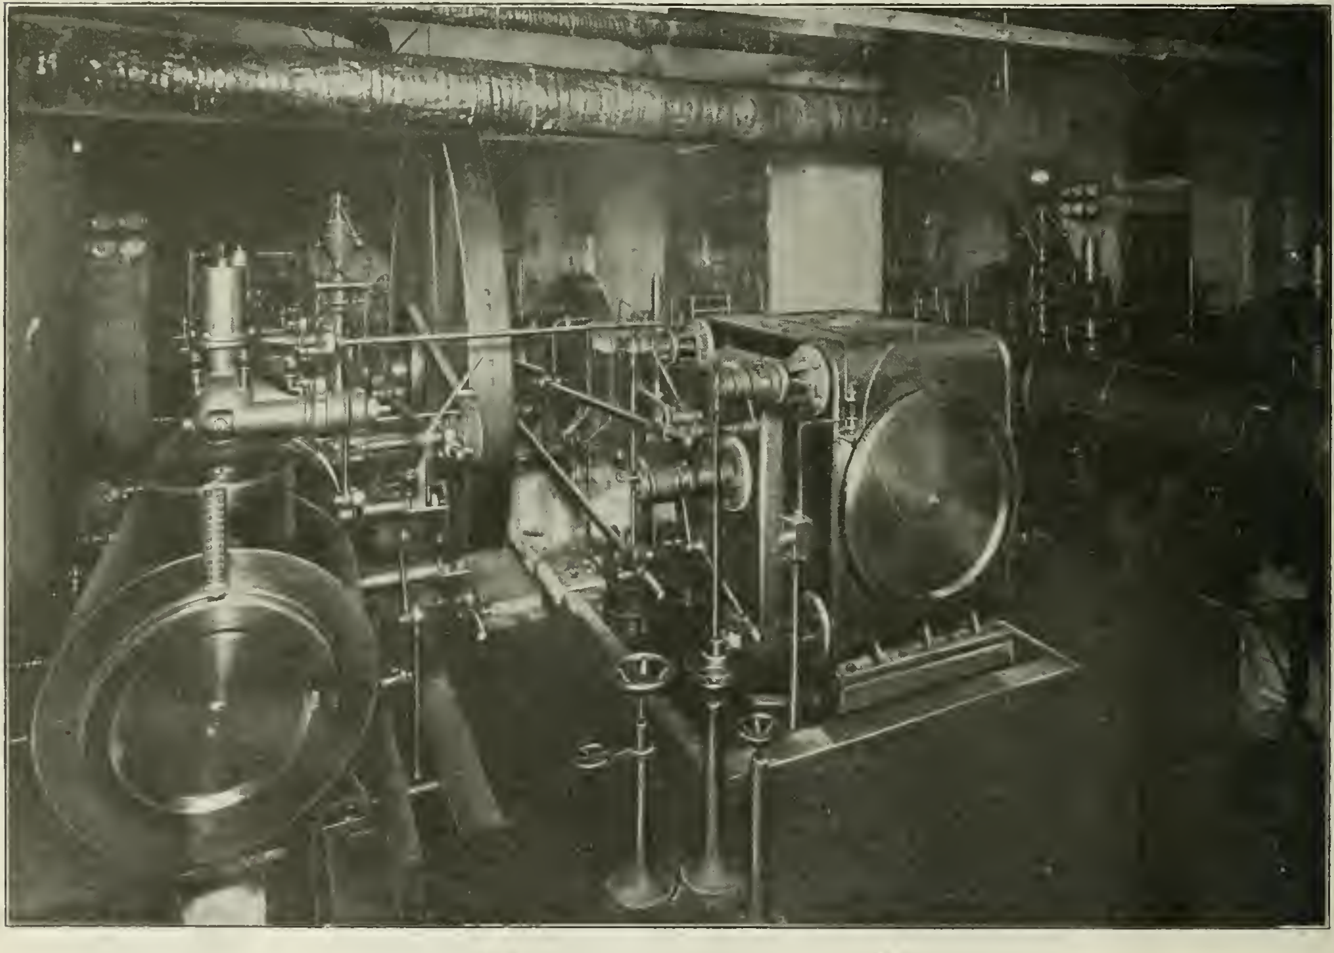


FIG. 1. STEAM END OF ONE OF THE 250-TON COMPRESSORS

A two-unit 500-ton plant of this type has been installed recently by the Central Cold Storage Co., Dearborn and Kinzie Sts., Chicago. The building is a 14-story structure of steel and reinforced concrete faced with brick. It is adjacent to the Chicago & North

---

[1] See "Power," Dec. 19, 1916, p. 844.

Western R.R. tracks, has excellent facilities for teaming and is a short distance from the Chicago River, from which feed water for the boilers and condenser cooling water is obtained. The building contains over 9 acres of floor area and 3,500,000 cu.ft. of cold storage.

The first floor is given over to receiving and shipping. Cooling rooms in which the temperature ranges from 30 to 40 deg., depending upon the product stored, occupy the second to the eighth floors inclusive, and from the ninth to the fourteenth floors are freezers with temperatures of 10 deg. below zero maintained by brine circulated at temperatures ranging from 18 to 22 deg. below zero.

The building has a total of 39 refrigerated rooms. It is divided into six independent sections and is equipped with 60 miles of 2-in. piping for circulating the brine. In each room the coils are divided into sections, and only as many sections as are needed to give the desired temperature are used. Temperature regulation is effected in this way rather than by varying the temperature or circulation of the brine.

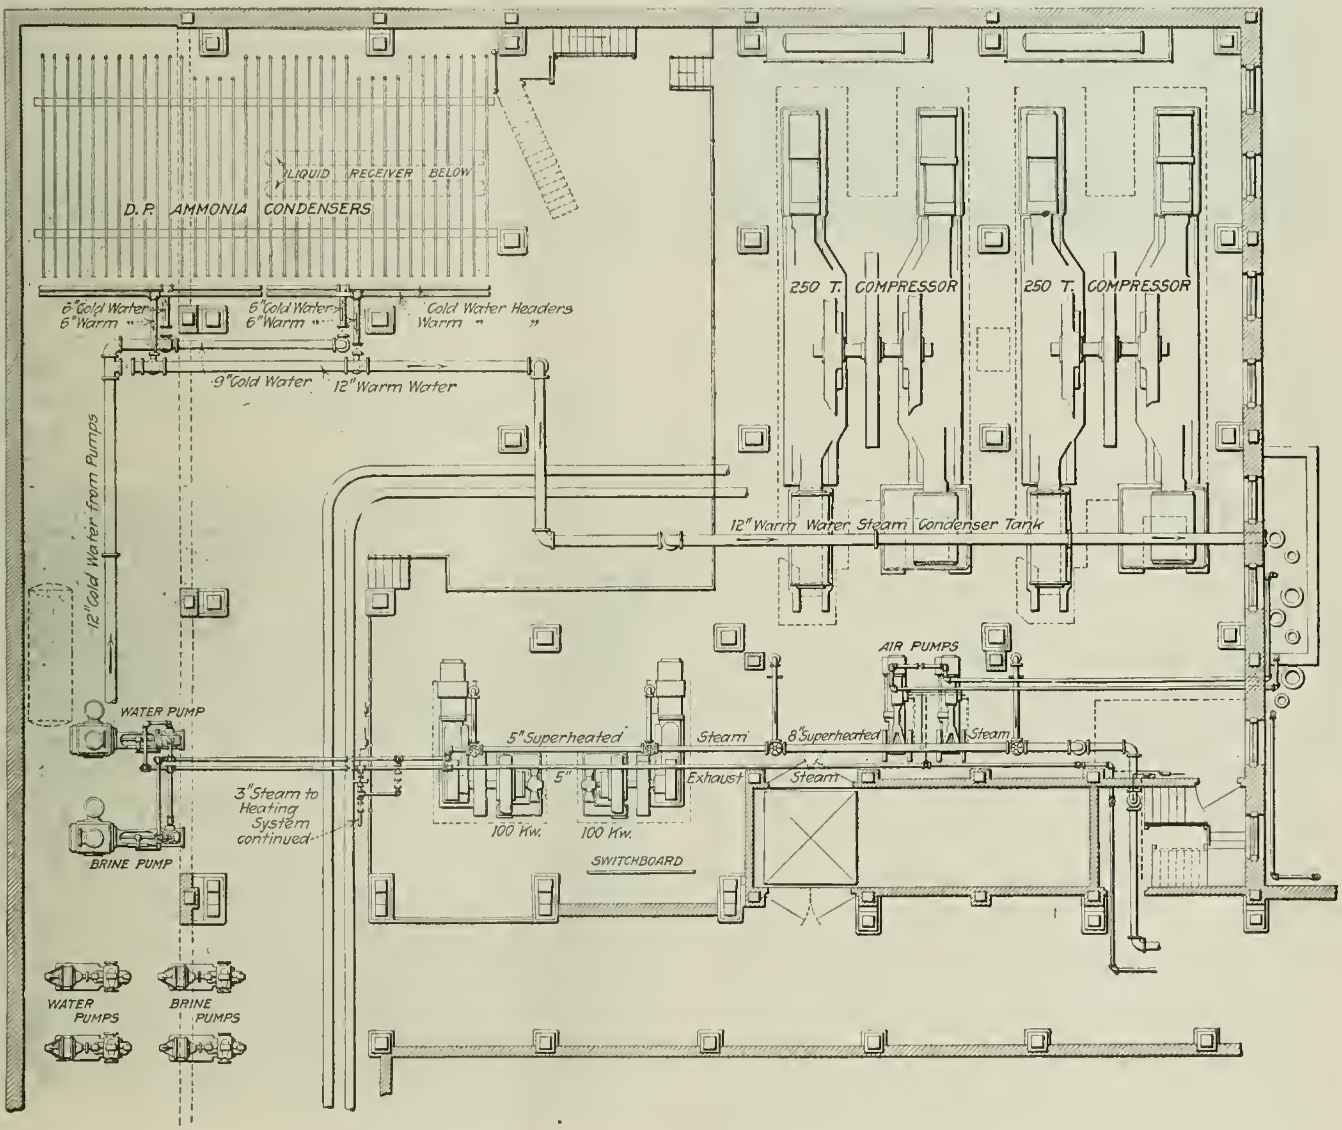

FIG. 2. LAYOUT OF EQUIPMENT, CENTRAL COLD STORAGE CO., CHICAGO, ILL.

To insulate the building required more than 1,500,000 board feet of corkboard. The insulation runs continuously from the second floor to the top of the roof slab. The first layer of cork was bonded to the brick surfaces of the walls by a ½-in. bed of portland-cement mortar. The second layer of cork was then erected against the first in a bed of hot asphalt and held in place by hickory dowel pins. All joints of the second course were broken, with respect to those of the first, and sealed with hot asphalt. All exposed surfaces throughout the building were finished with two coats of portland-cement plaster to a thickness of ⅝ inch.

All exposed wall areas from the second to the ninth stories were insulated with 5 in. of cork and wall surfaces abutting adjoining buildings with 4 in. of cork. From the ninth story to the roof where the freezers are located, 6 in. of cork, composed of two layers of 3 in. each, is used. Two partitions running from the second floor to the roof and dividing the building into three distinct sections, also have 6 in. of cork. The entire second floor was insulated with 4 in. of cork in two layers, and the third-floor ceiling over the offices and display rooms has 5 in. of cork insulation laid in concrete forms and suspended from the under-ceiling slab. The ninth floor is insulated also with 5 in. of cork in 3-in. and 2-in. layers laid in concrete forms, bound together with ½ in. of portland cement and adhered to the concrete slab when it was originally poured. The roof area was insulated with two layers of corkboard, one 4-in. and one 3-in., laid in hot asphalt and covered with seven-ply built-up roofing. The building columns from the footings in the sub-basement to the third-floor slabs are covered with two 2-in. layers of cork. Forms were then placed around the insulated steel columns and a layer of concrete poured over the cork.

In the sub-basement of the building is the refrigerating plant, the general layout, with the exception of the boiler room, being shown in Fig. 2. The compressors are of the double-acting cross-compound type. The low-pressure cylinder, or the first stage of the compressor, is 28-in. diameter by 48-in. stroke, while the diameter of the high-pressure cylinder is 20½ in. The compressor is directly connected to a cross-compound condensing engine, 20 and 42 by 48 in., the high-pressure cylinder being of the poppet-valve type designed for superheated steam and the low-pressure cylinder equipped with standard Corliss valve gear. The speed is 60 r.p.m. The flywheel is 18 ft. diameter and weighs approximately 28,000 lb., as compared to 300,000 lb. for the entire unit. The floor space occupied by each unit is approximately 18 × 46 = 828 sq.ft., or 3.3 sq.ft. per ton of refrigerating capacity.

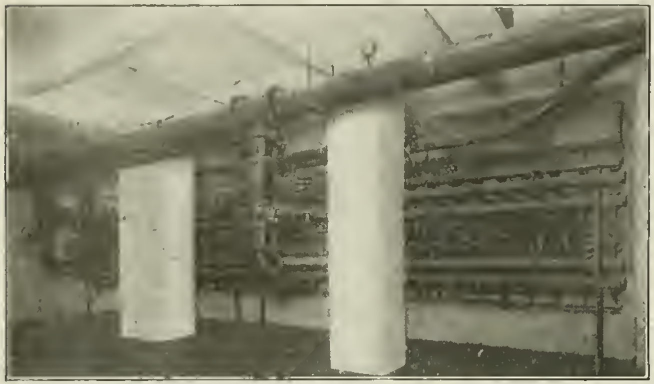

FIG. 3. DOUBLE-PIPE CONDENSERS

Both compressors and engines are equipped with a central oiling system with telescopic oilers on crank and crosshead pins and sight feeds on other bearings. The oil is supplied by gravity from an overhead tank. The surplus from the bearings is drained to a tank below the floor level and pumped back through a filter to the overhead tank. There are also force-feed pumps for cylinder lubrication and sight-feed oilers for the exhaust-valve levers of the high-pressure steam cylinders.

The steam end of each unit is supplied with a barometric condenser, giving about 27½ in. of vacuum, and the compressor end has a double-pipe ammonia condenser. The latter has 12 sections 12 pipes high, made up of 2- and 1¼-in. pipes 20 ft. 6½ in. long. The condenser is divided to give satisfactory distribution of the water, which is drawn from the river by any one of three circulating pumps. Two are centrifugal pumps, one for each unit, each having a capacity of 1000 gal. per min. and driven by a 40-hp. motor, while the third is a direct-acting 16 and 20 by 20-in. simplex steam pump. Under normal conditions, each condenser requires about 635 gal. of water per minute. After the water has passed through the ammonia condensers, part of it passes to a large tank between the second and third floors for boiler feeding and the balance through the barometric condensers back to the river.

Calcium-chloride brine of density 1.260 is used. Its temperature is lowered to 22 deg. F. below zero in four brine coolers of the horizontal shell type, two being provided for each compressor. Each cooler has twelve sections and a capacity to care for 150 tons of refrigeration. The brine is circulated through the house and discharged into an open tank on the top floor, returning thence to the pumps and again passing through the same cycle. The system is thus practically balanced, with only a 20-lb. friction head to overcome. In type, capacity and number, the brine pumps are the same as those used to circulate the condenser water, with the exception that the centrifugals are driven by 30-hp. motors.

Steam is supplied to the plant by two 400-hp. Stirling boilers generating steam at 175 lb. pressure and 103 deg. superheat. The boilers are served by chain grates and natural draft is supplied by a steel stack 6 ft. 4 in. diameter and 195 ft. 4 in. high above the boiler-room floor. Coal comes in on the railway tracks serving the building and is dumped directly into the coal bunker underneath and is wheeled to the boilers. From pits under the stokers the ashes are shoveled into the boot of a bucket elevator discharging into a concrete tank on the second floor, with a chute leading to the railway cars.

As previously stated, feed water comes originally from the river, first passing through the ammonia condenser, then to a large storage tank and finally under float control to an 800-hp. open heater. Duplicate simplex feed pumps, 10 and 6 by 12 in. take the water from the heater and feed it to the boilers. At each boiler is a manifold, from which the feed may be supplied to the boiler through a ¾-, 1- or 1¼-in. valve, the choice of valve depending upon the rate at which the boiler is being driven. In this way the demand for water can be followed closely and the pump maintained in constant operation, with little need for regulation.

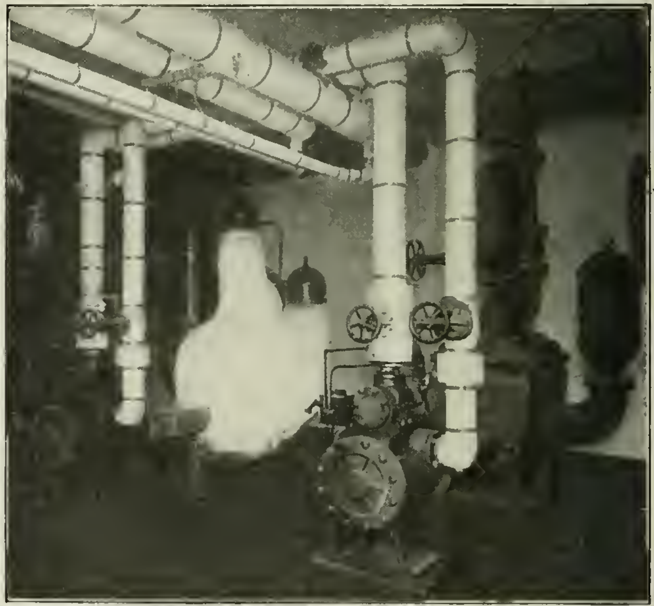

FIG. 4. BRINE AND WATER CIRCULATING PUMPS

To supply electric light and power to the six electric elevators serving the building and to the motors driving the pumps, fans and ash hoist, two 100-kw. direct-current generating units have been installed. The ammonia-compressor engines are of the uniflow type, 15 x 17 in. At the time of the writer's visit, one of the barometric condensers was serving a compressor engine and the two lighting units. The vacuum approximated 27½ in. The generators are directly connected and are rated to deliver 400 amp. at 240 volts. The load runs as high as 700 amp., so that the two units are frequently required.

Having reviewed the equipment of the plant, the ammonia cycle may be followed more clearly. Ammonia vapor from the brine coolers is drawn to the low-pressure cylinder of the compressor at a pressure of 1 to 4 lb. From the low-pressure cylinder it is passed to an intermediate drum having a pressure of 25 to 30 lb. The vapor heated by this compression is cooled by wet vapor coming from a liquid cooler located between the condensers and the brine coolers. There is also means of introducing liquid ammonia into this drum if required and a trap to return excess liquid to the liquid cooler. The vapor cooled to the temperature corresponding to the saturated point at this pressure then passes to the high-pressure cylinder and is further compressed to a condenser pressure of 165 lb. It is necessary to cool the liquid ammonia coming from the condenser to a temperature corresponding to its evaporation point before it can do useful work. Instead of doing all this in the refrigerator, or in this case the brine coolers, the liquid is passed through the liquid ammonia cooler, previously referred to, located between the condensers and the brine coolers. Ammonia from the liquid receiver at the condenser is expanded into the cooler and is returned to the high-pressure cylinder through the intermediate drum as previously explained. Coming from the condenser the liquid ammonia has a temperature of 90 deg. F., and when leaving the heat exchanger or liquid cooler, its temperature is reduced to 17.5 deg. F. This drop in temperature of 72.5 deg. is effected with a suction pressure of 25 to 30 lb. instead of the 1 to 4 lb. for the low-pressure cylinder. In the brine coolers the liquid must be cooled to its evaporating temperature, a comparatively small range. It is apparent that considerably less vapor than in the usual compression system must be handled by the low-pressure cylinder. It can therefore be made smaller and the power required per ton of refrigeration will be less.

Unfortunately, no complete test data are as yet avail-

able. For three months previous to the present writing the plant had been in operation, carrying at least 3,000,000 cu.ft. of storage space. This load has never required more than one machine, and the usual practice is to run this one machine about 16 hours out of the 24. If the compressor is developing its rated capacity, 12,000 cu.ft. of space is being refrigerated per ton of refrigeration, with the compressor running two-thirds of the time and approximately one-half the space for low-temperature work, 10 deg. below zero in the freezers and brine at —18 to —22 deg. F. The temperature of the returning brine ranges from —12 to —16 deg. F., giving a rise of 6 deg. F. through the house. The average daily coal consumption for lighting, power and refrigeration has been as follows: July, 12.2 tons; August, 12 tons; September, 10 tons. On a basis of 11.4 tons per day, the average for the three months, 950 lb. of coal would be burned per hour. Of this it is estimated that 240 lb. is required by the generating units, leaving 710 lb. of coal per hour for the compressors, air pumps serving the condensers and the brine and water circulating steam pumps. This reduces to 2.84 lb. of coal per hour per ton of refrigeration, or with an evaporation of 8 lb. of water per pound of coal, 22.7 lb. of steam. From previous test data it is expected that the steam requirement per hour per ton of refrigeration will be held close to 20 pounds.

While the figures given are only approximate, it is evident that exceptional efficiency is being obtained not only from the refrigerating plant, but from the insulation as well. Test data, to be available soon, will be received with interest.

D. I. Davis and Co., architects and engineers, designed the plant and the refrigerating equipment was installed by the Vilter Manufacturing Co. L. E. Gibbons is chief engineer in charge of operation.

Suspended Templets and Their Application[*]

By TERRELL CROFT

Something about suspended templets for use where large foundations are to be constructed. Their advantages are pointed out, and various methods of suspending them are shown.

A SUSPENDED templet may be defined as one that is supported over and at a considerable distance above the foundation for which it is to locate the anchor-bolt positions. Fig. 1 gives a graphic definition, wherein *A* is the suspended templet hung from the roof-truss chords over the foundation excavation immediately below it. The applications for which suspended templets are desirable are those where a very large foundation or one that will contain a considerable number of anchor bolts is to be constructed. A templet of this character may, where the excavating is to be done by, and the foundation material to be handled with cranes, insure more economical construction. The reason is that the templet is supported in such a position that the movement of the material will not displace it or displace the foundation-bolt locations which it determines. Furthermore, it cannot be displaced by careless workmen or by material dumped from the cranes. The disadvantage of the suspended templet is that it is more expensive to erect than is one which is supported directly over and by the forms for the foundation.

The method of locating anchor-bolt positions with a suspended templet may be understood by a consideration of Fig. 1. The templet, *A*, has a small hole bored through it over each of the anchor-bolt locations. When it is desired to locate an anchor-bolt position in the foundation under construction, a plumb-bob is fastened successively to each of the cords *D*, which are dropped through the hole in the templet above; thus the pocket *B*, which is to be provided under each anchor bolt, is located. The form for the pocket is constructed in its proper location on the foundation footing, and the anchor plate, if it is to be built into the foundation, is placed in position. The forms for the pockets may be of either brick or wood. Each anchor plate is centered on the top of the pocket under the plumb-bob *E* suspended from above.

The forms are then constructed and the anchor-bolt casings *C* are placed to provide holes through the foundation for the anchor bolts. The anchor bolts are not inserted until after the foundation has been completed and the machinery which is to be mounted on it has been set in position. The anchor-bolt casings are supported at their bottoms by the anchor plates or by the upper faces of the pocket forms. At its top each anchor-bolt casing is braced to the top of the foundation form. The location of the top of each casing is, after it has been erected, checked again by plumbing down from the templet above. When the drop-lines from the templets are not in use, they are tied up high enough to be out of the way. When the crane is to be used, all the drop-lines must, of course, be pulled clear up above the templet so that they will not interfere with the movement of the crane. The plumb-bobs on the drop-lines are used only for transferring the points down from the templet to the foundation while the forms are being erected and to check the accuracy of the locations as the installation progresses.

In constructing templets for suspension, practically the same methods are followed as are used in assembling the templet for any large foundation. Ordinarily, the templet is made of planed $\frac{7}{8}$-in. planks fastened together with screws. It is first laid out and assembled either completely or in sections in the carpenter shop. Then it is carried to the building where it is to be suspended and either put together on the floor to form a complete unit and raised to its position under the roof trusses, or it may be raised in sections and then assembled on the timbers provided for its support just under the roof-truss bottom chords.

In locating the templet in its position under the roof-truss chord, the principal center lines are, by means of a transit, transferred from some reference point, either on a roof truss, side wall or column, to

DETAIL OF WASHER WEIGHT AND PLUMB BOB HOOK CONNECTION

FIGS. 1 TO 8. APPLICATION OF SUSPENDED TEMPLETS the templet itself, which must then be shifted on the timbers which hold it on the trusses until the templet has been accurately located in its position. A transit should be used, as just described, to center the templet both longitudinally and transversely. At the same time the principal center lines should be marked on some permanent member, such as a roof truss or wall, near the suspended templet so that the position of the suspended templet can, in the future, be checked for accuracy if necessary.

How templets are supported from the roof trusses is shown in Figs. 2, 3, 4 and 5. The planks upon which the templet rests (Fig. 3) are called templet-supporting-timbers. These have been shown shaded in the diagram of Fig. 2 so that they may readily be distinguished from the templet itself. These timbers are hung from the roof truss chords (Figs. 3, 4 and 5) and are braced in all directions so that they cannot shift after the templet has once been located in position and pinned to them with nails. For hangers, either portions of planks, bolts or iron rods threaded on both ends may be used.

Wooden hangers for templet-supporting timbers are assembled so that they form a yoke or tie over the roof-truss lower chords, as shown in Fig. 4. The assembly of Fig. 3 shows a templet-supporting timber sustained from each of two truss chords with wooden hangers. The braces provided to prevent longitudinal movement are also indicated in this illustration.

Hanger Bolts for Supporting Timbers

Bolt hangers for templet-supporting timbers may be employed as detailed in Fig. 5. The bolts thus used are available for other services after the foundation has been completed; $\frac{5}{8}$-in. rods threaded and provided with nuts on both ends constitute good tension rods for this service. Where hanger bolts are employed, two sticks with wooden separators between them are used to make up each girder. The bolt then passes through the space between the two timbers. A thorough system of bracing must be used to prevent any possibility of the shifting of the templet-supporting timbers. In Fig. 5 the position which the templet would occupy has been shown by dotted lines.

The best material for the drop-lines is a medium-weight linen fishline. Brown manila twine is probably next best. Ordinary white cotton twine is not satisfactory because it is not sufficiently strong.

The method of attaching the drop-lines to the templet is detailed in Fig. 6. *F* is a hole $\frac{3}{32}$ or $\frac{1}{8}$ in. diameter through which the drop- or plumb-line is passed to the foundation below. Into the templet near each hole a nail *G* is driven, to which the upper end of the plumb-line can be tied.

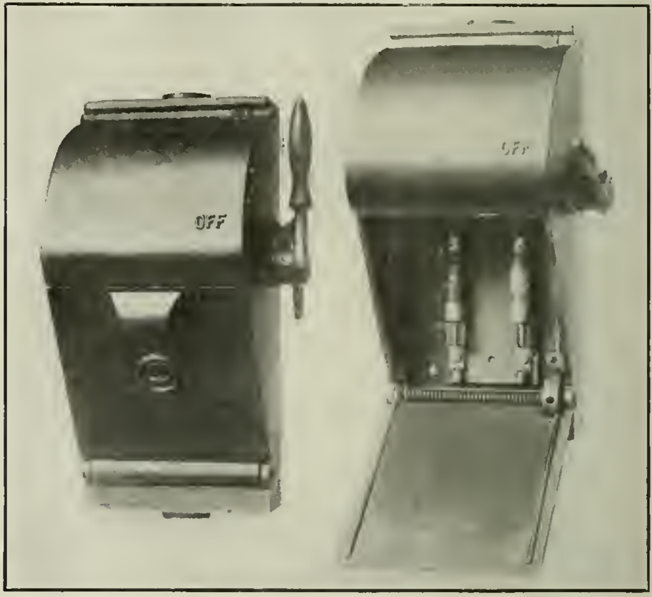
The drop-lines should be weighted at their lower ends to prevent them from becoming tangled with one another. Punched washers of sheet steel constitute excellent weights for this purpose. A washer *H* (Fig. 7) may be tied on the lower end of each drop-line *I*, as shown. The washers may be located at such a distance *J* above the surface of the ground that they can be readily reached; that is, it is not necessary or desirable to have the drop-line extend for the entire distance to the bottom of the foundation excavation. When an anchor-bolt location is to be determined, the plumb-bob line, which is provided with a hook *K* (Fig. 8), can be hung on the end of the main drop-line until the bolt location has been fixed. Then the plumb-bob line can be unhooked and carried to the next bolt location.

Safety-First Knife Switch

In all places employing men with practically no knowledge of electricity and its attendant risks, an absolutely safe switch has become a necessity. The real safe switch is one so constructed that all live parts are totally inclosed and inaccessible. Means should also be provided for preventing operation by unauthorized persons.

The switch shown in the figures, brought out by the Westinghouse Electric and Manufacturing Co., of East Pittsburgh, Penn., meets the foregoing conditions. The complete device consists of an ordinary single-throw knife switch and inclosed fuse holders mounted in a cast-iron box, with an operating handle outside the housing. The box is designed for conduit connection and has a partition separating the switch blades from the fuse holders.

The upper, or switch, compartment can be opened only by removing two machine screws and should be opened only when making connections or in case of inspection or repairs, as the switch is opened and closed by the operating handle, from the outside.



CLOSED AND OPEN VIEWS OF SWITCH

The lower, or fuse, compartment, containing the fuses and fuse holders, is the only part of the switch that need be opened, and then only to replace blown fuses. The door of this compartment is so interlocked with the switch that it can be opened only when the operating handle is in the off position and the circuit broken. Furthermore, with the door of this compartment open it is impossible to close the switch. The operating handle can also be locked with the switch in the open position, preventing tampering by unauthorized persons.

The City of Philadelphia has the distinction of having operated the first steam-pumped water system in the United States and also of operating the largest pumping plant in the world at present.

Selection of Coal and Ash Conveyors

By H. E. Birch
Structural and Mechanical Engineer, Philadelphia, Penn.

In selecting the equipment one should strike the best balance of operation, maintenance, investment and adaptability. Roller flight conveyor a desirable type. Flights over 24 in. should have two chains. Scraper conveyors limited to about 300 ft. length. Relative advantages of bucket and belt conveyors are considered.

There are four items which should control the selection of coal- and ash-handling equipment; namely, cost of operation, maintenance, interest on the investment and adaptability. These four are the constituent of the "O-M-I-A" formula, which should be applied in all cases to the bidders' competitive designs, to secure a well-balanced plant. A saving of several hundred dollars a year on power may warrant the investment in a more elaborate plant, but possibly this is offset by the greater depreciation factor or by the greater cost for labor required to operate it. All these items should be tabulated and a careful comparison made between the designs offered. The writer knows of one management corporation where the financial department makes the final selection after the engineers have secured all bids.

The benefits accruing through the installation of coal- and ash-handling equipment are many, the greatest probably being the saving effected in the wages. But this is not the only feature. There is the greater freedom from labor troubles, and the ease with which machinery can be managed, as compared with the management of unskilled workers. The unreliability of a large force of poorly paid and unskilled passers and ash men cannot be compared with the reliability of a few intelligent workmen operating well-designed and selected equipment.

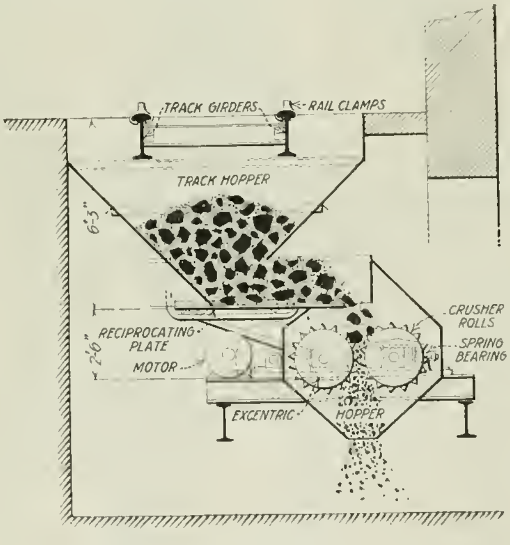

FIG. 1. TRACK COAL HOPPER AND CRUSHER

Many boiler houses have been equipped with coal- and ash-handling machinery, but many a man is often at a loss as to the type of equipment to install; and it is here that the first most serious mistakes are made.

It is desirable then, at this stage, to get the unprejudiced engineering advice of a coal-handling expert, to avoid building a monument of carelessness which will be costly to operate and maintain.

Realizing the need for service of this nature, several firms of contracting engineers have specialized in this branch, and at least one of them further attempts to build only coal- and ash-handling equipment for boiler and gas houses. To secure the most efficient plant it is often necessary to combine the wares of several manufacturers, but to successfully accomplish the desired result it is essential that the builder shall know thoroughly the uses and limitations of every standard device on the market. The result one is striving for is not necessarily the lowest first cost, but the proper balancing of the four factors—operation, maintenance, investment and adaptability.

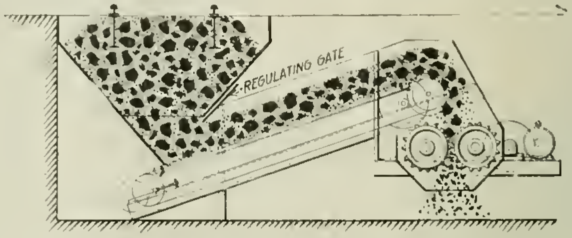

FIG. 2. ELEVATING COAL TO THE CRUSHER

There are two general ways of applying coal- and ash-handling equipment to a plant, one being to use one device for conveying both the coal and ashes, the other by providing separate machines for each duty.

The latter method is commonly referred to as the divorced system and is in use in nearly all the large Eastern power plants. The handling of ashes is usually considered as the severest duty that any conveyor may perform. The machinery must resist the destructive effect of the ashes in the chain joints, which cause rapid deterioration, and resist the distortion produced by hot ashes. Granting that the machine must be extra heavy and expensive to accomplish this result, it is unwise to use it for handling the coal, for although the ashes handled comprise but one-eighth to one-tenth of the total volume conveyed, the destructive action of the grit in the joints is in effect as long as the machine is in operation. For this reason chiefly the large stations years ago made the coal-handling machinery independent of that for handling ashes. When independent, one does not interfere with the operation of the other.

Let us assume the ideal condition of boiler-house location—that is, with the railroad track paralleling either the side or the end of the boiler house—and divide our study into three parts, as follows: (1) Unloading and crushing the coal; (2) elevating the coal vertically; (3) conveying the coal horizontally.

With the railroad track on the ground, a receiving hopper must be provided. One 10 ft. wide by 12 ft. long will be sufficient to receive the discharge from both doors of a standard 50-ton gondola. The outlet to this hopper is usually fitted with a reciprocating feeder which delivers to a double-roll crusher. The arrangement of this group is shown in Fig. 1.

Sometimes it is necessary or desirable to elevate the coal while feeding it to the crusher, when an apron feeder, Fig. 2, must be used. This arrangement is from two to three times as expensive as a reciprocating feeder, principally because the apron feeder should not be inclined more than 22½ deg., although the writer has seen one or two operating at 30 deg. This makes it a very expensive elevating device, and therefore it should not be used unless unavoidable.

Part 2 contains few machines to discuss. The leading devices used to directly elevate coal at boiler houses are all chain-and-bucket machines, varying in construction according to the use to which they are put. The oldest coal elevator consists simply of a single strand of short-pitch chain, having malleable-iron or steel buckets of cup-like form attached to it at suitable intervals, the size and spacing depending on the capacity desired, except that when they are too close, they will not dredge the coal properly. The discharge is effected by the speed at which the elevator runs, the centrifugal effect causing the material to leave the bucket. This machine is shown by Fig. 3. It is not used for first-class work or where the material is elevated very high, but for small capacities, 20 to 25 tons per hour, and where the conveyor does not work more than a few hours a day, it is economical and is to be recommended.

A far better type of machine for elevating the coal is the V-bucket elevator conveyor, Fig. 4. As built by Beaumont, it consists of two strands of steel chain with steel V-shaped buckets spaced at frequent intervals between the chains, the discharge being effected by gravity. To do this, it is necessary to change the path from the vertical to the horizontal, the usual methods of accomplishing this being shown diagrammatically in Fig. 4. The numerous paths through which this machine may operate, permit of its use in varied ways. Diagram *A* is the most common path, the horizontal run either extending for the full length of the bunker, if it is not too great, or arranging it to discharge into a scraper or belt conveyor immediately upon its assuming the horizontal path, as at *C*. The arrangement shown at *B* is often seen where this machine is handling coal for ground storage, the upper horizontal run discharging to a pile on the ground, while the lower run operates in a tunnel under the pile and reclaims the coal. This system was applied at the boiler house of the American Railways Co., Dayton, O., as shown by Fig. 5. Here, the V-bucket elevator conveyor serves both the boiler house and the ground storage, by adding the horizontal run of path *A* to path *B*. A cross-feeder is used to deliver the coal from the railroad cars to the lower run of the conveyor, first passing it through a double-roll crusher.

While the V-bucket elevator conveyor is undoubtedly the best elevating medium to use, it can be skimped, like any other good conveyor, until it is so cheaply built that good service is impossible. The chains are its "backbone," and these must be of steel for several reasons. If malleable-iron chains are used (as they sometimes are), the elevator will be subject to disastrous wrecks, for a casting is a casting and is liable to fail through various flaws to which castings are subject. A casting in tension is not the best thing in the world to depend upon. The connection of the bucket to malleable chains makes a weak point, for the connection holes are but a scant few inches apart and the buckets are liable to twist off when dredging the coal out of the feeding boot. Steel roller chains are not subject to any of these faults. Neither are the bucket connections weak, for they are attached to the pins at the chain joints. These pins should be large in diameter, say ⅞ in., and of 0.30 to 0.40 carbon steel. They should be unbushed and not attached to the chain side bars; the pin is then a floating pin, free to turn easily, thus distributing the wear over the entire surface. Cast-iron rollers are used at each chain joint, these coming into play on the horizontal runs and at turns in direction, where they are engaged by the sprocket wheels.

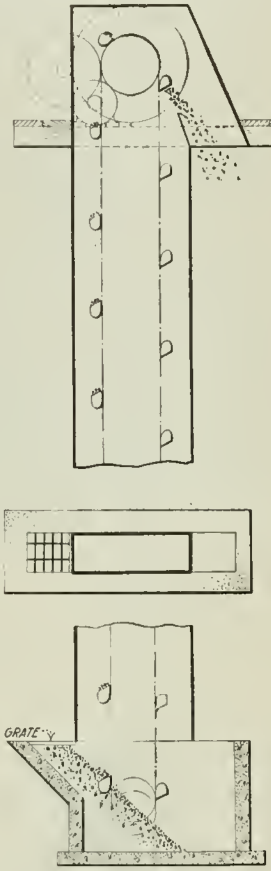

FIG. 3. SIMPLE BUCKET CONVEYOR FOR LIFTS UP TO 40 FEET

The buckets may be made of No. 10 plate as the coal does not wear them rapidly.

The trough is rectangular in cross-section, usually constructed of steel, with angle sides and a bottom plate at least $\frac{3}{16}$ in. thick. The upper flanges of the angles should have renewable wearing strips ¼ in. thick, for the roller chains to travel on.

The vertical runs are usually inclosed in steel-plate casings, No. 12 gage, and having corner angles to stiffen, besides connecting the plates. Sometimes the plates are flanged, but if this is done, look with suspicion on the rest of the equipment.

The capacity of a V-bucket elevator conveyor can easily be determined by simple arithmetic, but to avoid going through all these figures a good, conservative rule is: The cubic contents of the bucket in inches (water capacity) divided by 12 gives the tons (2000 lb.) per hour for a speed of 100 ft. per minute, the buckets being 12 in. apart. Other speeds and spacings are easily determined from this.

All sprocket wheels should have at least eight teeth, and shafts should be designed for both torsion and bending, allowing a working unit stress of not over 11,000 pounds.

A modification of the V-bucket machine is the continuous bucket elevator, which will operate in a vertical path and discharge directly over the head wheel, thus obviating the necessity of running horizontally to effect a discharge. This machine will also operate on an incline at any angle between about 45 deg. and the vertical. When discharging from the vertical position each bucket utilizes the back of the bucket in advance, as a chute, to deflect the material to the permanent chute delivering to the conveyor. Fig. 6 shows this machine in detail. The remarks concerning the V-bucket apply to this machine also, except, of course, there is no trough to convey horizontally. The last two machines are without doubt the best elevating mediums to use, regardless of to what they deliver.

The centrifugal discharge elevator should not be used except for small lifts at low capacity and where the machine does not work often.

Conveyors may be divided into two general classes—flight conveyors, and belt or pan conveyors. The first class is by far the commonest and is further divided into four types—the single-strand chain-scraper flight conveyor, the single-strand roller-flight conveyor, the double-strand roller-flight conveyor, and the screw conveyor. Figs. 7, 8 and 9 show the first three in the order named. The scraper-flight conveyor is much used for handling anthracite coal in retail yards, where breakage is a serious factor. It does not cause breakage because it is slow-moving and discharges easily through openings in the trough and also because the flight scrapes directly on the trough plate, avoiding the grinding of coal between the flight and the trough, which would happen with any of the other three types. It has been much used in boiler-house work on account of its simplicity and low cost, but it has lately been superseded on first-class work by the single-strand roller-flight conveyor, in which the chain and flights are supported above the trough by cross-spindles and rollers which travel on the channel sides of the trough. These rollers reduce the friction and the noise made by the scraper conveyor and such conveyors have greater capacity. The scraper-flight conveyor has malleable-iron flights with beveled corners to carry them over the gate openings in the trough and uses a single strand of malleable-iron chain.

The roller-flight conveyor uses a much stronger and more reliable steel chain and has steel-plate flights. The scraper flight is usually 5 in. deep and either 12 or 15 in. wide, depending on capacity, while the roller type of conveyor has flights 8 in. deep by 16 in. wide as a minimum, with 10 x 20-in. and 10 x 24-in. flights for greater capacities. Flights wider than this should not be used on a single-strand chain, for they will wobble.

Neither of the foregoing conveyors will handle run-of-mine coal, owing to the impossibility of getting the large lumps in the trough, which is obstructed by the chain in the center. For this reason the double-strand chain-roller flight conveyor is used for this purpose, and also when the conveyor is so long or so large that two chains are necessary to properly take the stress. Flights over 24 in. wide should have two chains, as already mentioned.

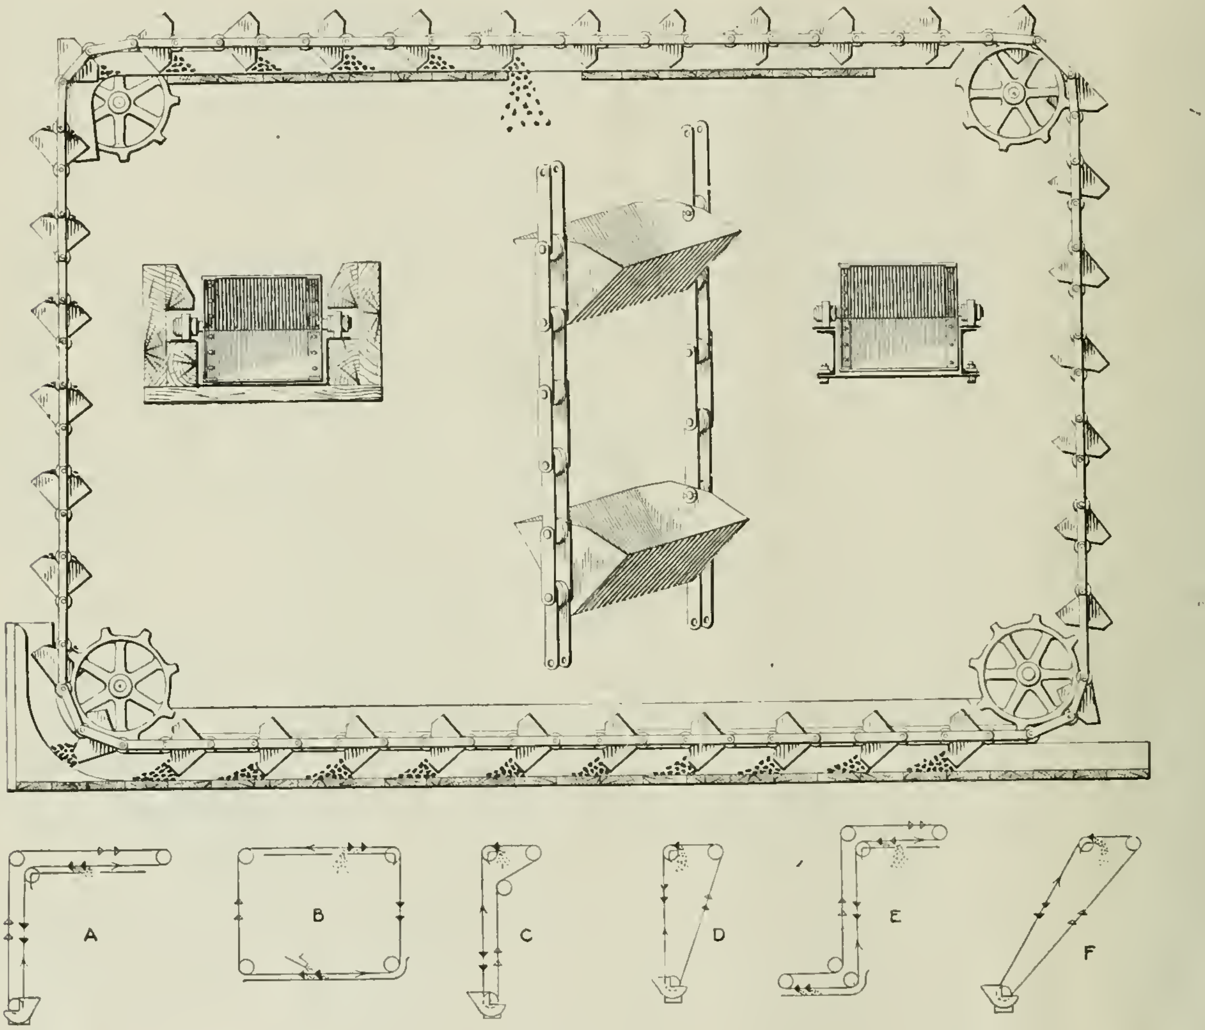

FIG. 4. V-BUCKET CONVEYOR AND ITS APPLICATIONS

A double strand of chain is used when it becomes necessary to bend the conveyor from an inclined run to a horizontal one, making a "hump." With a single-strand roller-flight conveyor, the stress imparted to the cross-spindles by the chain would probably bend them, although under small stress the resulting bending movement on the cross-spindle would be almost negligible. A scraper conveyor, where the flights scrape directly on the trough, could not be used this way, but would have to be broken, the conveyor on the incline discharging the coal into the horizontal conveyor.

SCREW CONVEYOR UNSUITED TO COAL

Troughs for these conveyors should be at least $\frac{3}{16}$ in. thick and should be bolted to the supporting channels to facilitate renewals. The remarks concerning chains, sprockets and shafts, previously made, apply here. The fourth type, the screw, mentioned for the sake of completeness, is not much used for conveying coal, being mostly used for grain and cement. The usual application to a boiler house is where pulverized coal is used. They consist of a blade wound spirally around a central shaft, the whole revolving in a U-shaped trough. The frictional losses are so large and the danger of breaks due to foreign material jamming at the shaft hangers are their bad features. They are very cheap, however, and this perhaps is the reason they are seen in boiler houses.

As to the second main class of conveyors, belts and pan arrangements, the former is by far the most popular; the latter can, in fact, be dismissed from coal handling at boiler houses, except for short feeders carrying run-of-mine coal to the crusher.

As a conveyor, it has two difficulties, one being the high cost and the other the impossibility of securing a discharge, except over the end of the conveyor.

The rubber belt has three advantages, but only two apply to boiler-house outfits. The first is lower power consumption and the second quietness of operation. The third is that they convey materials 1000 ft. or more, while scraper conveyors are limited by good practice to about 300 ft. Manifestly the length of the average boiler house does not exceed the maximum length of the flight conveyor.

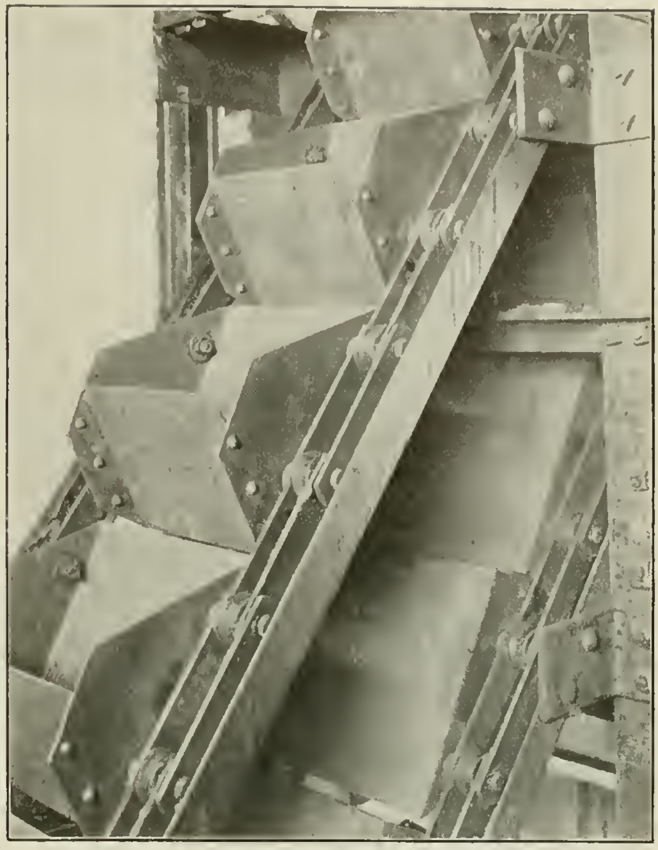

FIG. 6. CONTINUOUS BUCKET ELEVATOR

A belt-conveyor installation has several disadvantages which perhaps outweigh the few advantages. It is not easy to load and requires a ponderous device to

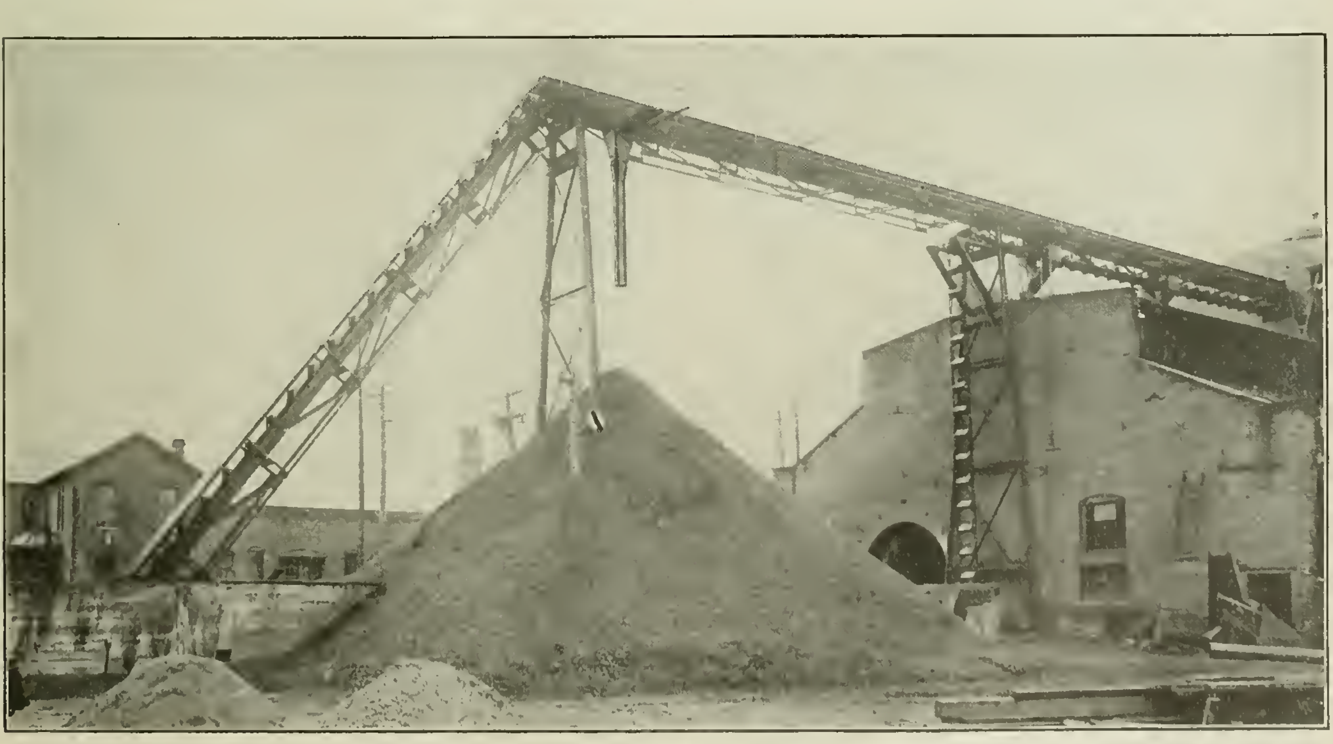

FIG 5. BUCKET CONVEYOR AT THE AMERICAN RAILWAYS CO., DAYTON, OHIO

effect a discharge. It is hard to load because of the difficulty of delivering the coal to the belt at the same speed and in the same direction as the belt is running. This requires side guard plates extending along the length of the belt for a distance of four or five feet, as the difference between the speed of the coal and the belt at the point of impact causes a great deal of splashing. This loading condition is aggravated by the necessity of depressing the end of the belt conveyor, until it operates on an angle of 18 to 20 deg. This is due to the belt tripper, for when this device is at the loading end of the conveyor, the belt would rise directly from the end pulley if the belt was not depressed, and would be cut to pieces by the previously mentioned side guards. This is avoided by depressing the belt, but the danger of the guards sagging and cutting the belt is always present.

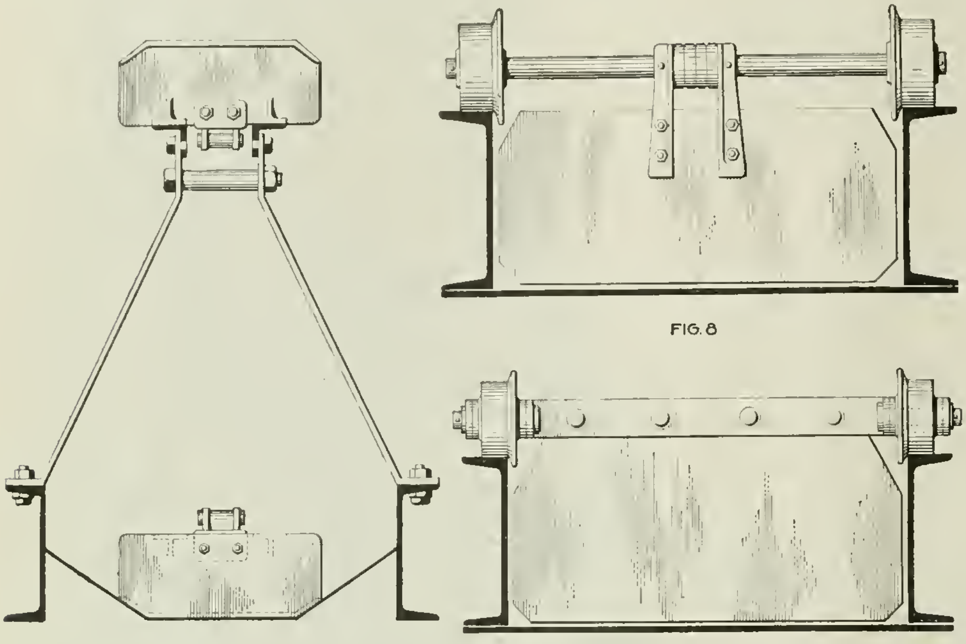

FIG. 8

FIG. 7

FIG. 9

FIGS. 7 TO 9. TYPES OF SCRAPERS FOR FLIGHT CONVEYORS
Fig. 7—Thick edge flight. Fig. 8—Square-corner roller flight. Fig. 9—Double-strand roller flight

Should the belt be ruined suddenly in this manner, it means a long wait until a new one can be secured, for it is expensive to keep a new belt in stock and even then run the chance that it will harden before it is needed.

Wear on Rubber Belts

Belt conveyors require more attention than flight conveyors. The idlers are rather delicate mechanisms and require constant attention, otherwise they will not turn and the belt simply scrubs over them, wearing it out and consuming more power. Also, when the run is short, they wear out quickly, the wear being due to the impact of the coal on the belt at the loading point. It is obvious that in a conveyor twice the length the impact is distributed over twice the belt area of the shorter one for a given quantity of coal handled. Remember that a flight conveyor can be wrecked badly and put in service again by a local blacksmith, but a belt conveyor is dependent on the factory for repairs.

A typical belt conveyor installation is shown by Fig. 10, this being a view over the coal bunker at the boiler house of the Norton Co.,[2] Worcester, Mass. As to the first cost of the belt conveyor compared with the flight type, this varies according to the length. A belt conveyor without the tripper is more costly than the bevel-scraper flight type but cheaper than the roller types, but when the tripper is added (it is necessary) the belt is the most expensive one to use. If the length of the short conveyor is doubled, the cost is not, for one does not need another expensive tripper and then the belt is cheaper than the flight conveyor, but only slightly.

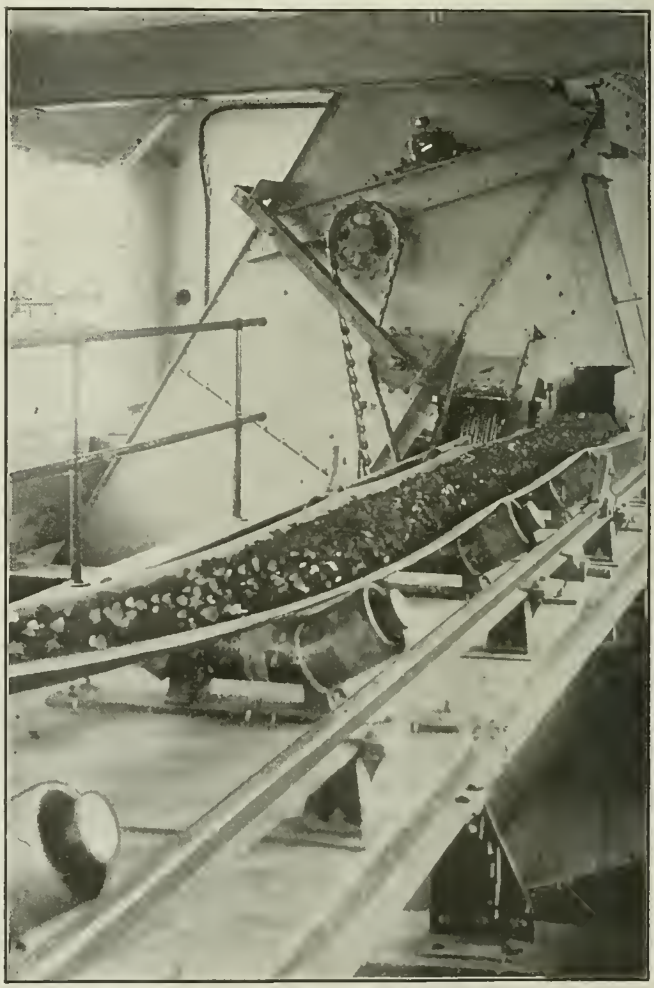

FIG. 10—BELT CONVEYOR, NORTON CO., WORCESTER, MASS.

It is always well to bear in mind that low first cost often means high maintenance charges, as pointed out previously. The wear and tear on coal and ash conveyors is especially severe, and care in their selection is paramount.

---

The Electrical Study Course—Direct-Current Armature Construction

The development of the direct-current armature core is briefly described, and some of the defects in the earlier types are pointed out.

DIRECT-CURRENT armatures may be classed under two general types—ring and drum. Both types get their name from the shape of the core. The core of the ring type consists of an iron ring about which the coils are wound, as shown in section in Fig. 1. In the earlier type of machines the ring-armature construction was used to considerable extent, but it has since been practically abandoned. Some of the objections to this type of construction are that only one side of the coil is effective in generating voltage. Why this is so is explained in Fig. 2, where a ring armature is shown between the poles of a two-pole frame. It will be seen that all the lines of force are only cut by the conductors on the outer surface of the core. Therefore, only these parts of the coils are effective in generating voltage.

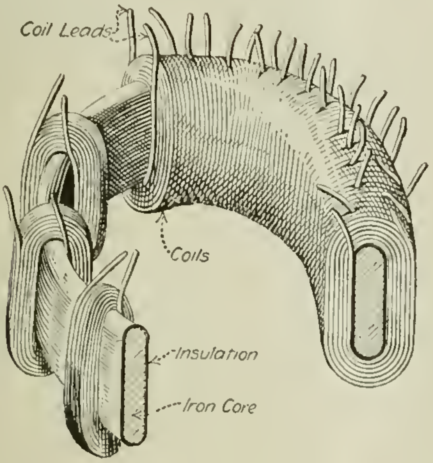

FIG. 1. SECTION THROUGH RING ARMATURE

There is always a leak across the space in the center of the ring; that is, a small percentage of the lines of force, instead of flowing around through the core, take the path across the space in the center of the ring, as indicated in Fig. 2. The conductors on the inside of the ring cut the lines of force that leak across from one side of the ring to the other, in the same direction as the conductors on the outside of the core. Consequently, a voltage will be induced, in the same direction, in the side of the coil on the inner periphery of the ring, as in that on the outer.

In Fig. 2, consider the ring revolving in the direction of the curved arrow; then under the N pole the voltage in both sides of the coils is up through the plane of the paper, and under the S pole it is away from the reader. In either case it is evident that the voltages generated in the conductors on the outside and inside of the ring oppose each other. Since only a small percentage of the flux leaks across the ring, only this percentage will be cut by the conductors on the inner periphery, and the voltage generated in these conductors will be only a small percentage of that in the outside, the difference between the two being the effective voltage in the coil. The foregoing is another objection to the use of a ring armature.

Another difficulty is in winding the coils on the core, they have to be wound in place by hand. On account of having to thread the coils through the center of the core, the placing of the winding is a somewhat long and tedious job. These and other structural and electrical defects have caused this type of construction to be practically abandoned in favor of the drum type of armature.

The core of the early types of drum armatures consisted of a cast-iron cylinder keyed on a shaft, as in Fig. 3. Pieces of fiber were placed in small slots in the corner of the core, as shown, to facilitate the spacing of the coils around the periphery. One of the serious objections to the use of solid cast-iron cores was that they had heavy current generated in them, which not only greatly increased the temperature for a given load, but also loaded up the machine.

The foregoing will be understood by considering Fig. 4, which shows an iron core between the N and S poles of a magnet. If the cylinder is revolved in the direction of the curved arrow, then the side of the core under the N pole will be cutting lines of force in a right-hand direction and will have a voltage induced in it that will tend to cause a current to flow toward the reader. On the other hand, the side of the cylinder under the S pole is cutting the flux entering the pole in a left-hand direction, and consequently has a voltage induced in it that will tend to cause current to flow away from the reader. This is just what we found out about a loop of wire revolved between the poles of a magnet in the last lesson.

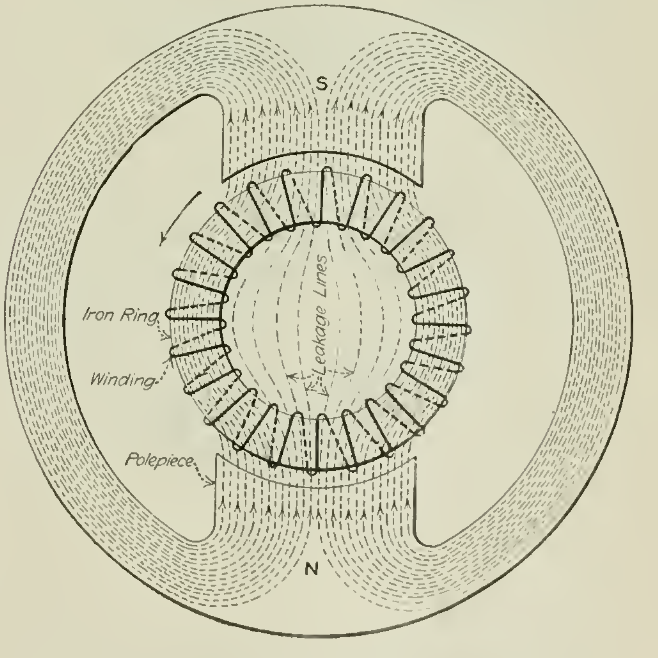

FIG. 2. MAGNET FLUX IN RING ARMATURE

The condition in Fig. 4 is such that the voltage generated in one side of the core is assisting that in the other side. Consequently, a current will flow around in the core, as indicated by the dotted loop and arrowheads. This current is entirely independent of the winding on the armature and external circuit, and just as long as the field poles are excited and the armature revolved, a current will circulate or eddy around in the core. Since these currents circulate or eddy around in the core as water in a whirlpool, they are called eddy currents.

These eddy currents represent a distinct loss, not only in capacity, but also in the power used to drive the generator or motor. Eddy currents increase the temperature of the machine, consequently reduce the useful temperature range. For example, if the normal no-load temperature of the armature, if eddy currents did not exist, is 80 deg. F., and the maximum temperature that the machine can be operated at is 212 deg. F., then the machine can be loaded to the extent that would increase the temperature from 80 to 212 deg. F., or 132 deg. But on the other hand, suppose that the no-load temperature of the armature, due to eddy currents, is increased to 100 deg. F.; then the machine is only capable of carrying a useful load that will increase the temperature from 100 to 212 deg. F., or 112 deg. Consequently, the useful capacity of the machine under the latter conditions will be reduced.

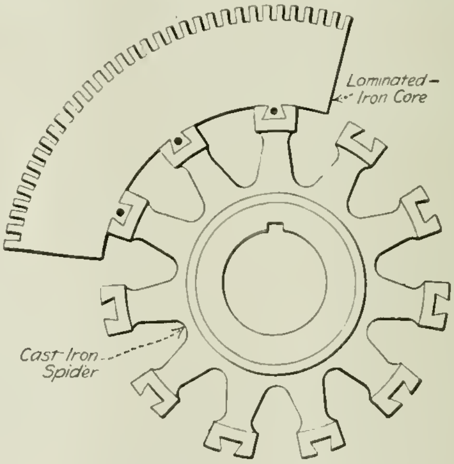

Fig.10

FIGS. 3 TO 10. DIFFERENT TYPES OF DRUM-ARMATURE CONSTRUCTION

It should be kept in mind that the amount of load that can be carried by any electrical machine is limited by the heating effect of the load. For a machine insulated with fibrous material this temperature must be limited to about 212 deg. F.

Another effect of eddy currents in the armature is to increase the power necessary to drive the machine. This will be understood by referring to Fig. 4. Here the generated current due to the core revolving, in the direction indicated by the curved arrow, in the magnetic field is indicated by the dotted loop and arrowhead in the core. Current flowing in the magnetic field will cause a pull to be exerted upon the core, just as explained for a single conductor carrying a current in a magnetic field in the lesson in the Dec. 4 issue.

The direction of the pull on the core may be determined by the rule for the direction of a motor, or, in Fig. 4, it will be found that the eddy currents in the core will produce a pull against the direction of rotation.

In other words, we assume that the core is revolving in the direction of the curved arrow, but the direction of the eddy currents in the armature core produces a pull in the opposite direction. Consequently, the source from which the armature is driven will have to develop power enough not only to drive the armature to supply its useful load, but also to overcome the effect of the eddy currents in the core.

ELIMINATING EDDY CURRENTS

From what we have just seen, it is apparent that, if possible, these eddy currents should be eliminated. This is done to a very large degree by building up the armature core of thin sheets of soft iron or steel, as in Fig. 5. These sheets are from 0.01 to 0.03 in. in thickness. In the early type of machines the oxide on the surface of the sheets was very largely depended on to insulate one from the other. Although this did not completely insulate the disks from each other, it offered considerable resistance to the flow of the current in the core parallel with the shaft. In the modern machines the iron sheets that the core is made of are given a very thin coat of insulating varnish on one side, which practically entirely eliminates the effect of eddy current.

On account of the insulation the core has to be made slightly longer than a solid core would be, in order to get in the same volume of metal. Armature cores that are built up of thin sheets of iron are said to be laminated, and the sheets are frequently referred to as the laminæ. The cores of small-sized armatures are keyed to the shaft and held between cast-iron shrouds, or retaining plates, which are held in place by a nut threaded on the shaft, as in Fig. 5, or by bolts run through the core.

OBJECTION TO SMOOTH-CORE ARMATURES

With these smooth-core armatures, the winding had to be placed on the surface of the core. There were several objections to this, such as the coils, being on the surface of the core, were exposed to mechanical injury; sufficient space must be allowed between the armature core and polepieces for the winding. On account of the comparatively long space between the armature core and polepieces, considerably more power is required to be expended in the field coils to cause the line of force to flow from the latter to the former, or vice versa, than if the core was as near the field poles as would be consistent with good mechanical construction.

Another serious objection is that the coils are wound on the core by hand, one coil at a time. Consequently, the coils can only be removed the reverse of the way they are put on. Therefore, if two or three coils are injured in the winding, it generally means that the whole winding must be removed and a new one put in its place, whereas, if the coils are made up separately, as in modern machines, the injured coils can generally be removed and replaced by new ones, by removing only a small part of the total winding.

All the difficulties cited are practically eliminated by slotting the core as in Fig. 6. The core is built up of thin sheets as in Fig. 5, but instead of the outer periphery of the disk being smooth as in Fig. 5, it has slots cut in it. These slots take different forms, some of which are shown in Figs. 7 to 9. However, when the coils are made up and insulated before they are put on the core, the slots in the core must be open at the top, as in Fig. 8 or 9. Where the coils are made up separately and insulated before placing on the armature, it is evident that the winding is not only more easily put in place, but can be better insulated.

The placing of the coils in slots in the armature core protects them from mechanical injury in case the bearings wear and allows the armature to rub on the polepieces; it also allows the space between the core and the field poles to be reduced to a minimum consistent with good mechanical construction. Consequently, the magnetic field is set up with a minimum power expenditure in the field coils. In the larger-sized armatures a cast-iron spider, as it is called, is keyed to the shaft and the laminated core built upon the spider, as in Fig. 10.

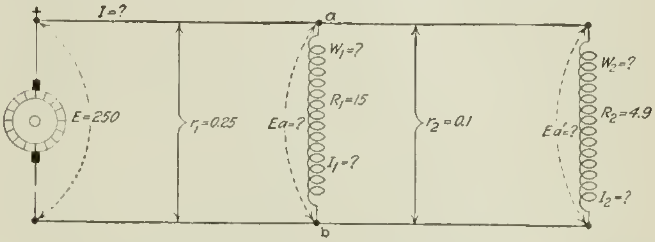

FIG. 11. COMPLEX CIRCUIT

The layout of the study problem is given in Fig. 11. The resistance from a at R_1 around through R_2 to b at R_1 is $R'' = r_2 + R_2 = 0.1 + 4.9 = 5$ ohms. This resistance of 5 ohms is in parallel with $R_1 = 15$ ohms, and the joint resistance of R'' and R_1 is

$$R' = \frac{1}{\frac{1}{R''} + \frac{1}{R_1}} = \frac{1}{\frac{1}{5} + \frac{1}{15}} = \frac{1}{\frac{3+1}{15}} = \frac{15}{4} = 3.75 \ ohms$$

The total resistance of the circuit is $R = r_1 + R' = 0.25 + 3.75 = 4$ ohms. Then $I = \frac{E}{R} = \frac{250}{4} = 62.5$ amperes. To cause a current I to flow from the armature through the resistance of the two conductors r_1 will require a voltage $E_d = r_1 I = 0.25 \times 62.5 = 15.625$. Therefore, only a voltage $E_a = E - E_d = 250 - 15.625 = 234.375$ volts is available at R_1 to cause a current to flow through the circuit. The current that will flow through R_1 is $I_1 = \frac{E_a}{R_1} = \frac{234.375}{15} = 15.625$ amperes, leaving a current of $I_2 = I - I_1 = 62.5 - 15.625 = 46.875$ amperes flowing through R_2. To cause a current $= I_2$ to flow through the connecting wires between R_1 and R_2 will require a voltage of $E_d = r_2 I_2 = 0.1 \times 46.875 = 4.6875$. Hence, $E'_a = E_a - E_d = 234.375 - 4.6875 = 229.6875$ volts. The current flowing through R_2 is also $I_2 = \frac{E'_a}{R_2} = \frac{229.6875}{4.9} = 46.875$ amperes, which checks with the other calculation, showing that the work is correct. The total watts $W = EI = 250 \times 62.5 = 15{,}625$; total kilowatts $= \frac{W}{1000} = \frac{15{,}625}{1000} = 15.625$; and the total electrical horsepower $= \frac{W}{746} = \frac{15{,}625}{746} = 20.9$ horsepower.

A load consisting of 37.5 hp. of motors, allow 3.8 amperes per horsepower, and sixty-four 75-watt lamps is supplied over a two-wire feeder, 475 ft. long. If the voltage is 240 at the source, what size will the conductors have to be to maintain 235 volts at the load end of the feeder when transmitting the total load? If the load is used on an average of 6.5 hours per day for 26 days, find the cost of power at 7.5c. for the first 800 kw.-hr., 6c. per kw.-hr. for the next 1000 kw.hr. and 4.5c. for the remaining kw-hr. consumption. The kilowatt-hour meter is located at the load end of the feeder.

Testing for Ammonia in Brine

Leaks in coils carrying ammonia and surrounded by brine or water are difficult to detect and usually continue until the brine or water has the odor of ammonia. If one suspects that coils are leaking, a sample of the brine may be drawn into a test tube or other receptacle (glass preferred) and a few drops of Nessler's reagent added. If the brine contains a little ammonia, it will take on a yellow shade; if there is much, the brine will turn brown when the reagent is added.

Nessler's reagent may be made as follows: Dissolve 17 grams of mercuric chloride in 300 c.c. (approximately 10.6 oz.) of distilled water. Next dissolve 35 grams of potassium iodide in 100 c.c. (about 3.5 oz.) of distilled water. Add the potassium-iodide solution to the mercuric chloride and stir until a red precipitate is formed. Now add 120 grams of potassium hydrate dissolved in 200 c.c. (about 7 oz.) of water. As the solution will get hot when the potassium is added, it should be allowed to cool before being stirred. When cool, pour in distilled water until there is 1 liter (about 1 qt.) of solution. Next add more mercuric chloride until a permanent precipitate again forms.

The liquid should stand until the precipitate has settled and left the solution clear, after which pour it into a dark-brown or blue glass-stoppered bottle, and keep it in a dark place.

Handy Gate Lock

It is frequently advisable to prevent visitors to power plants from having free entrance to the operating floor. An engineer may be busily engaged on work that requires his undivided attention only to be interrupted by the presence of some intruder who has wandered into the plant, there being nothing to prevent him from roaming at will about the premises. It does not cost much to erect a pipe railing covered with wire netting at the inside entrance of the plant, with a gate which is fastened by a lock that can be operated only by an attendant from the inside.

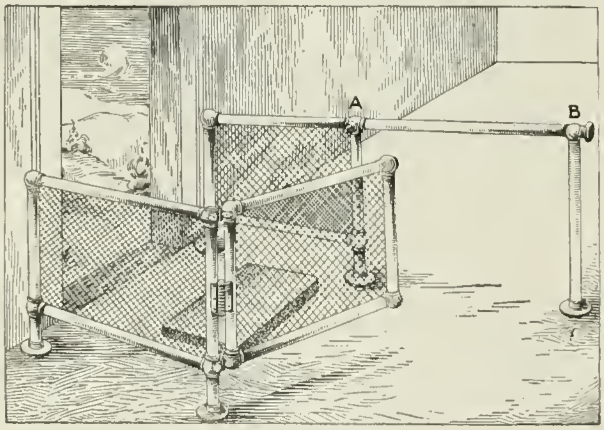

FIG. 1. LOCKING GATE FOR POWER PLANT

Such an arrangement is shown in the illustration. The locking point is at *A*, Fig. 1, and the lock can be operated only by turning the handwheel at the end of extension *B*. Details of the locking device are shown in Fig. 2. The latch *D* slides in the pipe connection and the end enters an opening in the joint at the top of the gate frame. The bolt is fitted with a pin *E* and is kept in the locked position by the spring *F*. Engaging with the pin *E* is a slotted block *G*, which is secured to the rod *H* and is fitted with a handwheel *B*. When it is desired to admit passage through the gate, the handwheel *B* is turned toward the left; this will move the pin *D* from the gate and permit of its being opened.

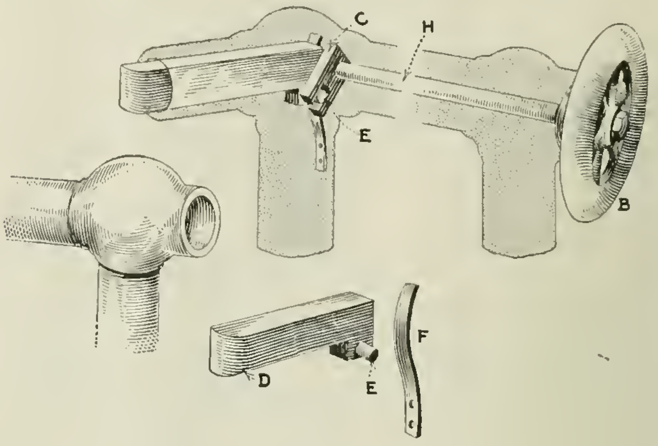

FIG. 2. DETAILS OF THE LOCKING DEVICE

Spring hinges are used on the gate, and after it has been opened it will spring shut and automatically lock, the bolt end acting the same as the catch on an ordinary house door, the end being made at an angle so as to slide over the end of the gate when it is closing.

The shortage of fuel of all kinds in Denmark has kept the large users of power anxiously looking toward Sweden for electric power, which at times they have in abundance. According to *Commerce Reports* the water power now developed in Sweden seems not to furnish any surplus power beyond the country's own needs during dry seasons, but during about half of the year there is generally a considerable exportable surplus. The villages in the northern part of Sjælland have been obtaining some small quantities of electricity by cable across the sound, and occasionally some of it has been used in Copenhagen. Now arrangements are being made to lay additional cables across the sound, with the intention of furnishing the street-car service of Copenhagen and Frederiksberg with a large amount of power. The difficulty in obtaining copper cables and electric transformers is delaying this work. It is expected that most of the power will come from the Laga Lakes and the Trollhättan Falls in Sweden.

Industries making war materials and supplies will of course get coal even if those producing luxuries get none. We have the paradox of the engineer engaged in war worrying less than he of the antique furniture factory.

Editorials

Chances for Promotion in Power Plants

IT IS no exaggeration to say that there never was a time in the history of power-plant service when the prospects of promotion were better than they are today. There are many reasons for this, but among the most important are the vital necessity power has become for war and peace tasks alike and the sure and sustained demand for low-cost energy which will be felt in many parts of the world after hostilities have ceased. To overlook present difficulties in power-plant operation would be a mistake; conditions are very trying with regard to fuel supply, prices of all materials and of labor in a great number of stations. In a number of cases central stations have taken over the service of independent plants, but it by no means follows that even a major share of these plants will always find purchased energy cheaper than their own production. Costs are rising in the central station itself, and it is a daring company indeed today which will make a new power contract without a coal clause in its heart which in a measure seeks to offset increasing fuel prices by additions to the unit energy rate, and vice versa.

The great majority of our productive industries must continue to function, war or no war. "Business must go on" is a true expression of the situation. The war, it is obvious, brings many changes to industry. No small number of engineers are serving their country at the front or in immediate preparation for active military or naval duty, but thousands upon thousands are quietly doing their bit at the old stand, working hard to overcome the handicaps the present supply prices and shortages impose and striving to prepare themselves for larger responsibilities. The duties of civil life must be performed, and the work behind the firing lines could not continue without the loyal service of the coal passer, the engineer, the switchboard operator, pumpman, repairer and all the rest of the staff upon which continuous and efficient production of high-class energy depends. Now the changes which the war brings carry into the industrial world in countless places and in unexpected ways. The war must be won, no matter what the cost to ourselves and our allies. Shifts from one plant to another take place; sometimes the engineer is obliged to lose his hold upon a most satisfactory position; but in the long run, in fact almost in the short run, things will work out to his interest if he makes the most of his opportunities. The world cannot lie back and simply refuse to take advantage of all skilled and highly trained men in the engineering field not called to direct military service; it must utilize such men to the full, even if a period of readjustment accompanies the change from one service or post to another.

This is a time when it is good to realize the vast amount of work which lies ahead of us all—not only now but during the reconstruction period to follow the war, for it is inconceivable that such a period will not come. The peculiar talents of the engineer will be in demand indefinitely, so far as we can see. Now is the time, then, to realize the sound fundamental conditions of the power-production industry as related to the allied world's economic needs, and to make personal devotion to the cause of world efficiency one's watchword. Specific opportunities for promotion may be out of present vision, but we are now in a great transition period and those opportunities are bound to come to him who is prepared to meet the new professional standards, or at least who holds the larger outlook and deeper training for the coming years.

Conservation of Fuel

THE Government has asked that every true American conserve as much as possible the fuel which is so necessary to the effective conduct of the war. It should be considered the patriotic duty of every engineer and fireman to see that the last elusive B.t.u. in the coal he burns, is harnessed and made to do its share of the work his plant is engaged in.

There is little doubt but that many seekers after personal gain will attempt to use this plea of the Government to further their own selfish interests.

We may expect a revival of ash-burning schemes and similar fakes, as well as a greater effort on the part of those who sell more legitimate apparatus, intended to economize fuel, to increase their sales.

While every device and improvement that will reduce coal consumption is exceptionally desirable at this time, production is hampered by lack of man-power, transportation is clogged, and the engineer should realize that the saving he can make without the outlay of money is the kind that counts most.

If your employer's money is spent without a very considerable return in the way of fuel saving, the ends of the Government are more certainly defeated than if no change was made. Every cent saved in the purchase of nonessentials and applied to the purchase of necessary things makes a balance of two cents on the right side of your plant account. This is the kind of saving that will do the Government, as well as the "Boss," the most good at this time. Such saving may be made by the proper use of the tools at hand. The common ways that fuel is wasted in the boiler room are by improper firing methods, dirty boilers and leaky settings and piping. These wasteful defects may all be corrected in the average plant without any considerable outlay in money. Generally, where two or more boilers are used, the failure to balance the draft properly between them is a serious source of waste.

It is a simple matter to see that the dampers are adjusted so that the proper amount of fuel is burned under each boiler to make it do its share of the work in accordance with its size. In connection with the efficient operation of boilers it should be remembered that while it is necessary that the boilers be kept clean internally—and that this is also necessary from the standpoint of safety—the greatest returns in fuel saving are secured from the careful cleaning of the surfaces in contact with the gases. This is especially so with those surfaces in contact with gases of lower temperature, such as the tube surfaces in the horizontal-tubular boiler. Soot is liable to collect on such surfaces, and there are probably few substances that are better nonconductors of heat than soot. Clean the tubes out at least once every day and watch results at the coal pile. This is hard, dirty work, but you will derive satisfaction from the fact that you are performing a patriotic duty in saving fuel without an outlay of money, which counts at both ends. Tell the "Chief" of your patriotic ambition to save fuel in this time of need, and he will no doubt coöperate with you and see that you are given necessary assistance.

Must Efficient Management Be the Most Expensive?

IN A recent hearing before one of the public-utility commissions of New England the opponents of a rate increase urged that a more efficient and less expensive administration would solve many of the problems under consideration.

The relation between efficiency and cost of management is a question of much interest. It comes directly home to the operating executive of the power plant, and many an engineer knows that his employer's ideas on this subject are in need of revision.

In a nutshell, the issue raised is whether the cheapest service is the best. Translated into power-plant engineering, it is simply a question of getting service out of the station of lowest cost and out of the poorest-paid staff, and deluding oneself that the combination represents maximum efficiency. There are low-paid station organizations accomplishing wonders with equipment that represents anything but the most modern designs, it is true. There are also administrations that may well be looked upon as extravagant by the less fortunately circumstanced. Admit all this, and still the fact remains that A-1, first-class, top-notch service costs real money. Here is the point: That service is the best which costs least *per unit*, taking *all* the factors into account—not merely operating expenses, but fixed charges, and in addition to these, quality of output with respect to regularity and reliability.

Now, management is only one factor, though a most important one, in this total cost, in this minimum unit cost which represents the best performance of the investment and its personnel. In a narrow sense efficient management costs more than cheap administration; in the long run and in a broad sense it costs far less. It all comes down to "making good." If by paying higher salaries and wages the cost of production, taking all items into account, decreases per unit of output, there can be but one answer to the question at the head of this article, and that answer is "No." On the other hand, if the unit cost of output is found in a given case to be higher *in toto* with a poorly paid staff and correspondingly lower total payroll, the answer is: "Pay enough to secure and maintain an efficient administration; measure results not by total outlay but by cost per unit, and everyone will be better off." Maximum efficiency, of course, is costly, but if the conditions demand maximum efficiency or the nearest approach to it that can be realized, anything less may be utter extravagance, or money thrown away.

Giving Credence to Rumors

RUMORS are rife these days regarding mismanagement in this, that and the other thing, all of which are detrimental to the country as a whole regardless of whether they are true or not.

In the Eastern States the public recently indulged in excitement because of the rumor of a salt shortage, which does not exist. The real shortage of sugar, the cause of which is debatable, has given the rumormonger an opportunity to howl calamity and foster in a small measure discontent in the minds of many householders; the coal shortage has produced a state of mind in others bordering on a panic; and so it goes.

There will doubtless be other real and imaginary shortages that the American public will experience before the war is over, and it is about time that we began to realize that our manner of living must be changed to meet the conditions brought about by our country entering into war against Germany. What cannot be cured must be endured in this country, as it is in others that are not so well off as ourselves.

An American just returned from France, after serving with the French at the front, said that he had heard more grumbling over a little sugar shortage since returning to America than he had heard regarding conditions in general during his entire service in France. That the American people are gullible in some respects is well known, and they are prone to swallow almost anything that is put before them without waiting for the proof of the pudding.

For instance, public statements have been made to the effect that anthracite coal, of which there has been a real shortage in New York and other cities, has been delivered to the army cantonments in excessive supplies and that it is being wasted. As a result of these reports the Anthracite Operators' Committee has made an investigation through its secretary, E. W. Parker, who visited Camps Merritt, Dix and Upton, and his findings are given in a statement signed by F. W. Warringer, Chairman of the Operators' Committee, as follows:

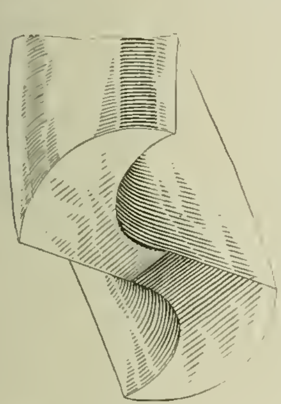
> Referring to reported waste of anthracite, Mr. Parker says that the quantity of coal wasted has been negligible, and where it has been scattered some distance from the car, care has been taken to gather it up and reshovel it into the piles.
>
> Mr. Parker reports that only on one occasion at any of the camps, and then owing to a washout on the spur track leading to the cantonment, was there any congestion in the delivery of anthracite or the return of empty cars. His judgment is that anthracite is being delivered at the cantonments in no greater amounts than is necessary nor faster than it should be to keep a safe forward supply, also that it is being received with regularity.

The probabilities are that many such rumors will, when investigated, prove to be without foundation, and all Americans should give scant attention to them, as they are doubtless started with a purpose on the part of someone who is interested in creating discontent in the minds of the people.

Correspondence

Drilling Metal by Hand Power

Occasions frequently arise in the course of an engineer's duties when holes must be drilled by hand for all sorts of purposes, from an air vent in a pipe or radiator to drilling out a broken stud. The job can often be finished with a breast drill or an ordinary bit brace before the conventional ratchet and "old man" equipment can be rigged up—and without any great physical effort. The one thing necessary is to drill a small hole first, followed with the large drill and if necessary with intermediate sizes until the finishing size can be operated easily. The philosophy of the thing is simply that the center or flat part of a drill cannot cut the metal; it only scrapes it off when great pressure is exerted to force it down and the larger the drill the wider this flat point is. Therefore if a hole is first drilled that is equal in diameter to the width of the "nose" of the larger drill, the pressure required to make the drill "bite" will be comparatively little. Try it and see.



END VIEW OF TWIST DRILL

Another advantage of drilling a small hole first is the fact that a drill cannot cut "oversize" when not ground evenly, as it otherwise will. As to the reason for choosing a brace against a geared breast drill, the latter is usually geared for speed and the drill cuttings are necessarily thin—mere scrapings—because the turning power is limited, but with a long-sweep brace the leverage is greater and heavier chips can be cut out. In other words, it takes more strength to remove the metal in pulverized form than in chips of reasonable size. In using a ratchet drill about one-third of the time and effort is lost on the return or non-cutting stroke. A geared drill—geared down—is a whole lot better because the full sweep is utilized. A small blacksmith drill press can often be utilized if bolted to a light timber of convenient length to block in place.

Frequently an old flat drill is considered good enough for use in a ratchet, while twist drills are cheap and so much better that they should be procured if possible—at least up to a reasonable size—and the flat drill used only for large or odd-sized jobs. J. LEWIS.

New York City.

Ammeters Were Reversed

Indicating ammeters and voltmeters of the permanent-magnet type will indicate the polarity of the voltage that is applied to them. This is because a reversal of the external polarity reverses the flux of the movable coil, but does not reverse that of the permanent magnet. Therefore a reversal of the polarity of the source reverses the throw of the needle for the same reason that interchanging the field or the armature connections of a direct-current motor reverses the direction of rotation of the armature. Meters of other than the foregoing type will not indicate the reversal of the polarity of the source to which they are connected, for such changes reverse the fluxes of both the controlling and the deflecting fields, leaving the polarity relations of the two fluxes the same as they were before the reversal, for the same reason that reversing the line connections of a d.c. motor does not affect its direction of rotation.

If a direct-current generator in normal operation has imposed upon it suddenly sufficient overload to greatly reduce the speed of its prime mover, the polarity of the generator may become reversed. The reason for the reversal is that at low speed and heavy current, the voltage on the shunt field is low, which decreases the flux from the field poles where the reaction of the heavy armature current is able to reverse the magnetism of the polepieces, before the circuit-breaker acts to relieve the situation.

An operator complained that the two ammeters used with two generators that were operated in parallel had reversed, although the voltmeter used for paralleling the machines had not. An inspector investigated and found that the voltmeter was of the separately excited type while the ammeters were of the permanent-magnet type; therefore what had happened was to be expected under the circumstances, which were as follows: A few days previous the generators had been subjected to an overload so heavy that the governors had tripped out the waterwheels driving the generators. It was then that the polarity of the generators had been reversed and for the reasons just given. As there was no objection to the reversed polarity, the ammeter leads were reversed on the instrument shunts in order to make the needles deflect in the proper direction.

Brooklyn, N. Y. E. C. PARHAM.

[Where the polarity of a direct-current generator is reversed when a heavy short-circuit occurs, it does not necessarily follow that the reversed polarity is due to armature reactance alone. When a generator slows down, which is supplying a motor load that has considerable inertia, the mechanical load drives the motors as dynamos, and they in turn supply a reversed current through the series-field windings of the generator, which in many cases is heavy enough to reverse the polarity of the latter.—Editor.]

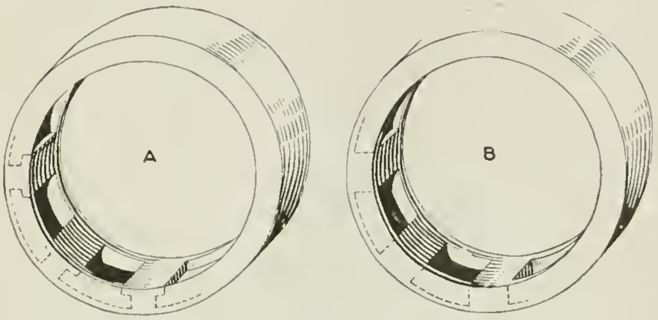
Publicity About Turbine Accidents

Referring to the article by C. H. Camp regarding turbine accidents, published in *Power* for Nov. 20, 1917, I wish to state that he has been misinformed about the Port Huron Electric Co. No such accident ever occurred to my knowledge, and I have been here for some time.

Port Huron, Mich. D. J. RICHARDS.

Poorly Designed Bull Ring

It was recently necessary to put a new bull ring in an engine, and when it arrived it was found to be made about as shown in the sketch *A*. The skeleton form was designed for lightness and was made with cross-bridges to support the keys and to strengthen and stiffen the ring. It will be seen that between the bridges pockets are formed which extend under the top of the bridge about ¾ in., thus making a receptacle for scale and core sand, which is difficult to remove. Although care was taken to clean out these pockets by means of chisel, scrapers, brushes and air blast, trouble developed soon after the engine was started, and upon the ring being removed, it was found that a small amount of grit had been loosened by the action of heat and cylinder oil, thus causing the cylinder to be badly cut and scored.



TWO DESIGNS OF BULL RINGS

Had the ring been constructed as shown at *B*, all particles of sand or grit could have been scraped out easily and considerable time and expense saved. The ring would have been but little heavier, and it would have been easier to mold. **Charles W. Oakley.**

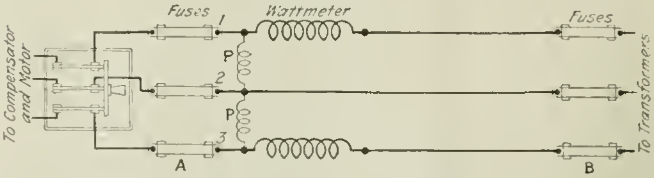
Passaic, N. J.

Lamp Test Indicated a Ground

Each of the three conductors of a three-phase three-wire service involves two of the phases of the circuit, and an open-circuit in any one of the three wires will interrupt two of the phases. With only one phase active, there will be no phase rotation, therefore a three-phase motor will be unable to start if connected to the circuit.

The figure shows the line circuit for a 220-volt three-phase motor, which was complained of because it could not be started. The two sets of fuses shown were active on both positions of the starting compensator. A test with a 220-volt lamp showed that the middle fuse located at the transformers about 200 ft. away from the motor, was blown. The test lamp would light when applied across lines 1 and 3, but would only glow dimly when applied to 1 and 2 or to 2 and 3. The motor trouble was a plain case of single-phase operation which was remedied by replacing the blown fuse. The fuses at *A* and *B* were all of 60-amp. capacity and a fuse was as liable to blow at *B*, which was inaccessible, as at *A*, which was immediately above the motor. In order to insure that the next fuse would blow in a convenient place, 45-amp. fuses were substituted for the 60-amp. fuses at *A*.

As pointed out in the foregoing, when testing for voltage the lamp showed an appreciable glow when held across conductors 1 and 2 or 2 and 3; this suggested the existence of a leak to ground. The operator spent some time in trying to locate a ground, when he happened to think of the watt-hour meter, the connections of the potential coils of which are indicated at *P*. On disconnecting the potential coils, all wires tested clear.



THREE-PHASE-MOTOR LINE CIRCUIT

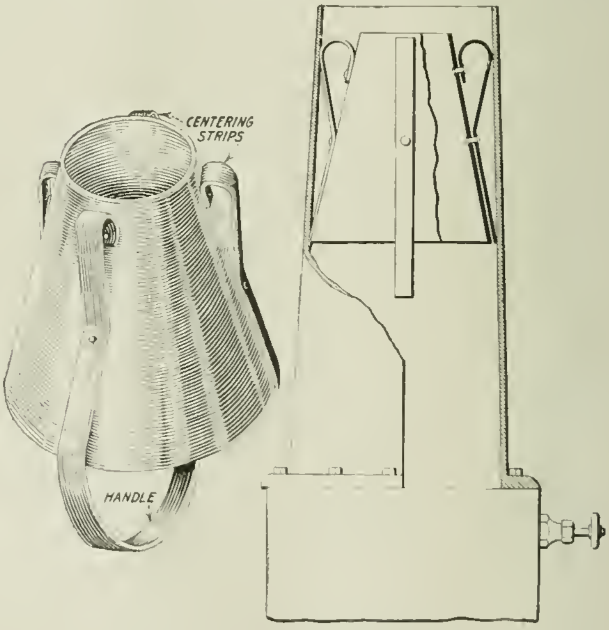
Reducer for Gas Burners

In a boiler plant using natural gas as fuel it sometimes becomes necessary to turn the gas very low, often resulting in the gas firing back into the burners, or to run with one burner nearly full on, which is undesirable and likely to deposit sediment in a form that causes blistering or bagging. To overcome this I hit upon the idea of reducing the nozzle of the burners from 5 to 3 in. in the manner shown in the illustration.

No. 20 gage galvanized iron was used to form a funnel-shaped reducer to fit into the regular burner with three or four strips ¾ in. wide riveted on in the manner shown, to center the small end. A handle is also provided to insert and remove the reducer. By using these reducers, it is possible to reduce the gas so that three burners can be kept going in place of one, giving a better distribution of heat and a more economical mixture than could be obtained with the large burner burning low without the reducer.



NOZZLE OF GAS BURNER REDUCED

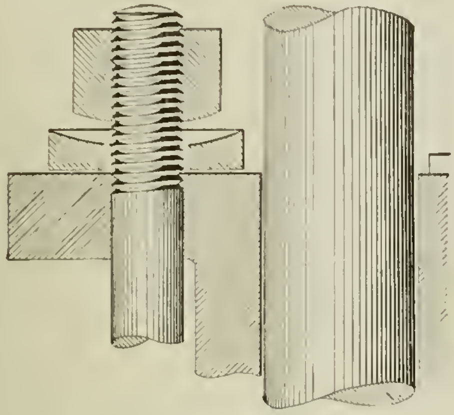
Relieving Side Strain on Studs

To keep studs or gland bolts from breaking from side strain, I make a washer a loose fit over the bolt and flat on one side but concave on the other. The nut is then made convex to fit the hollow side of the washer, forming a ball joint. The washer will slide one way or the other and adjust itself to the pull so that the stud does not bend repeatedly and finally break. The illustration shows the shape of the nut and special washer as described. R. A. DAVIDSON.



NUT AND WASHER FORM A BALL AND SOCKET JOINT

Ammonia-Compressor Diagrams for Discussion

The indicator diagrams shown in Figs. 1 to 4 are from a 10-ton Wolf-Linde ammonia compressor, 9½ x 15 in., running at 80 r.p.m. normally, and motor-driven. I shall be pleased to have readers of *Power* discuss the diagrams. J. C. HARRISON.

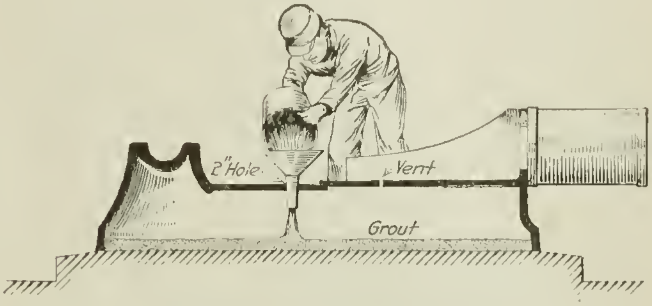
FIGS. 1 TO 4. AMMONIA-COMPRESSOR DIAGRAMS FOR DISCUSSION

Grouting in an Engine Bedplate

Sometimes the hollow bedplates of machinery will move slightly on the foundation if insufficiently grouted, and cases of this kind are aggravating and difficult to correct. The usual cause is that the grout was not forced into all the interstices under the heavy casting, consequently there is not sufficient bearing surface. One way to correct such a defect is to drill a hole, about two inches diameter, in the top of the bed and another for an air vent and pour in grout enough to fill the inside of the bedplate to a depth of several inches. This will usually stop any motion of the frame on the foundation. D. R. SHEARER.



GROUT POURED INSIDE OF HOLLOW BEDPLATE

Johnson City, Tenn.

Insufficient Protection Around Flywheel

In a station that I visited recently, there was an immense flywheel in motion just at the end of a runway, about six inches from the end of the walk, the floor being about level with the hub of the wheel. There was a single wooden handrail around it, nailed to the top of posts, leaving the whole space below unguarded. The engineer in charge said that one man had slipped into this wheel, but no better protection had been placed there to prevent anyone else from meeting with a similar accident. Failure to improve conditions after one such accident seems like gross negligence.

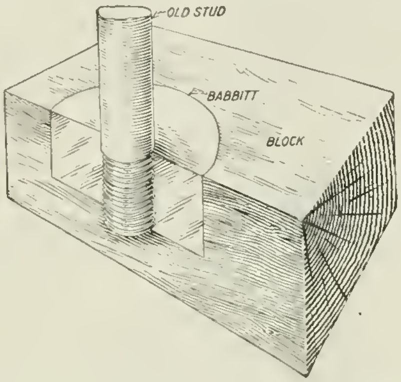
Babbitt Templet for Thread Size

Following is a shop kink that may be of interest to readers of *Power*. I recently bought a set of new ¾-in. studs for the water valves of a duplex pump, but the threads had not been cut deep enough to screw into the seats properly and as they were special threads it was necessary to "chase" them in a lathe. The pump could not be spared from service long, and the question arose as to how we would know when they were "chased" to the proper depth. This was solved by boring a 1½-in. hole in a wood block to the depth of the threaded portion of the studs. The threaded portion of an old stud was then set in the hole in the block and melted babbitt poured around it. When it had cooled, the stud was backed out, leaving a templet of the thread in the metal, as shown in the illustration. The new threads, cut to fit this templet, fit perfectly in the valve seats.



TEMPLET MADE BY POURING BABBITT AROUND OLD STUD

Induction Motor Heated

When a three-phase induction motor of standard design has trouble that causes abnormal heating even when the motor apparently is operating without any connected load, the source of disturbance very likely will be unbalanced voltage, which may be determined by connecting a voltmeter across the different phases, or an ammeter is successively connected into the different supply wires. If under such conditions the readings prove to be balanced, the motor either is not what the nameplate calls for or the seat of trouble is elsewhere.

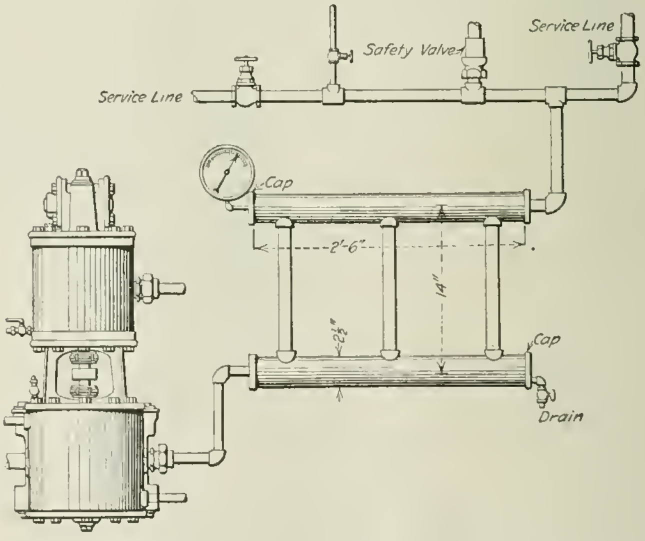
The operator of a motor-generator set which consisted of a three-phase induction motor coupled to a shunt-wound direct-current generator, complained that the motor got so hot as to smoke even when the generator was carrying no load. An inspector was sent to investigate and by means of an ammeter and a voltmeter determined that there was nothing the matter with the motor as far as the meter readings would indicate.

During the taking of the no-load readings of the motor, the generator was entirely disconnected electrically and therefore could not even excite its field poles. In order to determine whether the proposed field connections were correct for the given direction of rotation, the inspector held the free field terminal to one of the armature terminals. Almost immediately the character of the noise that was emitted by the set changed, and it was evident from the drop in the speed that the motor was heavily overloaded. Shutting down the set and feeling of the generator's armature disclosed that it was very hot. Inspection revealed that the generator-bearing lining on the commutator end was melted and had been for some time. As long as the generator was not excited, the bolted coupling was able to hold the armature free from the polepieces; on exciting the field coils, however, the armature was pulled against the polepieces, thereby creating a most efficient brake, which overloaded the motor. E. C. **Parham.**

Brooklyn, N. Y.

Receiver Eliminates Moisture

The illustration shows a home-made air receiver, connected to a Westinghouse air compressor, which has been found efficient in separating the moisture from the air. No moisture is perceptible on the hand held within four inches of the end of the service pipe with the valve wide open. The headers were originally used on an ammonia pipe system and are made of 2½-in. pipe with lugs or saddles for 1¼ pipe attached. The size is of no great importance except that the air velocity through the connecting pipes should be low. The construction may be easily understood by referring to the illustration. The air from this compressor is used in four "dry" sprinkler systems and one "wet" system and also for "blowing out" the generators, so it is highly desirable that the air be as free from moisture as possible. The result has been so satisfactory that I want to pass the suggestion along.



AIR RECEIVER MADE FROM OLD AMMONIA PIPING

Quincy, Ill. C. L. **Boyle.**

Have you been appointed supervisor of illumination in your mill or building? Maybe you have not advised the boss that one is necessary, though your observation of the charts and meters tell you there is.

Inquiries of General Interest

Working Pressures for Pipe, Valves and Fittings—What is the safe working steam pressure for standard and extra-heavy pipe, valves and fittings? S. E.

"Standard" pipe, valves and fittings are assumed to be suitable for working steam pressures not in excess of 125 lb. per sq.in. and "extra heavy" pipe, valves and fittings are assumed to be suitable for working steam pressures to 250 lb. per square inch.

Fluctuation of Electric Pump-Pressure Regulator—The operation of an electrically driven pump is very irregular on account of hammering of the pump that causes continual fluctuations of the pressure regulator and making and breaking of the electric circuit. How can this be remedied? E. E. F.

The pump discharge should be provided with an air chamber for equalizing the discharge pressure, and the pressure connection to the regulator should be throttled so as to dampen the pulsations.

Beveling of Safety-Valve Seat at Angle of 45 Deg.—Why is a safety valve beveled at an angle of 45 deg.? C. V. S.

Valve seats are straight-beveled or rounded, to afford better facilities for grinding the valve to its seat. Beveling at approximately 45 deg. gives a good form for a beveled seat and that angle probably is easier than any other for manufacturers to obtain and duplicate. The adoption of 45 deg. as a standard is purely conventional. Any other bevel might be taken as a standard for safety valves, provided the rated discharge capacities of different diameters are based upon a specified lift and angle of beveling.

Saving by Increase of Feed-Water Temperature—For generation of the same amount of steam at 100 lb. per sq.in. boiler pressure, what per cent. of coal should be saved by increasing the temperature of the boiler-feed water from 50 deg. F. to 150 deg. F.? F. B.

Each pound of the steam generated at 100 lb. boiler pressure, or 115 lb. per sq.in. absolute, would contain 1188.8 B.t.u. above 32 deg. F., and conversion of each pound of the feed water from 50 deg. F. into steam at the pressure would require 1188.8 + 32 — 50 = 1170.8 B.t.u. With the feed water at 150 deg. F. each pound of the feed water would contain 100 B.t.u. more than when the temperature of feed water is 50 deg. F. Hence for each pound of the feed water at 150 deg. F. generated into steam, there would be a saving of 100 ÷ 1170.8 = 0.0853, or about 8½ per cent.

Objections to High Initial Pressure with Light Load—What are the objections to operating a noncondensing Corliss engine with high initial pressure for carrying a light load with very short cutoff? W. H. C.

For given variations of load the required range of governor action will be less and there will be greater hunting action of the governor, accompanied by less regularity of speed, and for derangement of the valve gear the engine is more likely to race from a high than from a low initial pressure with a light load. There also will be less uniformity of rotation during one revolution. Unless compression is adapted to the conditions, the percentage of clearance waste will be higher, because there will be the same volume of clearance space steam of greater density. When the initial pressure is high, with cutoff so short that expansion occurs down to or below atmospheric pressure, the rush of air into the cylinder when the exhaust opens results in cylinder cooling that is detrimental to economy and usually is accompanied by clattering of the exhaust valves and injury to the exhaust valves and their seats.

Heat Value of Fuel and Theoretical Evaporation—What is meant by the heat value of a fuel and the theoretical evaporation per pound of the fuel? J. H. H.

The heat value of the fuel is the number of British thermal units that would be realized by theoretically complete combustion of a pound of the fuel, a British thermal unit (usually designated by the abbreviation B.t.u.) being $^1/_{180}$ of the quantity of heat required to raise 1 lb. of water from 32 deg. F. to 212 deg. F., though in most practical computations 1 B.t.u. is roughly taken as equal to the quantity of heat required to raise 1 lb. of water 1 deg. F. When no other conditions are stated, evaporation is understood to refer to evaporation from water at 212 deg. F. and at atmospheric pressure, commonly expressed as "evaporation from and at 212 deg. F." Evaporation of 1 lb. of water from and at 212 deg. F. requires the latent heat of evaporation, or 970.4 B.t.u. If a fuel has a heat value of 14,000 B.t.u. per pound, the theoretical evaporation from and at 212 deg. F. would be 14,000 ÷ 970.4 = 14.42 lb. of water per pound of the fuel. On account of losses of the fuel through the grates, imperfect combustion, losses of heat by radiation and heat wasted in the chimney gases, the actual evaporation, or evaporative efficiency of boilers, is only 50 to 75 per cent. of the theoretical, depending on the type of boiler and other conditions.

Water Delivered by 4-In. Pipe—What number of gallons per hour will pass through a 4-in. pipe about 1 mile long with the pressure at the entrance 90 lb. per sq.in. and with discharge taking place against a pressure of 45 lb. per sq.in.; and what would be the velocity in feet per minute? D. T.

The velocity of flow will depend on the roughness of the interior pipe surface from construction, corrosion and incrustation. Darcy's formula for loss of head in new cast-iron pipe reduced to English measures is

$$h = \left(0.01989 + \frac{0.001666}{d}\right)\frac{l}{d} \times \frac{v^2}{2g}$$

in which

h = Loss of head due to friction, in feet;
d = Internal diameter of pipe in feet;
v = Velocity per second in feet;
l = Length of pipe in feet;
$2g$ = 64.32.

In the problem, the loss of head due to friction is 90 — 45 = 45 lb., or 45 × 2.309 = about 104 ft.; $d = \frac{1}{3}$ ft. and l = 5280 ft. The velocity is to be found by substituting the given values of d and l, and, by assuming different velocities, determining the value for v which will most nearly satisfy the equation. In the example the nearest velocity will be about 4.09 ft. per sec. or 245.4 ft. per min. As the cross-sectional area of 4-in. pipe is 12.566 sq.in., the flow per hour would be $\frac{4 \times 4 \times 0.7854 \times 245.4 \times 12 \times 60}{231} =$ 9611 gal. for new 4-in. cast-iron pipe.

For pipes that have been in use under average conditions h in the formula is to be multiplied by about 1.25 for 5 years' service, by about 1.5 for 10 years' service and by about 1.75 for 25 years' service.

Boiler-Room Efficiencies*

By GEORGE F. WEATON†

Labor conditions make high efficiency more difficult than ordinarily and increase very considerably the operating costs. Suggested equipment for a 1000-hp. plant. Judging combustion by observation of flame through violet glass. Results in the boiler room of a typical manufacturing plant. Discussion on the paper.

So much does design influence the efficiency possible in the boiler plant that it is desirable to review what is wanted as to equipment. Though a few years ago a plant could be operated at the then standard of economy with simple equipment, this is no longer true. Labor was obtainable at such a wage that the installation of much mechanical apparatus was questionable in plants of fairly large proportions; plants of 1000 hp. and over were seldom provided stokers, coal- and ash-conveying machinery, fuel economizers, mechanical draft, etc. However, the change in labor has been so radical, coupled with its scarcity and high wage, and the difficulties of maintaining discipline and organization in a plant of moderate capacity so extreme, that it is safe to say that no plant of, say, 1000 hp., should be without boiler units of as large a unit capacity as can be installed after considering lay-offs for cleaning, repairs, etc. I should suggest three 350-hp. boilers, fuel economizers, underfeed stokers, coal and ash conveyors and overhead coal storage. Two men could economically operate such a plant; there is boiler capacity sufficient to lay off a boiler for repairs and cleaning, stoker and draft apparatus are sufficient to operate economically above rating and carry the load on the remaining two boilers. The returns on such an investment, although not so much as on a larger plant, will be greater than for a smaller investment for a more simple plant.

Oil Versus Coal as a Fuel

Oil as a fuel at the present here in New England appears as a more or less vigorous competitor of coal. In this section its use will be limited to a few plants. Oil presents many qualities that make it an ideal fuel, such as large overload capacities, cleanliness, no ashes or other bulky material to handle; the handling apparatus is not subject to such rapid deterioration as is coal-handling apparatus; ease of regulating the air supply to the exact amount required for most efficient combustion and small labor requirements.

It appears that oil might be seriously considered in plants of moderate capacity; but the considerations must extend much farther than a tidewater storage for a large plant. Every precaution must be taken against the possibility of cutting off the fuel supply. That a large oil company has storage supply normally of thousands of gallons at tidewater is not sufficient guarantee of unbroken supply to a large consumer. Oil-field labor is mostly turbulent, although not so much might be published about their doings as the coal miners' troubles, oil being of lesser importance than coal as a fuel. Transport by sea is subject to Government requirements, and transport by rail may make oil prohibitive in price. Oil as a marine fuel is used in increasing quantities, and it appears that oil will be the marine fuel of the near future. It will not supplant coal either in quantity or in price as a land fuel unless new and extraordinary fields are discovered. Coal must receive the most consideration by engineers.

Economy in the use of fuel is now being preached as never before. While the sermon is highly commendable, economy should be practiced at all times, not as a war measure only; if it can be done in war time, it can be done during peace. If this war will cause the more general practice of economy, not only in fuel but also in many of our vital resources, the ill wind will blow some good.

Of first importance in the burning of coal is control of combustion; second, the condition of the boiler in respect to cleanliness and repair; third, the condition of the setting in relation to the loss by radiation and the dilution of the gases and cooling of heating surfaces by air leakage.

First, it must be understood that the combustion of fuel is distinctively a chemical process consisting of the rapid oxidation of whatever is combustible, before combustion can take place. The combustible must be brought up to a temperature where chemical union with oxygen will take place; these temperatures vary for different fuels.

Second, there must be available a sufficient and not excessive supply of oxygen heated to the proper temperature, or good results will not be had. Each pound of carbon by theory requires 2⅔ lb. of oxygen, but in practice it is usually calculated that an excess of 40 per cent. is required. In late plants of good design this excess requirement has been made as low as 20 per cent., and the boiler efficiency obtained is 82 per cent.

Third, the gases from the fuel and oxygen must be brought into intimate physical contact.

The construction of the furnace must be such that these conditions are fulfilled and combustion aided or skill cannot get good results.

The Control of Combustion

In the ideal plant the control of combustion would be as automatic as it would be possible to make it. This requires stokers where the air supply would be controlled by the rate of coal feed, which is in turn controlled by the demand for steam. The coal would be uniform in size and in moisture content. This requires coal crushers and overhead sheltered storage of a supply sufficient for a number of days. The draft should be so regulated that there would be a practically balanced pressure in the setting and out to minimize air leakage in through the setting and escape of gases from the setting. Next, the fireman or man in control of the fires should be among the most intelligent of the plant, and should receive the highest wage of anyone in the plant except the man in charge. He could and would save many times his wage in the average large plant. The great majority of firemen are totally ignorant of the principles of combustion.

Provided we have a well-designed furnace, we can check results by at least four ways; three of these may be termed indicating and one recording. Of the three indicative methods, that of gas analysis is the simplest and the most reliable. Every plant should have at least an Orsat or similar hand apparatus for the determination of the CO_2, CO and O_2 content of the gases. While samples of gas are being drawn, the temperature of the gases should be taken. Carbon-dioxide recorders are desirable but not necessary, as conditions can be fixed and followed from time to time by the hand apparatus, which has the advantage over the CO_2 recorder inasmuch as its gives the CO_2, CO and O_2, which the recorder does not do.

Another method is by judging the colors of the products of combustion in the furnace. Men who have had experience together with the study of the principles of combustion can judge a fire very accurately. For this purpose peepholes are built into the furnace walls and dense violet-blue glasses are used, as it is impossible to observe the color changes with the naked eye. The natural color of the gases when combustion is perfect is a bright red or white-red; it is a haze. After fuel has been thrown on, the gases rising are streaked with a dun-colored opaque gas, indicating that all the combustible gases have not been ignited. This gas, upon entering the combustion chamber, should become transparent as before. These changes cannot

---

*A paper before the Providence (R. I.) Engineering Society, Dec. 14, 1917.

†Chief engineer, The J. & P. Coats Co., Providence, R. I.

be observed with the naked eye unless the furnace temperature is too low to give efficient thermal results.

When using glasses, the color changes can be observed closely. Imperfect combustion is indicated by dark streaks obscuring the opposite sides of the furnace; perfect combustion by a clear lavender-gray color. Red and yellow flames, which interfere with the naked-eye vision, are cut out by the glass and these rays, when passing adjacent cool surfaces, possess little light that is capable of passing through blue glass. Therefore, perfect combustion takes place at a temperature that will produce light powerful enough to penetrate blue glass, indicating a high actinic power and intense chemical action. The dun-colored gases rising from the fuel bed should, upon entering the zone of perfect combustion, disappear, leaving the clear lavender-gray color.

The third method is by means of the temperature of the furnace. With a room temperature of 60 deg. F., burning one pound of carbon to complete CO_2 will produce a temperature of 5002 deg. F. This in practice is impossible. For good practical results the furnace temperature is from 2800 to 3000 deg. Fahrenheit.

While these checks are indispensable in obtaining good results, the most reliable check is the actual results secured. These can be obtained only by means of metering the feed water fed to the boiler and making allowance for all water blown out of the boiler or used for other purposes if drawn between the meter and the boiler, by accurately weighing the fuel and by periodic temperature readings of the steam, feed water, flue gas, etc., also steam-pressure observations. No plant should be without these valuable adjuncts that give such information, and any plant not so equipped, unless it be very small, will waste enough in a surprisingly short time to pay for the outfit required. Unless results are checked daily and conditions kept at their best by the lessons taught instruments are useless.

Boilers should be cleaned periodically, internally and externally. Cleaning should not be put off until someone thinks it is needed, as the judgment of man is too erratic to be efficient. There have been developed a few good soot blowers, and their installation is desirable. I have yet to find the man that will blow tubes with the steam hose and do it properly unless the ax is held by a thread over his head.

Keep the setting air-tight and well insulated. Brick settings are never tight, and painting will not make them tight, as the paint dries out so rapidly that the expansion and contraction cause it to develop miniature cracks, which, upon close examination, will be found to be caused by like cracks in the setting. If the hand is carefully passed over the setting, the temperature changes felt will show air leakage in a setting thought to be tight. There are some good elastic cements with which settings may be plastered and which do not harden and will maintain a tight setting. Doors set in masonry will be found probably the worst offenders if mortar is depended upon for the joint. Painters' putty applied about the joint and then painted will keep them tight for a long time. These remarks apply likewise to the flues, economizers and chimney—air leaks anywhere cost money.

THE EFFICIENCY OF LABOR HAS FALLEN

Three years ago it was possible with study and patience to weld labor into an efficient organization. Today it is rather the other way—labor draws the heat. The "efficiency" of boiler-house labor has in three years fallen easily 30 per cent. Three years ago our boiler plant had a manual efficiency, based on time studies, of 60 per cent., and on some operations as high as 70 per cent. All have fallen some, the most decided slump being on the part of the firemen. Coal handlers give the most trouble as to the steadiness of the workers. In the last few months it has been irksome to keep them on the job, and the prospects of holding the efficiency are poor indeed notwithstanding that over 32c. per hour is paid. When it comes to a choice between fuel efficiency and labor efficiency, the labor efficiency must be sacrificed to keep down operating costs.

The following describes the operation of passing coal in the plant I have in mind. Coal is dumped alongside the boiler house on a level with the floor. From here it must be wheeled from 50 to 150 ft., then lifted 8 ft. to the stoker hoppers. Two-wheeled balanced barrows are used with a nominal capacity of 500 lb.; the average load will be about 530 lb. We have had men who by skillful loading would carry 700 lb. to the trip. Loading is done with a No. 5 scoop. If the coal is lumpy, the passer must break it to lumps not larger than his fist to avoid clogging the stoker hopper.

The operator handled on an average for the day 679.32 lb. per trip. This is higher than the average. The distance wheeled was more than 20 ft. over granite-block paving, 15 ft. over brick, up on an elevator and then on 80 ft. of steel plate, from which the coal was dumped into the stoker hopper. The time-study efficiency was 70.26 per cent.; fifty-nine trips were made, the average time per trip including all operations being 7.17 min.; the total coal handled was 40,080 lb. At present five men handle approximately 190,000 lb. in 24 hours, an average of 38,000 lb. each, which gives a cost for handling of about 21.5c. per gross ton. I do not believe that this figure can be reduced under the conditions.

Our operation for the boiler plant is as follows: One boiler is operated Sundays, five additional boilers are fired anew each Sunday night, so six boilers are operated days during the week and four are operated at night excepting Saturday and Sunday nights. The fires in the five boilers are allowed to burn out Saturday afternoon.

For general plant-operating economy the results of the week ending Nov. 10 may be taken as typical:

Total coal consumed (includes coal used for banking and starting), lb.	1,113,670
Total net evaporation, lb	10,435,060
Live steam to mill heating, per cent. 8.45, lb	883,150
Live steam to mill processing, per cent 22.9,	2,389,800
Live steam to mill power generation, per cent. 68.65, lb	7,162,110
Actual net evaporation per pound of coal, lb	9.37
Equivalent evaportation from and at 212 deg. F. per pound combustible, lb	13.1
Kilowatt-hours generated	386,730
Kilowatt-hours, output	354,600
Power coal per kw.-hr. generated, lb	1.98
Total coal per kw.-hr. generated, lb	2.89

The boiler-house percentage charges for the year ending June 30, 1915, with a boiler load factor of 33.45 per cent., were as follows:

Fixed charges	19.45
Management	3.70
Water, lubricants, tools and miscellaneous	0.35
Labor	7.17
Carting ashes and refuse	1.14
Fuel	62.9
Supplies	0.52
Repairs	4.77
Total cost of 1,000 boiler horsepower-hours, dollars	10.58
Cost of 1,000 lb. of steam from and at 212 deg. F., cents	30.67

Eliminating the item of fixed charges, fuel cost was 78.25 per cent of the operating expense.

Actual net evaporation per pound of coal, lb	9.215
Equivalent evaporation from and at 212 deg. F. per lb. combustible, (includes the economizers), lb	12.45
Kilowatt hour output	10,106,750
Coal per kw.-hr., lb	2.165

The cost of 1,000 lb. of steam at 212 deg. F., including all charges is approximately 49c. at present.

DISCUSSION

H. A. WILCOX: I believe that this lack of equipment which Mr. Weaton mentions is due to lack of education on the part of owners and managers as to what could be done in the way of boiler-plant economy. It may safely be stated that managers were and are today unwilling to spend a cent on the nonproducing part of their plants and the boiler plant has, until late years, been considered a necessary evil rather than the heart of the plant. This feeling has gradually undergone a change, due to the entrance of highly trained efficiency engineers into the field and to the retaining of expert engineers by the manufacturers of boiler-plant accessories. These men are capable of bringing clearly into the understanding of managers the benefits to be derived from the installation of their equipment and therefore the use of stokers, coal conveyors, etc., has grown apace. Mr. Weaton ascribes this to the present high wages paid for labor, but I cannot agree entirely with him, as the price of the finished product has advanced correspondingly, leaving as large a margin of profit as in previous years.

It has been suggested that for a plant of 1000 hp. three 350-hp. boilers, economizers, underfeed stokers, etc., should be used. I am inclined to think that this statement is rather broad. The nature of the industry to be served must be considered, such as: (1) Is 24 hours of operation at 1000 hp. required every day in the week? (2) Will there be exhaust steam available for heating the feed water and can exhaust steam be used in process work? (3) Do the summer and winter loads vary greatly? (4) What provision must be made for future expansion? (5) Is the location of the plant such that it will be able to receive fuel deliveries by rail or by water? (6) Finally, commercial efficiency, based upon the foregoing considerations, will determine the equipment desirable for the plant. By commercial efficiency is meant thermal efficiency properly modified by monetary values. In other words, owing to plant location, nature of the product or like considerations, a plant may be equipped to burn a high grade of bituminous coal of 14,500 B.t.u. and costing $4 per short ton, at 75 per cent. thermal efficiency. This should produce 1000 lb. of steam at a fuel cost of 17.85c. If there is in the same market a poorer grade of coal having 12,000 B.t.u. per lb. and costing $2 per short ton, this same plant should operate at only 68 per cent. thermal efficiency, but would develop 1000 lb. of steam for 11.9c., which shows a fuel-cost saving of about 33⅓ per cent. Considering commercial efficiency, it would therefore seem that a decision for underfeed stokers is somewhat premature before it has been determined whether bituminous or anthracite coal will be used, because underfeed stokers will burn bituminous coal at very high efficiency, while to obtain 68 per cent. efficiency with clear anthracite, such as buckwheat, culm and barley, chain or traveling grates are a necessity.

Assume that these items have all been considered and that the equipment, as outlined previously, has been found most desirable. There is some doubt as to whether two men could operate such a plant economically. I believe that one man would be needed to run the stokers, tend the water, etc.; one man to operate and look after the maintenance of the coal- and ash-handling machinery; and one man for cleaning economizers, cleaning and repairing each boiler as it is laid off, and doing general odd jobs which would naturally develop in a plant of this size. In a plant of several thousand horsepower there is no doubt but that an allowance of two men per 1000 hp. would be ample. In a plant equipped with stokers, however, I think that a plant of only 1000 hp. would require the force enumerated in addition to the chief engineer. I also believe that the installation of stokers, if of the proper type, will materially improve plant efficiency and cut down the payroll as compared with hand-firing.

Use of Oil To Increase

I heartily indorse the opinion that oil appears to be a vigorous competitor of coal, but disagree with the statement that its use in this section will be limited to a very few plants. A few installations in this vicinity named from a long list will serve to illustrate. These plants are not especially selected, but as you will note, vary considerably in size: The Shepard Co., the Boston Store, the Atlantic Mills, Providence; the Lorraine Manufacturing Co., Slater Manufacturing Co., D. Goff & Sons, the Memorial Hospital, Pawtucket; the River Spinning Co., the Nourse Mill, the Social Mill, Woonsocket; and the largest New England mills of the American Woolen Co. are either already equipped to use oil fuel or have contracted for its immediate installation. The "Meypet" list comprised of their New England customers contains the names of 47 plants. I am informed that the oil fields which supply the plants named are located in Mexico and are worked by native laborers who are paid much higher wages than they would receive at their ordinary occupations. It is probably due to these facts that these oil fields have remained entirely unmolested during the recent upheavals in that country. A glance at any reliable newspaper is sufficient evidence as to labor conditions in the coal regions. As to transportation, all are aware of the rapid movement of all kinds of rail shipments. Present activity in shipbuilding indicates that transportation by water, which is the only economical method of supplying fuel oil to the northern and eastern sections of this country, should be facilitated rather than retarded. If this reasoning is correct, we can only assume that shipping facilities from all these fields will grow in direct proportion to their development. So it is likely that after the present emergency oil will be an even greater competitor of coal. I therefore believe that the use of oil as a fuel will largely increase during the next few years in this section as well as in others.

A source of considerable waste, which has not been mentioned, is the loss of combustible through the grates and in cleaning fires. A glance at the ash pile or an analysis of the ash of many plants now in operation will clearly reveal this loss.

Having determined what factors are of prime importance toward attaining maximum fuel economy, the question arises as to how we shall know when we have reached and are maintaing the highest possible standard of economy. The answer is simple: Periodic, frequent layoffs and examinations externally and internally will demonstrate the state of cleanliness and repair of boilers, stokers, economizers, etc., and a frequent analysis of the ash will determine the loss of combustible through the grate. This examination is such an important factor in the maintenance of fuel economy that it should not be beneath the dignity of the chief engineer to make sure that it is properly carried out even if it becomes necessary for him to make a personal investigation.

Importance of Gas Analyses

I am inclined to think that inspection of the fire through violet glasses, as outlined by Mr. Weaton, is not a very reliable indication, by reason of the liability to error in human judgment. I do not wish to be understood that his examination is without any value, as the general condition of the fuel bed with respect to holes, clinker, etc., may be absolutely determined in this way.

Fortunately we have an exact means of controlling combustion, called by Mr. Weaton "Indicating." I believe that a CO_2 recorder and an Orsat are both requisite. There are too many variables entering into combustion to permit of fixing conditions which can be followed for any length of time. Therefore, a recorder or a sampling tank capable of drawing a sample of flue gas over a long period of time is essential; it gives the average operation for any period of time, and any deviation from good practice is at once noticeable. Of course, in the installation of automatic apparatus for the analysis of flue gas it is vitally important that it be so located and arranged that the record of conditions at any one time is made within the least possible interval of time from the occurrence of the conditions. This is to simplify the determination of the causes of any change that may occur. An Orsat should be used from time to time as a check upon the recorder and to determine the location of trouble arising from a deficiency or excess of air, etc. I believe, with Mr. Weaton, that recording instruments giving flue temperatures, drafts, amount of feed water, weight of coal fire, etc., are indispensable aids to fuel economy.

Recommends Heat Balance

These instruments are all valueless unless their indications are intelligently interpreted. An exact interpretation is possible by the use of the heat balance. By the use of the recording instruments mentioned, a heat balance, covering any period of time, may be made and the exact extent and location of any preventable losses readily determined. Steps may then be taken to minimize these losses, a new heat balance made and the result of changes or the amount of improvement will be seen.

The human factor is at least equal to design in importance. By human factor I mean not only the fireman, but the management also. Given a plant such as described in Mr. Weaton's paper, I consider that the following additional conditions must exist to develop the highest plant efficiency attainable:

First, the management must be of a type which will take an interest in maintaining the highest boiler efficiency by an intelligent scrutiny of the daily records and a systematic method of keeping after the man on the job; second, the man on the job or chief engineer must be an intelligent and highly paid man—a man who has familiarized himself with the theory and practice of combustion and its control.

May I suggest that a paper by a member of the society on the general methods of investigating and overcoming preventable wastes in existing boiler plants would be valuable?

Following Mr. Wilcox, F. N. Connet, chief engineer, Builders Iron Foundry Co., Providence, described the installation and operation of the venturi meter. He emphasized the need of freedom from vibration and the desirability of nonpulsating flow for accurate measurement by the meter. This, he said, was given by the centrifugal feed pump. Mr. Connet also mentioned the good effects of feeding water to the boilers so as to anticipate coming loads. He showed several charts, both from the venturi meter (quantity fed) and from recording thermometers recording feed temperatures, to reveal how the average feed temperature was much more constant when steam demands were anticipated by raising the water level during periods of light steam demands and closing off the feed-control valve during heavy demands. It was interesting, he mentioned, that for years design of feed-water regulators had been to give continuous feed, while now design was tending to give periodic feed, with the aim of anticipating demands.

Henry Ballou, of Jenks & Ballou, consulting engineers, Providence, agreed that the many instruments and apparatus mentioned by Mr. Weaton and Mr. Wilcox were desirable, but said it was his observation that 98 out of every 100 average plants did not have them. He spoke of the Manning boiler as one in which air leaks were nil on account of the enclosed firebox. Mr. Ballou said that the use of oil was influenced more by the freedom from labor troubles consequent to its use than by questions of economical combustion. He spoke of the oil-burning plant of the Tamarack Mills, Pawtucket, R. I., which recently went into service and which was designed exclusively for oil. [See *Power*, Mar. 27, 1917, for brief description of this plant. A full description is now in preparation for an early issue of *Power*.]

Charles H. Bromley, associate editor of *Power*, presented many data on the coal and freight (rail and marine) situation, and read a communication from the Bureau of Mines calling attention to current coal containing from 50 to 200 per cent. more ash than in normal times. He dwelt on the futility of getting large returns by attempting to educate the fireman, something that had for years been tried and proved a failure. General adoption of approved furnace design and the employment of highly competent supervision for the boiler-room force were the requirements that held forth the great and only promise in fuel conservation on a large scale.

W. B. Lewis presided. The next paper in the Power Section was "From the Coal Pile to the Lamp," by Jesse E. Gray, chief engineer, Narragansett Electric Light and Power Co., Providence, read Dec. 21.

Deterioration in Heating Value of Coal During Storage

There is a marked agreement in the conclusions reached by the United States Bureau of Mines, as published in Bulletin 136, and the Engineering Experiment Station of the University of Illinois, Bulletin 97, in regard to the effect of storage upon the heating value of coal. The tests show that the deterioration of coal in heating value during storage has commonly been overestimated. Except for the subbituminous Wyoming coal, no loss was observed in outdoor weathering greater than 1.2 per cent. in the first year, or 2.1 per cent. in two years, but the Wyoming coal suffered somewhat more loss—2 to 3 per cent. in the first year and as much as 5.5 per cent. in three years.

In general the conclusion to be drawn from the tests by the Bureau of Mines on New River coal is that under severe conditions of outdoor exposure to the weather it deteriorates in heating value approximately 1 per cent. in the first year, 2 per cent. in the first two years, and not over 3 per cent. in five years. Storage under water prevents practically all deterioration during one year, and no more than 0.5 per cent. has been found in any test for two years or less. Salt water possesses no advantage over fresh water in preventing deterioration. Intermittent exposure and partial drying of the submerged coal probably causes deterioration in some degree, although very small, therefore submergence storage of New River coal is not to be recommended for the sake of preventing deterioration in heat value—its advantage lies only in insuring against spontaneous combustion.

The amount of deterioration of coal from the Pittsburgh beds in one year's open-air storage at the University of Michigan was practically negligible, even in the upper six inches of the exposed coal. During the second, third, fourth and fifth years the deterioration proceeded very slowly and did not reach an amount greater than 1.1 per cent. in five years. The submerged portions may be said to have suffered practically no loss measurable by the degree of accuracy used.

Tests of Pocahontas coal at Panama show that during one year's outdoor exposure it deteriorated very slightly (less than 0.4 per cent.) in heating value, and that the deterioration took place entirely during the first six months (June 15 to Dec. 15). There was a further deterioration of 0.4 per cent. during the second year.

Exposure Increases Weight of Coal

Laboratory experiments have shown that coal ordinarily increases slightly in weight on exposure to the air. It is possible, therefore, that the net losses in heating value may be slightly less than reported, since the actual weight of fuel substance present may be somewhat greater, although its heat value per pound is less than when the coal was stored.

In the storage of Sheridan (Wyo.) coal for more than three months, covering the bins is not as advantageous as the use of air-tight bottoms and sides (of concrete, for example) and the accumulation of a protecting layer of fine slack on the surface. The deterioration of Sheridan coal in heat value can probably in this manner be kept below 3 per cent. in one year, and will probably not increase to more than 4 per cent. in two or three years if the coal remains undisturbed. Physical deterioration (slacking) is also largely prevented in the under portions by the formation of a closely packed layer of slack, at least 12 inches thick on the surface.

Although no indications of spontaneous heating were noted in the tests described, it is found in practice to be dangerous, on account of heating, to store Sheridan coal in piles greater than about ten feet in depth or width. In large masses of coal radiation of spontaneously developed heat is restricted, to a dangerous degree. Submergence under water would probably prove particularly advantageous as a means of safely storing sub-bituminous coal of this type.

Summary of University of Illinois Experiments

The facts established by the investigations by the University of Illinois Engineering Experiment Station may be summarized as follows:

1. Freshly mined coal is chemically very active. Certain constituents have a marked affinity for oxygen, with which they enter into combination at ordinary temperatures. While the extent of this reaction depends upon the variety of the coal and the amount of these active constituents, an important factor is the fineness of division, or the sum total of the superficial areas of the particles, and the accessibility of oxygen to the mass.

2. The actual loss of heat value resulting from storage is small. It is evident that upon mining out the coal from the bed certain volatile constituents of the marsh-gas variety are set free. The heat values represented by such exudations are not great. The tendency to absorb oxygen from the air is also a marked characteristic of freshly mined coal. This is in reality a chemical process, and is accompanied by the generation of a small amount of heat, but these heat losses, compared with the total heat available in the coal, are insignificant. Indeed, it may be fairly questioned whether the heat losses are not more apparent than real, since there is an increase of weight due to the absorption of oxygen. Such increase will in itself lower to a corresponding degree the indicated heat value per pound of coal.

3. There is an increase of "fines" or slack resulting from storage, greater with some coals than with others. This,

together with the saturation of the free-burning constituent with oxygen, slows up the fire and gives the appearance of being lacking in heat value. However, with an increase of draft and a correct understanding of the combustion conditions to be maintained, a most excellent over-all efficiency can be secured even from coals that have been in storage for long periods.

4. Bituminous coal can be stocked without appreciable loss of heat values provided the temperature is not allowed to rise above 180 deg. F. Any method of storage, to be successful, must either check or prevent the absorption of oxygen to such an extent that the generation of heat shall not proceed faster than the dissipation and loss of heat due to absorption or radiation.

5. Under-water storage prevents loss of heat values and is not accompanied by deterioration in physical properties, such as slacking. The water retained by the coal upon removal is substantially only that held by adhesion or capillarity.

6. Dry storage is safer and more satisfactory if the fine material is screened out at the storage yard and lumps only, preferably sized, are stocked.

It will be seen from this summary that the most serious part of the problem relates to the matter of spontaneous heating, and probably the least serious phase relates to deterioration and actual loss of heat values. It is certain that at the present time a better understanding of these difficulties has been reached, and there is reason for believing that this better understanding of the fundamental principles involved will lead to some practicable and safe procedure for the stocking of bituminous coal.

The general summary covering the behavior of the coal in steam generation after six years of storage, as set forth in Bulletin 78 of the University of Illinois Engineering Experiment Station, is as follows: (1) Burning weathered coal is largely a question of correct handling and ignition. Under these circumstances it gives as good results as fresh screenings. (2) Weathered coal requires a little thinner fire and more draft than fresh screenings. (3) When using weathered coal, the fuel bed should not approach any nearer to the water-back than from four to six inches, otherwise trouble with clinker is experienced. (4) Practically as high capacity was obtained with weathered coal as with the other coals used, and, if anything, the fuel bed requires less attention.

ACTUAL HEAT LOSS IS SMALL

In this connection attention is called further to the fact that the results obtained and the conclusions presented are based on the heat values in the coal as fired and do not take into account the matter of deterioration. But it has been pointed out that the deterioration is largely apparent in a physical change and that the actual loss of heat value is small. Hence, the efficiency factors developed in the tests may be accepted as fairly representing results obtainable on weathered coal in which the heat loss resulting from weathering is practically negligible.

The facts presented in the bulletin justify the following conclusions: (1) Bituminous coal can be stocked without appreciable loss of heat values provided the temperature is not allowed to rise above 180 deg. F. In fact, there is no appreciable evolution of CO_2 at temperatures below 260 deg. F. (2) The indicated heat loss per pound of coal is due more largely to an increase in weight of a unit mass of coal resulting from the absorption of oxygen than to an actual deterioration or loss of heat units. (3) Freshly mined coal has a large capacity for absorbing oxygen, which combines chemically with both the organic combustible and the iron pyrites present. (4) The combination of oxygen with coal at ordinary temperatures generates a small increment of heat. (5) The rapidity with which oxygen is absorbed depends upon the temperature of the mass and the extent of the superficial area exposed; that is, the fineness of division of the coal. (6) If heat is generated by this slow process of oxidation more rapidly than it is lost by radiation, the acceleration of the reaction causes a rise in temperature which quickly brings the mass up to the danger point. A temperature of 180 deg. F. is named as the danger point because, if the coal reaches that temperature, practically all the free moisture is vaporized and the further rise in temperature will be very rapid. (7) Any method of storage to be successful must either check or prevent the absorption of oxygen to such an extent that the generation of heat shall not proceed so rapidly as to exceed natural heat losses due to radiation. (8) Under-water storage prevents loss of heat values and is not accompanied by deterioration in physical properties, such as slacking. (9) Dry storage is far more safely undertaken if the fine material is screened out at the storage yard and the lumps only, preferably sized, are stocked.

How To Save Coal

The Bureau of Mines, Department of the Interior, recently asked the advice of a number of prominent fuel engineers as to the best way to conserve in the use of coal. Martin A. Rooney, of Detroit, Mich., has the following to say:

In every trainload of coal hauled from the mines to our coal bins, one carload out of every five is going nowhere and worse. In a train of 40 cars the last eight are dead load that might better have been left in the bowels of the earth.

Every fifth shovelful of coal that the average fireman throws into his furnace serves no more useful purpose than to decorate the atmosphere with a long black stream of precious soot. These are not meaningless statistics nor a "goblin" story, but cold facts on a warm subject. At best, one-fifth of all our coal is wasted. And it is shamelessly and needlessly wasted. Instruments and machinery for getting out all of the heat there is in it are not nearly so complicated nor expensive as the cash register which you use to keep tab on your cash receipts or the truck which you operate to clip a few cents off of your delivery costs. Carbon-dioxide temperature and draft are easier subjects to comprehend than bank discount or freight rates.

The moral is, Mr. Coal Dealer, get busy and learn what they are and how to use them. The time is coming when the Government is going to limit the amount of our coal that is dumped down your chute and in the name of fairness, when we must deny fuel to some manufacturer, let it be to him who cannot show that he is going to use it efficiently. In the name of fairness to the miner who digs it, to the heavily burdened railroad which transports it, to a number of our people whose very existence and whose future happiness depend absolutely on the use we make of this most precious of our resources, let us make efficiency the criterion to judge by when we come to determine which shall survive.

And in fairness to the manufacturer who is patriotically operating his properties at nearly to the breaking speed and who is giving up a large part of his profits for the general good, let the Government show him how to conserve this most important of his raw materials. Let us send into our furnace and boiler rooms men who can show our engineers and firemen how to burn their fuel with the least waste, as we have sent them among our fields and orchards to show the farmer how to increase the productivity of his soil.

—By Coffman in New York *American*, with amplification by Weil

HIS SHARE

Early Action Expected on the Administration's New Water-Power Bill

On the night of Jan. 4, 1918, President Wilson held a conference at the White House with members of various committees of the House of Representatives for the purpose of speeding up action in the House on the passage of water-power legislation. The President committed to the care of Representative Pou, chairman of the House Rules Committee and a member of the delegation whose members conferred with him, a copy of a new water-power bill, to be known as the Administration Bill, which attempts to coördinate water-power legislation proposed for several years past in both Houses of Congress, not only on the public domain, but in navigable streams; and it is expected that the result of the White House conference will be that the House Rules Committee will bring in a rule peremptorily requiring the House of Representatives to vote on and pass water-power legislation at an early date.

What is to take place in regard to water-power legislation in the Senate is not yet known, as that body passed the Shields bill, and there is a difference between the provisions of that measure and those of the Administration measure. The Shields measure, in fact, is by way of amendment to the Act of 1906 to regulate the construction of dams across navigable waters and does not deal with water powers on public lands, which are dealt with by a different Senate committee from the Committee on Commerce, which favorably reported the Shields bill. To the fact that there have been so many committees of both the House and the Senate dealing with so many different phases of proposed water-power legislation has been due, more than to anything else, the delay in passing water-power legislation which was promised the country among the so-called "Administration Conservation Measures" when President Wilson took office five years ago. In the House the red tape which has caused this delay seems in a fair way to be cut by the Presidential conference of Jan. 4; for the President, who has had many conferences with members of the House and Senate and their differing committees, without obtaining legislation, committed the new Administration bill not to the chairmen of any of the House committees dealing with water-power matters, but to the chairman of the Rules Committee. The President is reported by those who attended the conference to have explained with the greatest tact to the committee chairmen that he did not know which committee among the water-power committees to entrust with the bill, in view of their differences, and that he would solve the problem by giving it to the Rules Committee, which, as official Washington views it, carried with it the plain implication: "Pass the bill!"

SENATORS EXPECT WHITE HOUSE CONFERENCES

Senators in charge of water-power legislation in the Upper House are also expecting to have White House conferences; it is certain that the Administration bill will be introduced in the Senate or that its provisions will come before a Senate committee in some form, so that when the House passes the Administration bill there may be a conference between the House and the Senate, giving opportunity to mold the differences between the Administration bill, the Shields bill already passed by the Senate, and the provisions of any measure relating to the public lands which may come from the Lands Committee of the Senate, in case there is no agreement in the Senate to substitute the Administration bill for the Shields bill. It is not at all certain that Senators will accept the Administration bill, and there are some who will not fail to exercise the "I object" made famous by "senatorial courtesy," unless they can be made to see that the safety of the country imperatively demands the passage of water-power legislation at once because of the shortage of coal and consequently of power, which was President Wilson's impelling motive in committing the new Administration bill to the House Rules Committee.

Although most of the water-power legislation delay has been due to Congress, some of it has been due to opposing views held by members of the Cabinet. These views have now been reconciled in the new Administration bill, which provides for a water-power commission to be composed of three Cabinet officers—the Secretary of the Interior, the Secretary of Agriculture and the Secretary of War. It provides for an executive officer of the commission, who shall be appointed by the President for a term of five years. It provides for the payment of rentals, a feature to which there has never been objection of consequence by any interest, and it grants licenses for water power on public lands as well as public streams for a term of 50 years. At the end of the license period the licensee will be allowed to renew the license and remain in undisturbed possession until the proposed commission shall have done one of three things: First, issue new licenses under laws at that time applicable; second, give licenses to new licensees who shall pay for the fair value of the property; third, take the property over upon paying a fair value, the fair value defined to include all work and main transmission lines plus severance damages for all property not taken over and damaged by reason of severance.

ENHANCEMENT OF VALUES NOT PROVIDED FOR

The new Administration measure does not include any allowance for enhancement of values on land, or water rights, or for any good will for a going concern, etc. It provides for alteration, amendment or repeal by Congress, Congress expressly reserving such rights; but in case of alteration, amendment or repeal, such shall not extend to the licensees who have exercised rights or spent money under the bill.

The bill was drawn by General Black and Colonel Keller, of the Army Engineer Corps, representing the War Department; Edward C. Finney, water-power expert for Secretary Lane; former Representative Lathrop Brown, of New York, now a special assistant to Secretary Lane, representing the Interior Department; and O. C. Merrill, chief inspector of the Forest Service, representing the Agricultural Department, who several years ago compiled a mammoth report on water-power companies, their banking affiliations, etc. Present at the White House conference on the night of Jan. 4 were Thetus W. Sims, chairman of the House Committee on Interstate and Foreign Commerce, who has recently succeeded Judge Adamson in that position; Scott Ferris, of Oklahoma, chairman of the House Public Lands Committee; Asbury F. Lever, of South Carolina, chairman of the House Agricultural Committee; Edward W. Pou, of North Carolina, chairman of the House Rules Committee; and Finis J. Garrett, the ranking member of the House Rules Committee. Representative Garrett and Representative Sims, as well as Senator Shields, are Tennesseeans, so that Tennessee will have much to say, it so falls out, as to the passage of water-power legislation by the present Congress.

At the Presidential conference it was agreed that a committee of five members each from the House Committee on Interstate and Foreign Commerce, Agriculture and Public Lands, or fifteen in all, should be created to compose differences as to the various bills which have been under consideration heretofore in the House and to bring together such radical views as have been expressed by Representative Ferris during public debate on water powers with the more moderate views as to water-power development expressed by others. The committee of fifteen, it is felt in Washington, will be materially aided in its labors by the fact that after mature deliberation, advice and conference, President Wilson himself has presented a bill upon which he believes all can agree.

It is gross negligence for the operator of an electric-power plant to permit a switchboard carrying a dangerous voltage to remain exposed near a passageway used by employees, rendering him liable for resulting injury to or death of such an employee. The fact that an employee killed under such circumstances had been warned against the danger of coming in contact with the appliances did not necessarily charge him with contributory negligence where he inadvertently came in contact with the switchboard while stepping aside to avoid another employee who was passing with tools on his shoulder. (Kansas City, Mo., Court of Appeals, Lightner vs. Dunham, 195 Southwestern Reporter, 1055.)

A. S. M. E. Presented with Bust of Admiral Isherwood

At its annual meeting in December, 1917, the American Society of Mechanical Engineers was presented with a portrait bust of Admiral Benjamin Franklin Isherwood, who was for many years, up to the time of his death, an honorary member of the society. The bust was a gift from a number of the friends and admirers of the admiral. The presentation address was to have been made by Commodore George W. Magee, U. S. Navy, who had been an old friend and assistant of Admiral Isherwood; unfortunately, however, Commodore Magee was taken ill, and that pleasant duty devolved upon W. M. McFarland.

Mr. McFarland pointed out that the special glory of Admiral Isherwood's work was that he helped to establish a number of the important basic principles of the science of engineering. He stated that the first reproduction of actual indicator cards from a marine engine published in any book was in Isherwood's work on "Engineering Precedents," published about 1856. He said further:

BUST OF ADMIRAL ISHERWOOD

> His reports of experiments are models of what such reports should be. They include a complete description of the apparatus; and the log of the experiment, in each case, gives all the data which could be observed, whether they were immediately applicable to the purpose of the experiment or not. The result of this is that these reports constitute a mine of valuable information; and other engineers, many years after, seeking information on an entirely different line from that for which the experiment was conducted, find in the complete and careful record just the information they want, and which often can be found nowhere else.

The written address of Commodore Magee, which was read by Mr. McFarland, referred to the great value of Isherwood's experimental work on such subjects as the expansive working of steam, screw propellers, the use of superheated steam and the use of forced draft. Commodore Magee characterized Admiral Isherwood as "the greatest marine engineer who has thus far appeared in our country," and "not only a great engineer, but a great administrator and executive."

Dr. Hollis, president of the A. S. M. E., in accepting the bust on behalf of the society, spoke of his personal acquaintance with Admiral Isherwood at the Naval Academy and said he considered his service for the admiral as perhaps the proudest of his life. Continuing, he said:

> I think of him as perhaps the father of our great research laboratories in engineering, as his investigations in connection with steam engines and with boilers preceded all of our schools of mechanical engineering. I think of him also as the father of high speed on the sea. Few people realize that it was Benjamin F. Isherwood who during the Civil War planned and carried to its completion the first ocean greyhound, a ship which went outside along the Jersey coast and made four hundred miles in one day with ease, something that was not equaled again for twenty years.

Annual Report on Locomotive-Boiler Inspection

The annual report of the chief inspector of locomotive boilers for the fiscal year ended June 30, 1917, shows a considerable increase over the previous year in the number of accidents, injuries and casualties due to locomotive-boiler defects and explosions. Much of this increase is explainable on the grounds of the unusual operating conditions, and the shortage of labor and material for suitable repairs. On the other hand, some carriers appeared to consider the use of defective locomotives excusable because of the congestion of traffic. The number of locomotives inspected during the year was 47,452, which is considerably fewer than the year before; and of those inspected, 54.5 per cent. were found defective, an increase of 7.5 per cent. over the previous year. The number of locomotives ordered out of service was 3294. Crown-sheet failures due to low water were responsible for almost three-fourths of the 62 fatalities during the year, and as might naturally be expected, engineers and firemen were the chief sufferers. Of the defects discovered by inspection, broken stay-bolts, faulty injectors and connections, and defective brake equipment headed the list. The report forms another strong argument in favor of the efficient periodic inspection of high-pressure boilers.

An American pipe line played an important part in the recent capture of Jerusalem according to the statement of Maj. Gen. F. B. Maurice, chief director of military operations at the British war office. The campaign which led to the fall of Jerusalem was carried out mainly by British territorial troops supported by small bodies of Australian and New Zealand mounted men and British yeomanry. "In the campaign as a whole," he said, "the great accomplishment has been not the defeat of the Turks, but the conquest of the Sinai Desert. The troops who fought at Gaza drank water from Egypt pumped through an American pipe line and were supplied over broad-gage railroad laid across the 150 miles of the Sinai Desert, which has defeated almost everybody who tried to conquer Egypt for centuries. Every ounce of material for the pipe line, the railroad and the other works came either from Great Britain or from the United States. The fall of Jerusalem was made possible by industry, organization and by the help of material from the United States."

Peat production in Norway in 1914 was 12,000 tons, and 22,000 tons in 1916, but the production in 1917, it is said, will probably go up to 100,000 tons. In Denmark, in 1915, the production was 90,000 tons, in 1916 200,000 tons, and in 1917 it is hoped to produce 500,000 tons. Sweden produced 100,000 tons in 1916. There are 216 peat machines now working in Norway, as compared with 55 in 1916 and 36 in 1914. Among the machines in use are two automatics; these cost £2700 apiece, and can each be handled by two men, the daily output per machine being 30 to 40 tons of peat.—*Gas and Oil Power.*

TESTS OF OXYACETYLENE-WELDED JOINTS IN STEEL PLATES

Bulletin No. 98 of the University of Illinois Engineering Experiment Station, by Herbert F. Moore, research professor of engineering materials, treats of tests of oxyacetylene-welded joints in steel plates from 0.14 in. (No. 10 gage) to 1 in. in thickness. Welds made by skilled workmen in a plant especially equipped for oxyacetylene welding were tested for their resistance to tensile, bending and impact stresses. For joints made with no treatment after welding, efficiency for static tension was found to be about 100 per cent. for plates one-half inch in thickness or less and to decrease for thicker plates. When account was taken of the additional thickness at the point of fracture—that is, when the efficiency was computed upon the cross-sectional area of the metal ruptured—the efficiency was not greater than 75 per cent. The joints were strengthened by working the metal after welding and were weakened by annealing at 800 deg. C. (about 1400 F.). Practically the same is true of the bending or repeated-stress test. The impact tests show that oxyacetylene-welded joints are decidedly weaker under shock than is the original material. For joints welded with no subsequent treatment the strength under impact seems to be about half that of the material. If the welded joint is worked while hot, the impact-resisting qualities are slightly improved though this does not make the joint equal to the original material in impact-resisting quality, which is little affected by annealing from 800 deg. C. In general the test results tend to increase confidence in the static strength and in the strength under repeated stress of carefully made oxyacetylene-welded joints in mild-steel plates.

THE J. E. ALDRED LECTURES ON ENGINEERING PRACTICE

A course of lectures on "Engineering Practice" was established about a year ago at Johns Hopkins University through the generosity of J. E. Aldred, and the first series, given by prominent practicing and operating engineers, has recently been published. These lectures, nine in number, present the essential features of planning, construction and operation of modern engineering projects and, being open to the public, were well attended by the engineers of Baltimore.

The subjects in the order in which the lectures were delivered, from Mar. 16 to Apr. 20 inclusive, are as follows: The Operation of a Hydro-Electric Plant, by A. E. Bauhan, station superintendent, Pennsylvania Water and Power Co., Holtwood, Penn.; Some Things Engineers Should Know Concerning the Rudiments of Corporate Finance, Ralph D. Mershon, consulting engineer, New York; The Development of Power from the Standpoint of the Boiler Room, C. F. Hirshfield, chief of research department, Detroit Edison Co., Detroit, Mich.; Power and Service in Industrial Plants, R. J. S. Pigott, superintendent of motive power, Remington Arms Co., Bridgeport, Conn.; Gas Manufacture, Construction and Operation, George P. Marrow, assistant engineer, in charge of Gas Manufacture, Consolidated Gas, Electric Light and Power Co., Baltimore; Rapid Transit Problems in American Cities, George Staples Rice, engineer of the Sixth Division of the Public Service Commission, New York; Some Practical Problems Met With in the Design and Construction of Bridges and Similar Structures, W. W. Pagon consulting engineer, Baltimore; Experimental Engineering, Particularly the Construction of Testing Stations on Water and Sewerage Problems, Langdon Pearse, division engineer, Sanitary District of Chicago; Public Utility Engineering and Finance, Herbert A. Wagner, president, Consolidated Gas, Electric Light and Power Co., Baltimore.

A limited number of paper-bound copies of this course of lectures, about 250 pages 6 x 9 in., including numerous illustrations with additional folders of charts, maps and diagrams inserted, can be obtained from the Johns Hopkins Press (Baltimore, Md.) for $1 each.

Personal

C. P. Coleman was elected president of the Worthington Pump and Machinery Corporation at a meeting of the Board of Directors held on Dec. 31.

R. H. McLeod has been appointed general superintendent of the Philadelphia and Titusville plants of the Philadelphia Rubber Co., being promoted to this position from that of mechanical engineer. He is a graduate of Columbia.

Edward H. Tenney has been promoted from assistant chief engineer to chief engineer of the Union Electric Light and Power Co., of St. Louis, succeeding John Hunter, who is in charge of the Government emergency ship construction of the New Jersey district.

John Hayes Smith, consulting engineer of Milwaukee, has accepted a position as assistant engineer to the Public Service Commission of Pennsylvania. Mr. Smith became associated with the Westinghouse Electric and Manufacturing Co. shortly after graduation from Columbia University, remaining in their employ about six years. He was the first manager of the "Electric Journal," Pittsburgh, and later became editor of the "Electrical Age," New York. He was with the Milwaukee Electric Railway and Light Co. for two years.

Engineering Affairs

The Philadelphia Section of the A. S. M. E. will hold a meeting on Feb. 26, at which Carl G. Barth will present a supplement to "Taylor's Art of Cutting Metals."

American Association of Engineers—Edmund F. Perkins, consulting engineer, Chicago, and president of the American Association of Engineers, will address the New York Chapter of the association at the Hotel McAlpin, on Tuesday, Jan. 15, 8 p.m., on the subject of "National Association Service for Engineers." All interested are cordially invited.

Miscellaneous News

A Four-Inch Tube in a boiler at the Philadelphia Navy Yard blew out on Jan. 1, killing two men, injuring six severely and one slightly. It is believed the explosion was due to a defective tube.

The Boiler of a Freight Locomotive on the Chesapeake and Ohio R.R. exploded at Marmet, W. Va., on Dec. 22, killing the fireman and injuring the engineer. The cause of the explosion is not known.

A Boiler Exploded at the plant of the Beaver Clay Co., at New Galilee, Penn., on Dec. 26, causing considerable damage to the boiler room and surrounding structure and severely injuring a workman who was near the boiler when it let go. The cause of the explosion is not known. The damage done was estimated at $2000. Because of a partial suspension of work during the Christmas period many of the employes were not in service, which fortunately accounts for lack of casualties perhaps.

Large Providence Turbine Started—The 45,000-kw. Westinghouse cross-compound turbine at the South Street Station of the Narragansett Electric Lighting Co., Providence, R. I., was started for the first time Wednesday morning, Jan. 9. The turbine is perhaps the largest in the world in point of dimensions, although the two-cylinder turbine at the Duquesne plant, Pittsburgh, is of the same capacity. The Providence turbine has a double-jet Leblanc condenser, which "Power" will describe after it has been in service long enough to determine what performance it will give.

U. S. Requisitions Power Plants at Niagara Falls—In order to assure an adequate supply of power for establishments engaged in war work at Niagara Falls and Buffalo, the Government has requisitioned the electric power produced, imported and distributed by the Niagara Falls Power Co., the Hydraulic Power Co. of Niagara Falls and the Cliff Electrical Distributing Co. Canadian demands that approximately 100,000 hp. of current imported from the Canadian side be applied exclusively to war work were said to have been a determining factor in the Government's decision to requisition all power. About 110 factories not working directly on war contracts will be obliged to curtail their power somewhat and use it at times when munition factories are making their smallest demand. They will also substitute steam for electricity as much as possible.

England Out of Gasolene?—Our London correspondent writes: "Apparently while you are not short of petrol, we in England are. Instead we use gas, a bag to contain a charge being placed on top of the lorry, omnibus or other vehicle. Depending on the thermal value of the gas, the equivalent is about 250 cu.ft. to the gallon of petrol. Some busses have gas bags to hold about 700 cu.ft. In one instance, motor busses carrying 35 people run a mile on 60 cu.ft. Compression of gas has been suggested, but this means special machinery and special cylinders to support the increased pressure. The cost of charging varies according to the district. To take Birmingham as an example, the minimum fee is 1s. (25c.), this being the cost of 250 cu.ft. of gas." It seems likely, therefore, that gasoline engines, whether for automobiles, stationary, electric-generating or pumping sets, are now compelled to use gas.

Business Items

The Ridgway Dynamo and Engine Co., of Ridgway, Penn., has appointed the Blake Electric Manufacturing Co., 1 Rowes Wharf, Boston, Mass., as its sales representative for the New England States.

The Little Giant Truck Co. is the name of what was formerly the motor-truck department of the Chicago Pneumatic Tool Co., which on account of its growing proportions has branched off as a separate organization. The new company is owned and controlled by the Chicago Pneumatic Tool Co.

Albany Grease is celebrating its fiftieth anniversary. In 1868 the Albany Lubricating Compound and Cup Co. was founded at Albany, N. Y., by Adam Cook. The name Albany Grease was given to Albany Lubricating Compound by the engineers of the country, who quickly gave it a name of their own make. In four years the small plant at Albany became too small to take care of the business, and in 1872 larger quarters were secured along the river front at 231 West St., New York City. Nine years later the business was moved to still larger quarters at 313 West St. Still the business grew, until, by the purchase of neighboring warehouses, the Albany plant extended clear through the block from West to Washington St. After a stay of 30 years the West and Washington St. plant was abandoned, and the modern commodious plant at 708-10 Washington St. was placed in service. Many satisfied customers unite in wishing Albany Grease many happy returns of the day.

Trade Catalogs

Files Hand Stoker. The Files Engineering Co., Inc., Providence., R. I. Catalog. Pp. 8; 6 x 9 in.; illustrated.

Ellison Draft Gages. Lewis M. Ellison, 214 Kinzie St., Chicago, Ill. Pamphlet. Pp. 36; 3½ x 6 in.; illustrated

Westinghouse Motors and Generators for Direct-Current Circuits. Westinghouse Electric and Manufacturing Co., E. Pittsburgh, Penn. Catalog No. 30. Pp. 78; 8½ x 11 in.; illustrated.

Getting Maximum Pulley Efficiency. The American Pulley Co., Philadelphia, Penn. A pamphlet containing data and information compiled by this company relating to belt pulleys. Pp. 38; 6 x 9 in.; illustrated.

Falls Automatic Engine Stop. Falls Machine Co., Sheboygan Falls, Wis. Catalog Pp. 24; 6 x 9 in.; illustrated This contains information regarding the operating of overspeeding engines and shows application of engine stops.

Reverse-Phase Circuit Breakers. The Palmer Electric and Manufacturing Co., Boston, Mass. Bulletin M1; pp. 4; 6 x 9 in.; illustrated. Describes circuit-breakers for protection of polyphase motors against single-phase and reverse-phase operation.

Just About Boilers is the title of a pamphlet issued by the Badenhausen Co., 1425 Chestnut St., Philadelphia, Penn., which gives comparisons of principles of current boiler designs and details of construction of the Badenhausen boiler. Pp. 32; 8½ x 11 in.; illustrated.

Electric Welding. The Wilson Welder and Metals Co., 52 Vanderbilt Ave., New York. Catalog No. 2. Pp 64; 6 x 9 in.; illustrated. This describes in detail the Wilson electric welding system and specially prepared metals. Blueprints showing layout of complete equipment are included.

Automatic Pumps and Receivers. Worthington Pump and Machinery Corp., 115 Broadway, New York. Bulletin D-1301. Pp. 12; 6 x 9 in.; illustrated. Describes a number of types of apparatus manufactured by the Deane Works of the Worthington corporation for maintaining free and unobstructed circulation of steam in heating systems and machinery using steam.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Jan. 10, 1918	One Year Ago	Jan. 10, 1918	One Year Ago
Buckwheat	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Jan. 10, 1918	One Year Ago	Jan. 10, 1918	One Year Ago
Clearfields	....	$3.00	....	$4.25—5.00
Cambrias and Somersets	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.69. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Jan. 10, 1918	One Year Ago	Jan. 10 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$6.00—7.00
Buckwheat	4.30—5.00	2.75	5.50—6.00	5.50—6.00
Rice	3.75—3.95	2.20	4.50—5.00	5.00—5.50
Barley	3.25—3.50	1.95	4.00—4.25	3.75—4.00
Boiler	3.50—3.75	2.20	....	....

Bituminous smithing coal, $4.50—5.25 f.o.b.

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide		Independent
	Jan. 10, 1918	1 Yr. Ago	Jan. 10, 1918	1 Yr. Ago	1 Year Ago
Buckwheat	$3.15–3.75	$2.00	$3.75	$2.90	$4.15
Rice	2.65–3.65	1.25	3.65	2.15	3.35

Williamson, Franklin rate St. Louis, 87½c.; other rates, 72½c.

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump and Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba	2.40	2.65	2.15

Government figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

PROPOSED CONSTRUCTION

Ariz., Kingman—The Desert Power and Water Co. plans to extend its transmission line to the Hackberry Consolidated Mill. Estimated cost, $90,000. A new line will also be extended to the Cyclopic, near Chloride. F. A. Wilde, Jr., Mgr.

Calif., Los Angeles—City has plans under consideration for the erection of power plant No. 2 in San Francisquita Canyon. W. Mulholland, Ch. Engr. Estimated cost, $750,000.

Calif., Mare Island—(Vallejo P. O.)—(Official)—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids to deliver at Navy Yard, Mare Island, under Schedule No. 1639, 400,000 ft. plain bell wire.

Iowa, Eddyville—City plans an election soon to vote on $7000 or $8000 bond issue for improvements to the electric-lighting system.

Mass., Boston—(Official)—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for delivering at Navy Yard, Boston, under Schedule No. 1640, brass gate valves, flanged gate valves and globe angle flanged valves.

Mass., Ipswich—The Newburyport Gas and Electric Co. plans to build a transmission line through certain streets in the city. C. S. Spaulding, Newburyport, Supt.

N. C., Graphiteville—The General Graphite Co., Birmingham, Ala., plans to build a hydro-electric plant here. Estimated cost, $75,000.

N. J., Jersey City—The American Sugar Refining Co., 117 Wall St., New York City, is having plans prepared for the extension and alteration of its power house on Washington St. Estimated cost, $10,000.

N. J., Newark—The Butterworth-Judson Co., Roanoke Ave., plans to build a 1-story, 87 x 94-ft. boiler house. Estimated cost, $18,000.

N. Y., Andover—City has plans under consideration for the erection of an electric-lighting plant.

N. C., Tuxedo—The Blue Ridge Power Co. plans to build a hydro-electric plant on the Green River. Estimated cost, between $800,000 and $900,000.

Penn., Philadelphia—Shane Bros. & Wilson, Bourse Bldg., is having plans prepared by J. M. Whitham, Arch., for the erection of a new 1-story, 35 x 40-ft. power house in connection with its plant on 63rd and Market Sts.

Penn., Pottsville—The Eastern Pennsylvania Light, Heat and Power Co. has petitioned the Public Service Commission for permission to issue $10,500 in bonds; the proceeds will be used in improvements to its system. W. B. Rockwell, Mgr.

Penn., Philadelphia—The United States Government plans to build a 1-story power house at the Frankford Arsenal.

Penn., Reading—The Reading Transit and Light Co. has been granted permission to issue an appropriation of $150,000; the proceeds will be used in extensions and improvements to its system. W. S. Barstow, Mgr.

Penn., West Chester—The Philadelphia Suburban Gas and Electric Co. plans to build a transmission line from its electric plant on the Schuylkill River at Crombie to Coatesville. J. D. Shattuck, Philadelphia, Mgr.

Penn., White Haven—The Wilmot Engineering Co., Hazleton, plans to build several additions to its plant including new power stations.

Tex., McAllen—The Rio Grande Public Service Corporation plans to install new machinery and equipment in its electric-lighting and power plant. Estimated cost, $40,000.

Tex., San Benito—The Commonwealth Electric Light and Water Co. plans to enlarge its power house and install new equipment including a new 100-hp. engine in its electric-light and power plant here.

Wash., Puget Sound—(Bremerton P. O.)—(Official)—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for delivering at Navy Yard, Puget Sound, under Schedule No. 1641, low pressure, iron, steam and water unions and brass composition, steam and water unions.

B. C., Trail—The West Kootenay Power and Light Co. plans to extend its transmission line to the plant of the Canada Copper Co., Princeton, about 110 miles. J. B. McDonald, Rossland, Gen. Supt.

Ont., Bartonville—Barton Township plans to purchase electrical equipment. Estimated cost, $55,000.

Ont., London—The Board of Utilities plans to build a brick and steel addition to its hydro sub-station. Estimated cost, $35,000. E. V. Buchanan, City Hall, Gen. Mgr.

POWER

Vol. 47 NEW YORK, JANUARY 22, 1918 No. 4

How Engineer Tim Got a Raise of Pay and Promotion

Contributed by M. E. GRIFFIN

TIM had been chief operating engineer in a cotton mill for fifteen years, and during that time had received only one raise of pay, and that mainly because of his heroic work during a fire.

Some time ago he decided to ask for a raise. Nerving himself for the ordeal, he finally had courage enough to go to the manager's office and in a straightforward way stated his case. The manager answered that the firm always recognized him as a good, faithful, conscientious engineer and felt proud of the care he took of the power plant, but owing to the increased cost of material and generally high running expenses, it was not possible to raise his pay, at least at that time.

Tim returned to the engine room somewhat downhearted, but he knew that it would be useless for him to try for a job elsewhere, as the pay would not be greater and he would have to start in on a new job with machinery perhaps new to him, whereas he knew all about his present power equipment.

TIME AND AGAIN he asked himself the question: *"How can I make myself more valuable to my employers and in turn get more pay for increased efficiency?"* He had been reading many articles on how engineers increased the efficiency of their plants and decided that perhaps it was possible for him to do likewise. It was true that his engines always ran well and none had better care, the firm often remarking on the low cost of repairs.

The power plant consisted of one 600-hp. cross-compound Corliss engine and a 250-hp. single-cylinder Corliss, each noncondensing and belted to separate lineshafts. There was also a 600-ft. steam-driven air compressor of old design, which was always considered a "steam hog." Air pressure was 80 lb. and steam pressure on boilers 125 lb. gage.

Tim purchased a book on engine testing and learned how to figure steam consumption from indicator cards, because he wished to make a test and ascertain if his plant was as efficient as it should be.

He had no means of measuring steam because his plant was noncondensing and to "rig up" would cost too much for equipment—more, he knew, than his firm would allow—therefore steam consumption from indicator cards was the nearest he could approach true conditions.

While he was making elaborate preparations for indicating the different units, he became so enthusiastic that he even gave the office boy a package of cigarettes for spreading the news around the office that great "doings" for increased efficiency were going on in the power plant.

THE CARDS from the cross-compound were very good, showing good distribution of steam and figured 20½ lb. of steam per indicated horsepower-hour, which was relatively close to the engine builder's guarantee.

The single-cylinder engine's cards, while showing good valve setting, figured 29 lb. of steam per i.hp.-hr., which was very much higher than builder's guarantee. This was accounted for by the early cutoff shown on the cards, proving that this engine was considerably underloaded and therefore wasteful accordingly.

The air-compressor cards figured an average of 37 lb. steam per i.hp.-hr. and showed a cutoff of about 75 per cent. of the stroke, which meant that the work done by the expansion of steam was practically nothing.

Summing up the steam consumption for the three units, 20½ lb. + 29 lb. + 37 lb. = 86½ lb. of steam per i.hp.-hr., and as the coal had an evaporation value of one pound of coal per 7½ lb. of steam, it was no wonder the firm was complaining about the monthly coal cost.

This convinced Tim that, while for fifteen years he thought he had an economical plant, he was only fooling himself and incidentally throwing his firm's money into the boilers, as he termed it.

After a couple of days' thought, he asked permission to make a few changes that he believed would increase the efficiency of the power plant with very small expenditure of money, stating that he could do the work himself at "odd" times. The superintendent gave him permission to do anything within reason that would reduce the coal consumption.

TIM REASONED THUS: "The cross-compound is the only economical unit, and I'll leave it alone; the single-cylinder is underloaded, and I'll have to build up a load somehow; the air compressor is overloaded and playing h— with the coal pile."

On the air compressor there were two balance wheels, each wide enough for a belt to drive it and so located that it could easily be belted to the lineshaft driven by the single-cylinder engine.

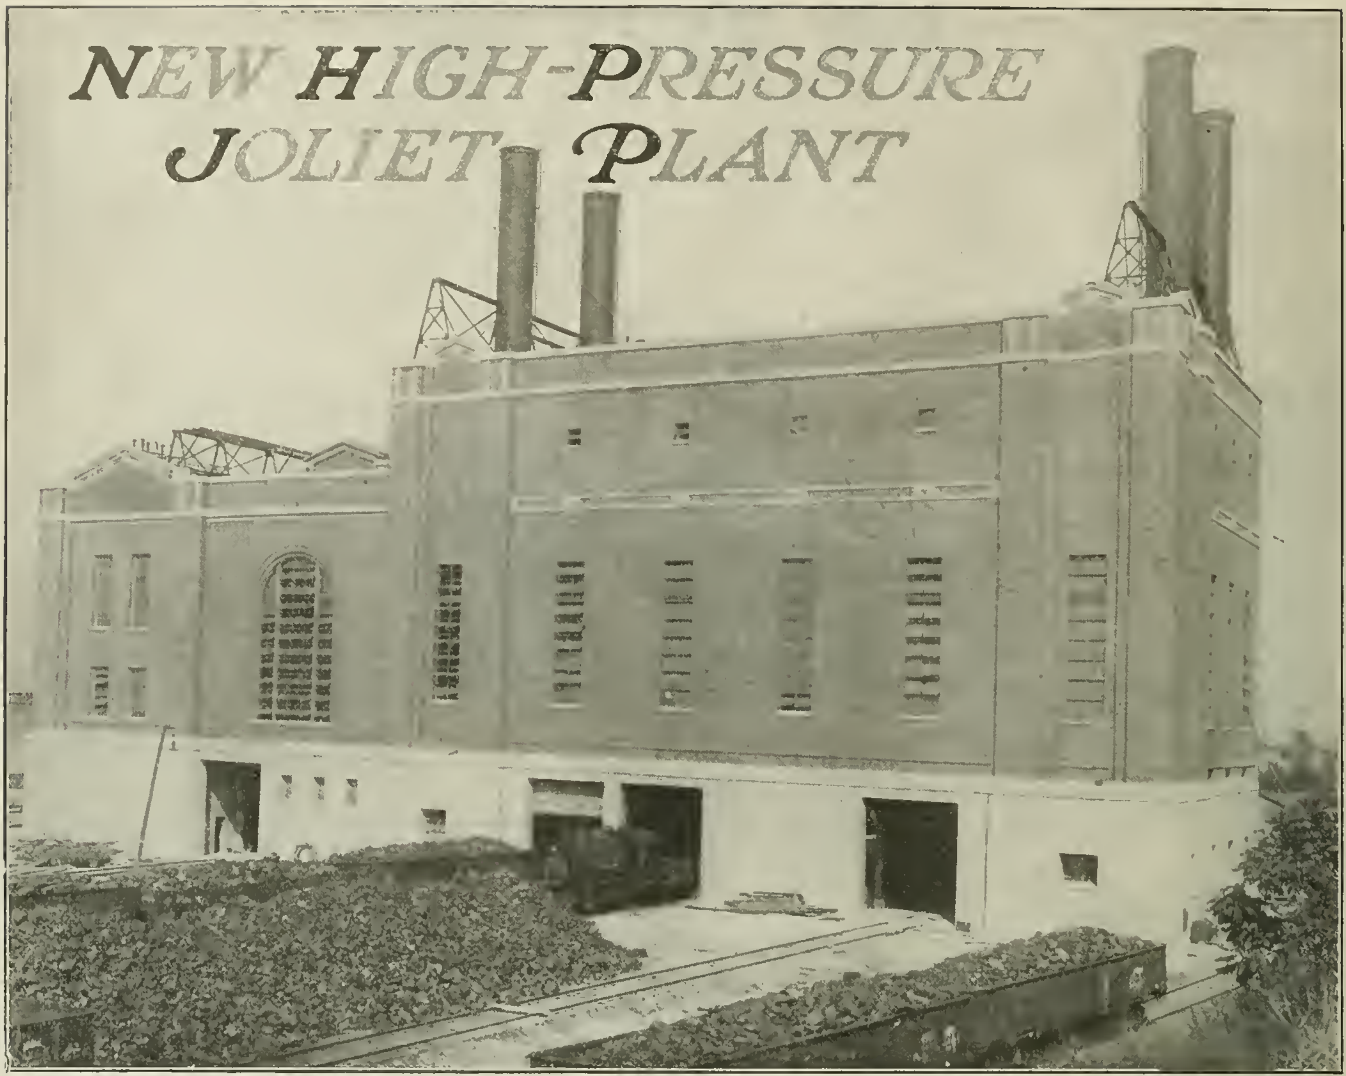
This seemed like an inspiration. He took the steam piston out of the air compressor and turned it down with a groove to hold babbitt and babbitted the lower circumference one-third the way around so as to act as a tail-rod crosshead, using the steam cylinder with heads removed as a tail-rod guide. He then procured a pulley of suitable size and mounted it on the lineshaft driven by single-cylinder engine, belted up the air compressor and shut off its steam line, letting the single-cylinder Corliss drive the belted air compressor.

His new set of indicator cards from the single-cylinder unit, while showing a slight overload, figured a fairly economical steam consumption and good distribution of steam and the 37 lb. per i.hp.-hr. of the air compressor was a thing of ancient history. Tim was the happiest man in North Carolina. Why?

ABOUT A WEEK after the change was completed, the manager sent for him. Tim was surprised at his offering him a cigar, and more so when he showed him a chart of coal consumption, week by week, covering year after year, and what the saving had been during the past week.

"Tim," said he, "you asked for a raise of pay a while ago, and we could not afford it, although we would willingly have granted it if conditions warranted it. We have been keenly interested in what you have been doing since, and the results are a revelation to us. You have initiative and can think for yourself. We are not going to give you a raise of pay as chief engineer." Tim began to feel sick at heart. After all his trouble, no raise! "No, not as chief engineer. At a directors' meeting this afternoon we appointed you general superintendent of this plant, your duties to begin at once, and you have free rein to use your best judgment in increasing the efficiency of any and every department according to your own ideas. You are the efficiency expert we have been advertising for and could not locate."

NEW HIGH-PRESSURE JOLIET PLANT



Boilers designed for 350 lb. pressure will deliver steam to the turbines at 300 lb. gage and 225 deg. F. of superheat. An all-steel horizontal-tube economizer is placed above and integral with each boiler. Extra-heavy piping, special welded joints and steel fittings are employed. First 10,000-kw. unit is now in operation and second under erection.

TO CARE for a rapidly increasing load in a territory covering thirteen counties, the Public Service Co. of Northern Illinois is adding the new Joliet plant, shown in the headpiece, to its list of generating stations. It is situated about three miles south of the city on the Des Plaines River, on 40 acres of land between the Atchison, Topeka & Santa Fe and the Chicago & Alton railroads. This location is adjacent to two railroads tapping the coal fields of Illinois and has at hand an abundant supply of water. A property plat is shown in Fig. 1. The initial portion of the station is to contain two 10,000-kw. generating units. Later, as the load demands, the building will be extended to accommodate additional and larger units.

In the new plant the outstanding feature is the high steam pressure—300 lb. at the turbine and approximately 325 lb. at the boiler, superheated 225 deg. This is about 75 lb. higher than common in modern stationary practice and is a notable step in the recent movement to improve economy by raising the upper limits of the cycle. It seems generally agreed that in the condenser there is little more to be gained. Higher steam temperatures to widen the operating range up to the limitations of the metal employed and the construction of the equipment offer the greater opportunity.

Although the boilers are of the standard Babcock & Wilcox cross-drum type, they are built heavy to withstand the high pressure. The plates in the boiler drum are $1\frac{5}{16}$ in. thick, the longitudinal seam being a butt and double cover strap quadruple-riveted joint. The heads are secured by two rows of rivets. Tubes of No. 7 gage, as compared to No. 10 for 200-lb. pressure, are used. All high-pressure steam piping is extra-heavy and of relatively small diameter owing to the density of the steam. With steam at a temperature of 650 deg. rigid construction was avoided. The length of straight runs has been limited, and numerous long-radius bends are employed to provide for expansion. All fittings are of steel, the manifolds used in connection with the boiler leads having been cast and the smaller fittings forged. On pipes above 4-in. diameter a special bolted joint with a welded seal at the periphery is used.

A notable feature is the installation of individual all-steel horizontal-tube economizers, the first of their kind in this country. The economizer is placed above and integral with the boiler. The economizer tubes have a 5-deg. slope. With no dampers between, so that the gases pass directly from one to the other, it is really one stage of the boiler unit. See Fig. 3. Furnace gases pass from the economizer at such low temperatures as to permit unlined steel stacks, the latter being coated with an asphaltic paint adapted to high temperatures.

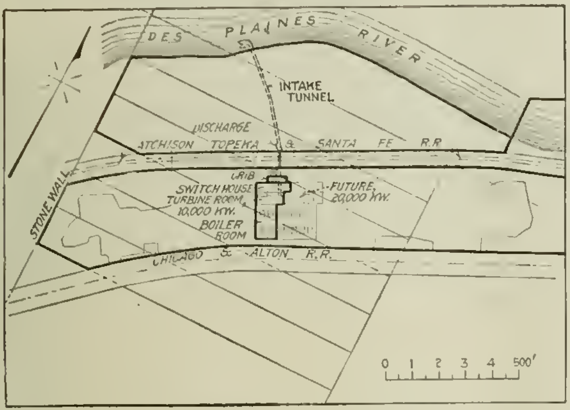


FIG. 1. PROPERTY PLAT, JOLIET STATION

Another feature of the plant is a basement entirely above ground, the main operating floor being the second story of the building. A solid rock footing was already available and excavation would have been costly. Besides, the construction gives headroom for the coal and ash cars operating at the ground level and eliminates ash conveyors. There is gravity flow from the overhead coal bunker to the stokers, and the ashes are delivered directly from the hoppers under the stokers to railway cars.

Outside of the small stoker engines held as reserves for motor drives, there is no reciprocating machinery in the station. All pumps are of the centrifugal type and motor-driven with the exception of the boiler-feed and one service pump operated by turbines. With little exhaust steam available to heat the feed water, provision is made to bleed steam under thermostatic control from the fourth stage of the main turbine, where the pressure is sufficient for this purpose. Another feature is to utilize the condenser for drawing boiler makeup from the fresh-water reservoir. The water enters the condenser and with the aid of the condensate pump is passed in the usual way to the heater.

With the compact arrangement of boiler and economizer and the steel casing over all, radiation and air leakage should be reduced to a minimum. An exceptionally high boiler efficiency should be maintained.

Architecturally, the building is substantial and of pleasing design, as the headpiece of this article shows. A skeleton steel frame supports walls of vitrified brick resting on concrete base walls. Floors are of reinforced concrete. In the turbine room the walls are lined with white glazed tile with a 5-ft. dado of dark-green tile. In plan the building is irregular with maximum dimensions of 134 x 244 ft. As the entire plant is above the ground level, the height is greater than usual. The basement floor is about six inches above ground level, the boiler-room floor is 28 ft. higher and to the top of the monitor roof an additional 60 ft. Under the turbine room is a 22-ft. basement. The height from the main floor to the crane rail is 30 ft., and the clear space to the bottom of the roof girders measures 40 ft. At one end of the building are temporary walls so that the station may be extended easily for additional equipment.

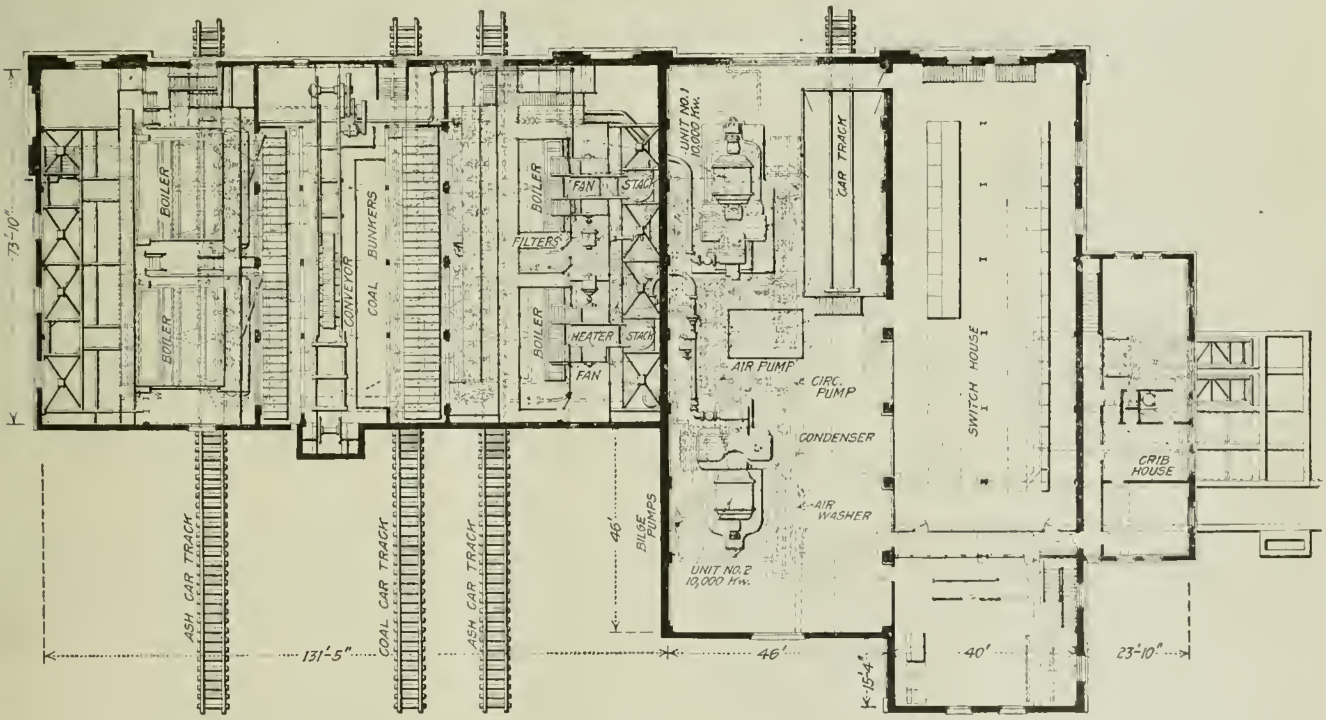

FIG. 2. GENERAL PLAN OF STATION

The station is arranged on the unit plan. For each 10,000-kw. generating unit there will be two cross-drum water-tube boilers, each having 9919 sq.ft. of steam-making surface, a built-in superheater with 3100 sq.ft.

and an economizer containing 6730 sq.ft. of surface. There are now three boilers in the plant, but when the second generating unit is installed, a fourth boiler will be added. Under ordinary conditions when a good grade of Illinois coal is available, it is the intention to use three boilers to carry the two generating units, leaving one boiler in reserve. With inferior coal the four boilers will probably be needed.

With three boilers serving two generators there will be 1.49 sq.ft. of active steam-making surface per kilowatt of generating capacity, or on the basis of 10 sq.ft., one boiler-horsepower will serve 7.67 kw. This does not take into account the economizer. Each boiler, with its steel casing, masonry setting and retreating back, covers at the floor line an area of 294 sq.ft., or 0.296 sq.ft. per horsepower (10 sq.ft.) of rating. Including the overhang the area increases to 0.472 sq.ft. per horsepower, and to the stoker fronts the floor space covered is 585 sq.ft., or 0.59 sq.ft. per horsepower. From the boiler-room floor to the center of the cross-drum the height is 26 ft. 6 in., and 42 ft. from the floor to the top of the economizer.

A very interesting feature is the stoker installation. Two chain grates are placed side by side in a common furnace, each being 8 ft. wide, 14 ft. 6 in. long and containing 116 sq.ft. of active grate area. Double this area bears a ratio to the steam-making surface in the boiler of 1 to 43. The stokers are motor-driven through reduction gears and belt, with vertical engines in reserve. The general design of the setting and the positions of the economizer and induced-draft motor-driven fan are shown in Fig. 3. Rising 65 ft. above the fan, or 125 ft. above the grate, is an individual self-supporting steel stack of 7 ft. diameter. Owing to the low temperature of the flue gases leaving the economizer (probably 350 deg. F.), the stack is unlined, an asphaltic paint on the interior surface protecting the metal.

Being the first of its kind in this country, the economizer is of special interest. The construction is similar to that of a B. & W. type boiler without the drum. The headers are of wrought steel and the tubes, which are 4 in. diameter and 16 ft. long, of drawn steel $\frac{1}{4}$ in. thick. As low temperatures are expected, the tubes are galvanized inside and out to guard against corrosion. The economizer is vertically baffled for three passes, the gases from the boiler entering at the front and from the third pass rising vertically through the induced-draft fan to the stack. The fan has capacity to handle 75,000 cu.ft. per min. of gas at 350 deg. F. At this rating the power required is 94 hp. To give plenty of reserve capacity for contingencies and to reduce upkeep to a minimum, a 150-hp. motor was installed. In general this policy of using motors of liberal capacity for the work has been adopted all through the station. Water to the economizer enters at the bottom of the rear header and passes through 396 four-inch tubes to leave at the top of the front heater. The relative flow of gas and water is thus counter-current.

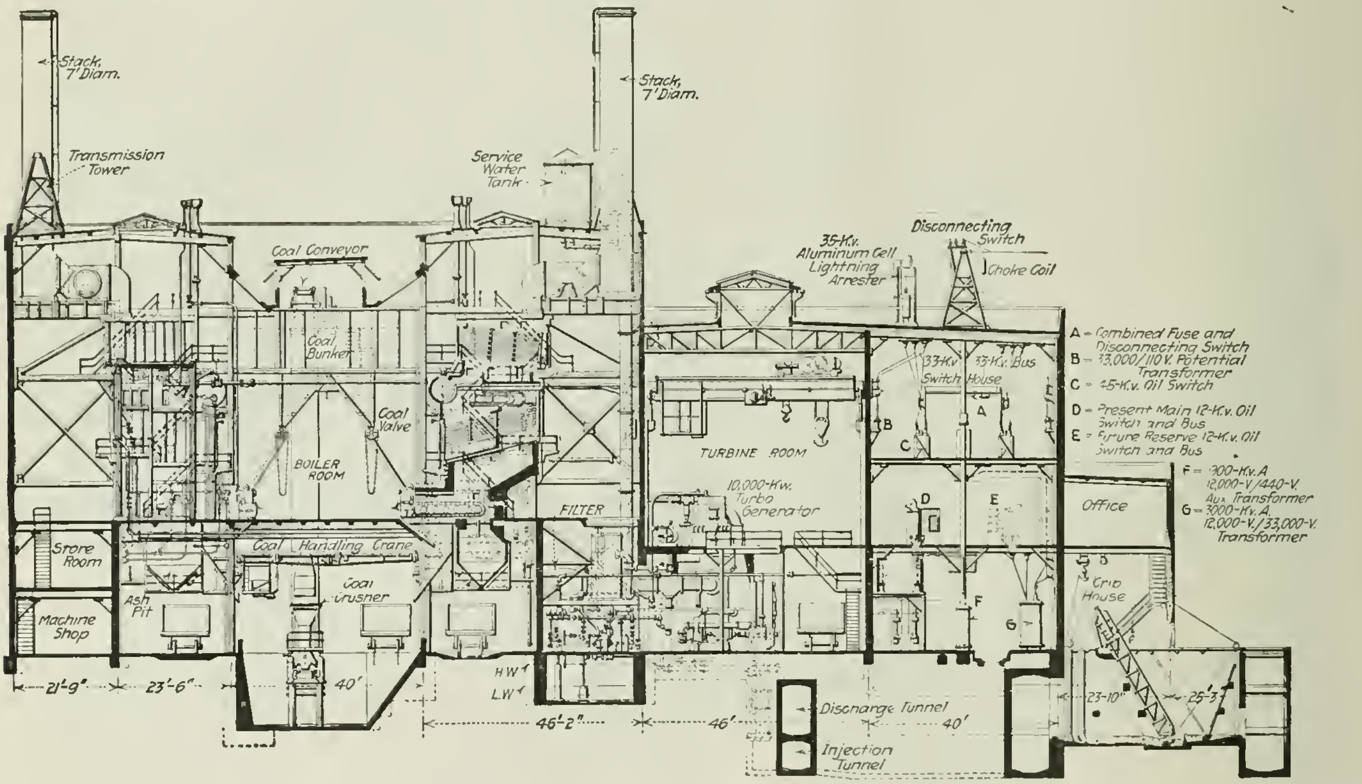

FIG. 3 SECTIONAL ELEVATION THROUGH PLANT

Reviewing the foregoing data, it will be seen that each 1000 sq.ft. of boiler-heating surface has 23.4 sq.ft. of grate, 313 sq.ft. of superheating surface, 678 sq.ft. of economizer and 3.88 sq.ft. of stack.

Feed water for the boilers is mainly condensate which has been delivered through a preheater at the top of the condenser, containing 1000 sq.ft. of surface to the heater by either one of two motor-driven condensate pumps, the duplication tending to insure continuity of service. The heater is of the open type, having capacity to serve the two boilers of the unit. Either of two four-stage turbine-driven centrifugal pumps designed

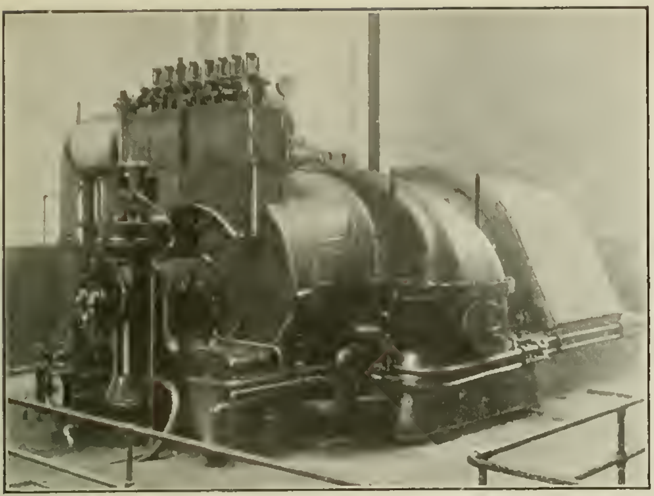

FIG. 4. TURBO-GENERATOR NOW IN OPERATION

to deliver 300 gal. per min. against a head of 375 to 400 lb., feeds the water to the boilers. The turbines are rated at 126 hp. and operate under full boiler pressure, their output being controlled by pressure-regulating valves. The water passes through the economizer and enters the boiler at both ends of the cross-drum.

The makeup water comes from a fresh-water reservoir which collects the steam-header drips, heater over flow and other other available condensation. Under float control it is also supplied with filtered service water. The house-service water supply is drawn from the condenser intake tunnel by two 600-gal. pumps, one driven by a turbine and the other by a motor. It is delivered to a service tank on the roof. From the pump discharge line several taps are taken off for transformer cooling and for various services where raw water can be used. Return water from the tank passes through duplicate pressure filters, each of which has capacity to filter 150 gal. per min. Upon leaving the filter the water supply divides, part going to cool bearings and to the lavatory system, and the balance as needed to the hot-water reservoir. The vacuum on the main unit is utilized to draw the makeup water from the reservoir into the condenser, the amount being regulated by a float in the heater. It is removed by the condensate pump in the usual way and delivered to the heater.

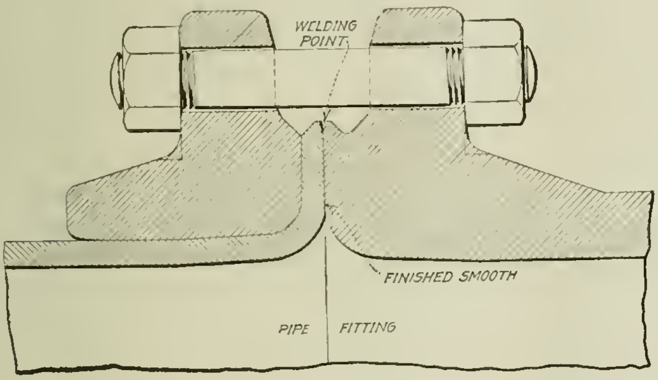

FIG. 5. CONSTRUCTION OF SPECIAL WELDED JOINT

With the exhaust steam available the water temperature in the heater under average load conditions will probably range from 100 to 120 deg. F. To maintain the temperature within this range a bleeder connection under thermostatic control has been made to the fourth stage of the turbine.

Coal for the plant, Illinois lump and screenings, is brought in over the company's siding from the Chicago & Alton tracks at Plaines, about three-quarters of a mile distant. The company has its own locomotive and coal cars and at the plant a yard containing five tracks. No. 1 is a storage track running past the south side of the building, Nos. 2 and 4 are ash tracks serving the two rows of boilers, No. 3 is the coal track, and No. 5 serves the turbine room. Between these tracks there is space to store about 10,000 tons of coal. Track No. 3, centering on the firing aisle, leads into the boiler-room basement over a concrete pit capable of storing 800 tons of coal. By a four-motor traveling crane with a 2-yd. grab bucket the coal is unloaded into a four-roll traveling crusher, driven by a 50-hp. induction motor, which discharges to a bucket conveyor delivering into the overhead bunker. The latter has capacity to hold 450 tons, or 112 tons per boiler. The bunker is made up of steel plates, concrete lined, and is divided up into four compartments with double chutes from each leading to the two stokers under their respective boiler.

Screenings are handled in the same way with the exception that the rolls of the crusher are spread to allow the coal to pass through to the conveyor. On both sides of the crusher are bypass chutes to the storage pit. The coal may be unloaded into the pit or into the outdoor storage space. In the latter case a locomotive crane unloads the coal and loads it again when it is desired to remove it to the plant.

Under each boiler furnace are ash and fine-coal hoppers. The former is brick lined and is equipped with a sprinkling system to wet down the ashes. Through a sliding gate operated by a handwheel, the ashes are passed directly to railway cars, thus obviating the need of ash-handling apparatus, always hard to maintain. Farther forward, under the stoker, is the fine-coal hopper, which delivers its contents to the con-

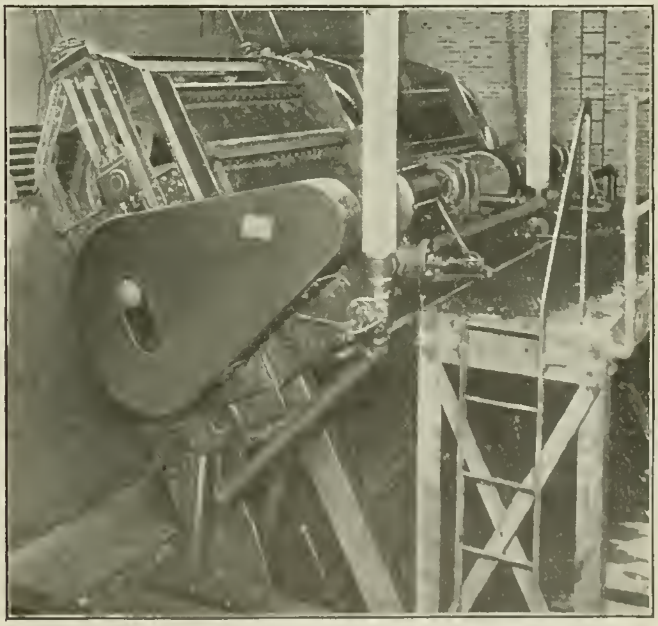

FIG. 6. TRAVELING SCREENS FOR COOLING-WATER INTAKE

crete storage pit. The outlet is controlled by a sliding gate operated from the boiler-room floor.

As previously explained, all high-pressure piping is extra-heavy, with fittings of cast or forged steel. On pipes above 4 in. diameter the special-welded joint shown in Fig. 5, is used. The pipe is extended through the flange and is belled out to form the face of the joint. The face is finished smooth, and the edge beveled off to form a V-shaped groove to receive the welding metal. On fittings a facing boss of extra thickness to form a welding surface similar to that on the pipe flange is provided. The weld is intended only to seal the joint, the bolts through the flange taking the stress. In the plan view, Fig. 2, the numerous bends in the piping to care for expansion may be noticed. From each end of the superheater there is a steam outlet, the leads from the superheater being joined by special steel manifolds at the boiler-room wall. Two boilers per turbine will be provided, but there are cross-connections between the two units so that three boilers may be used to carry the two 10,000-kw. machines. The fourth boiler provides a reserve needed at times of cleaning or inspection.

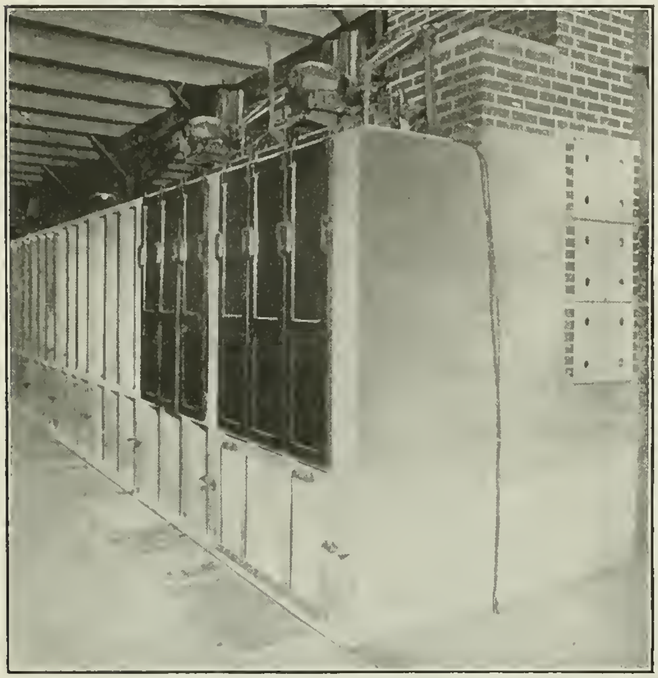

FIG. 7. OIL SWITCHES AND BUS COMPARTMENT

The main generating units of the present installation are rated at 10,000 kw. at 80 per cent. power factor. One of these is shown in Fig. 4. At the turbine the working pressure is 300-lb. gage. The speed is 1800 r.p.m. The generators are three-phase 60-cycle machines delivering current at 12,000 volts, which is standard in the company's newer plants. In the electrical end of the plant no radical departures from standard practice have been made. Distribution will be at 12,000 and 33,000 volts. A double bus system is employed throughout the station. Each generator may feed through either of two oil switches to a set of sectionalized 12,000-volt double busses. From these busses two kinds of leads are taken off; one class being the 12,000-volt feeders and the other leading to the low-tension side of water-cooled transformers, stepping up the voltage to 33,000. Fig. 7 shows oil switches and the bus compartment.

Control of all electrical equipment except auxiliary power is effected from an operating room in the switch-house located on the turbine-room floor and separated from it by a glass partition. Generator control is centered in a benchboard, and outgoing feeders are controlled by vertical boards arranged with the bench-board in the form of a hollow square. Auxiliary 440-volt power has remote mechanical control from a vertical board in the turbine room. The generator circuits are equipped with overload relays, ordinarily connected in circuit only during synchronizing, and each outgoing line has a polyphase watt-hour meter. Of the latter liberal use has been made throughout the station. Excitation is effected by 100-kw. 250-volt shunt-wound exciters mounted on the generator shafts and a 100-kw. turbine-driven reserve exciter.

Over all the main unit is 33 ft. 6 in. long and 13 ft. 3 in. wide, requiring a floor space of 444 sq.ft., or 0.0444 sq.ft. per kilowatt of rating. The height of the unit is 12 ft. above the floor line. The turbine is served by a two-pass condenser containing in 3600 one-inch tubes 20,000 sq.ft. of surface. From the foregoing figures there is 2 sq.ft. of surface per kilowatt of generating rating.

Circulating water is supplied by a centrifugal pump having capacity to deliver 18,000 gal. per min. In conjunction with the Leblanc air pump it is driven by a 200-hp. slip-ring induction motor. Duplicate condensate pumps are used, each rated to care for 360 gal. of condensate per minute and driven by a 25-hp. motor.

Cooling water for the condensers is drawn from the Des Plaines River through a concrete tunnel, the intake being 570 ft. distant from the center line of the tunnel in the turbine room. In its course to the plant the tunnel passes under the Santa Fe tracks to the screenhouse, its dimensions to the river side of the railway being 10 ft. wide by 8 ft. high. From this point on to the plant it is 8 x 8 ft. in section. Water from the tunnel enters the forebay in the screenhouse, Fig. 6, where it first passes through an iron grid of ¼ x 4-in. bars designed to keep back driftwood which may have escaped the log boom at the intake. Revolving screens are then encountered, which measure 26 ft. 9 in. between centers of the driving sprockets and 5 ft. 2 in. wide between roller centers. Through reduction gearing each screen is driven by a 5-hp. induction motor. Provision is made to swing the screens to a horizontal position for inspection or repairs. Cleaning is done during operation. Water from slotted pipes is forced at high velocity through the mesh, discharging against splashboards and draining down into a trough leading to the discharge tunnel.

Back of the traveling screens are double sets of stationary screens having ½-in. mesh to catch fibrous material, small fish or débris of any character remaining in the water. These screens are made up in sections 5 ft. 10 in. wide by 4 ft. 6 in. high. For cleaning they are removed by a hand-operated beam trolley. The discharge tunnel, 8 x 8 ft. in section, travels on top of the injection tunnel as far as the river side of the railway. Here it turns downstream and discharges into a swampy tract bordering on the river. At the turn a 2-ft. 8-in. by 3-ft. 8-in. tunnel leads from the main discharge to the intake, where during the winter season the warm water will keep down the ice. A sluice-gate valve determines the amount of water drawn off for this purpose.

Safety of the employees and congenial surroundings were features given special prominence in the design of the station. The engineer has a large roomy office, shower baths and locker rooms were provided for the help and excellent drinking water is piped from a near-by spring. In addition to the usual equipment, the station contains a machine shop, storeroom and a fuel engineer's office in which coal, the big factor in power-plant operation, will receive close attention. The station was designed by Sargent & Lundy, consulting engineers, and Von Holst & Fyfe were employed as architects. Of the operating company Samuel Insull is president; F. J. Baker, vice president in charge of operation and construction; George H. Lukes, general superintendent, and J. L. Hecht, mechanical engineer.

IMPORTANT DATA OF JOLIET STATION

Boiler Room

Type of boiler	B. & W. cross-drum water-tube
Setting	Masonry and steel casing
Number now installed	3
Steam-making surface, sq.ft	9,919
Steam-making surface installed per kw., sq.ft	2
Pressure for which boilers are designed, lb. per sq.in	350
Operating pressure, lb. per sq.in	325
Superheat, deg. F	225
Steam temperature, deg. F	650
Number of boilers per unit	2
Number of tubes per boiler	429
Length of tubes, ft	20
Diameter of tubes, in	4
Length of drum, ft.-in	23–10
Diameter of drum, ft	5
Stokers per boiler	2
Type of stoker	B. & W. chain-grate
Active area of two stokers, sq.ft	232
Ratio grate area to boiler-heating surface	1 to 43
Superheater surface (B. & W.), sq.ft	3,100
Floor space occupied by boiler, sq ft	468
Floor space per 10 sq.ft. heating surface	0 472
Floor space by boiler and stoker	585
Floor space per 10 sq.ft. of heating surface	0 59
Height of boiler from floor to center line of drum, ft	26.5
Height of boiler from floor to top of economizer, ft	42
Capacity boiler, normal, lb. steam per hr	60,000
Capacity boiler, maximum, lb. steam per hr	94,000
Per 1,000 sq.ft. boiler-heating surface:	
Connected grate area, sq ft	23 4
Stack area, sq.ft	3 88
Economizer surface, sq.ft	678
Superheating surface, sq.ft	313
Economizer	All-steel B. & W. horizontal
Number of economizers	One per boiler
Number of tubes	396
Length of tubes, ft	16
Diameter of tubes, in	4
Economizer surface, sq.ft	6,730
Induced-draft fan	Sturtevant multivane
Capacity of fan, cu.ft. gas per min	75,000
Horsepower of motor	150
Stack	Unlined steel, one per boiler
Stack diameter, ft	7
Height stack above fan, ft	65
Height stack above grate, ft	125
Coal	Illinois run-of-mine and screenings
Coal bunker	Steel, concrete lined
Capacity bunker, tons	450
Concrete pit storage, tons	800
Yard storage, tons	10,000
Locomotive crane	Browning
Traveling crane	Whiting, 2-yd. bucket, 150 tons per hour
Traveling crusher	Orton & Steinbrenner
Crusher capacity, tons per hour	125
Coal conveyor	Link-Belt continuous-bucket
Conveyor capacity at 45 ft. per min., tons per hour	120
Boiler-feed pumps	Worthington 4-stage, 3-in. centrifugal
Number of pumps	Two per unit
Horsepower of turbine drive	126
Pump capacity, gal. per min	300
Pump speed, r.p.m	2,550
Feed-water heater	Warren Webster open type
Heater capacity, lb. per hour	150,000
Number of heaters	One per unit
Pressure filters	2 per unit, New York "Jewel"
Capacity each filter, gal. per min	150
Service pumps, two, one turbine, one motor-driven, gal. per min., each	600

Turbines

Maker	General Electric Co.
Type	Horizontal Curtis
Capacity, kw	10,000
R.p.m	1,800
Steam pressure, lb. gage	300
Superheat, deg. F	225
Floor space covered by unit, sq.ft	444
Floor space per kilowatt, sq.ft	0 0444

Condenser

Maker	Westinghouse
Number of tubes	3,600
Size of tubes, in. O.D	1
Surface in condensers, sq ft	20,000
Surface per kw. gen. rating, sq.ft	2
Preheater top of condenser, surface, sq.ft	1,000
Circulating pump	Westinghouse centrifugal
Capacity circulating pump, gal. per min	18,000
Speed, r.p.m	690
Drive, induction-motor, hp	200
Air pump	Leblanc, driven by circ. pump motor
Condensate pumps	Motor-driven centrifugal
Number	2 per condenser
Capacity, gal. per min	360
Motor drive, hp	25
Screens	2 sets stationary and 2 traveling per unit
Traveling screens	Link-Belt Co.
Length, c. to c. of driving sprockets, ft.-in	26–9
Width c. to c. of rollers, ft.-in	5–2¼
Drive, G.E. induction motor, hp	5

Generator

Maker	General Electric Co.
Capacity, 80 per cent. power factor, kw	10,000
Voltage	12,000
Cycles	60
Phases	3
Field poles	4
Speed, r.p.m	1,800
Exciter mounted on shaft	100 kw., 250 volt
Exciter, turbine-driven, reserve unit, kw	100
Crane, turbine room, Whiting, tons	75

Electrical

Oil switch equipment, 12,000 volt	General Electric
Oil switch equipment, 33,000 volt	Westinghouse
Switchboard	Westinghouse
Lightning arresters	General Electric

Size of Neutral Wire for a Three-Wire System

BY T. A. NASH

While it is the practice in some localities to invariably make the neutral of a three-wire system the same cross-sectional area as the outside wires, this procedure is not always followed. Where there is likely at periods to be excessive unbalance on the three-wire system—that is, where practically all the load will come on one side of the system with no load on the other side—the neutral wire then carries the same current as the outside wire. Hence if the condition just outlined is likely to occur, the neutral wire should be made the same size as either one of the outside wires.

Some engineers specify that where outside wires are No. 6 or smaller, the neutral wire shall be of the same cross-sectional area as the outside wires, but when the outside wires are larger than No. 6, the neutral may have two-thirds of the cross-sectional area of either of the outside wires. In some cases it is permissible to make the cross-sectional area of the neutral one-half that of either of the outside wires.

Obviously, when the neutral is of smaller cross-sectional area than the outside wires, it must be protected by a fuse of correspondingly small capacity, in which case if the unbalance of the load on the two sides of the circuit becomes excessive, the fuse is likely to melt and thereby all the lights, assuming that the load is all on one side of the circuit, will be extinguished. It is for this reason that some engineers adhere to the practice of specifying the neutral of the same cross-sectional area as the outside wires. There is no reason, however, why the neutral, provided it is properly fused, should not be smaller than the outside conductors.

One of the tendencies of today is to overdo the stop-watch and the watch-dog method. Efficiency of product does not lie in that direction. It is not right to imagine that the men have no other interest in the success of the work than to watch the hands of the clock go round.

Heavy-Duty, Diesel-Type Oil Engines for Marine Work

The McIntosh & Seymour Corp., of Auburn, N. Y., has built a number of 500-hp. heavy-duty, marine-type Diesel oil engines, for use on the Pacific Coast, one of which is shown in the illustrations. The engine has six cylinders and is of the four-cycle type, single-acting and is directly reversible.

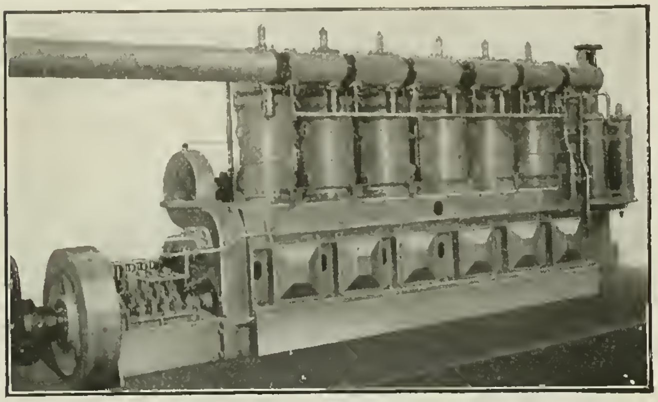

FIG. 1. ASSEMBLY OF ENGINE SHOWING CYLINDERS AND OVERHUNG FLYWHEEL

The air for atomizing the fuel for the working cylinders, also that required for maneuvering, is furnished by a three-stage compressor located at the forward end of the engine and directly driven from the engine. The compressor is built with intercoolers and aftercoolers. The valves and cages are all accessible and removable as a unit, making their removal and renewal a simple matter.

The thrust bearing, which may be of either the standard horseshoe-marine or Kingsbury type, is carried in a base bolted securely and doweled to the engine base, and contains a large bearing at its after end, making it possible to carry the flywheel overhung, as indicated in Fig. 1. The main working cylinders are bolted to the top of the engine frame and are of a simple design provided with removable liners. The heads are separate from the cylinders, each containing an inlet, an exhaust, a fuel and a starting valve. The gear for operating these valves is clearly shown in Fig. 2.

The camshaft, as can readily be seen, is carried in the housing bolted to the engine frame, and is driven by spur gears from the end of the crankshaft. From the forward end of the crankshaft a fuel pump and speed-limiting governor are driven.

The maneuvering gear, as can be seen, is at the forward end of the engine. The maneuvering is done in the proper sequence due to the interlocking feature of this device, thereby preventing the operator from damaging the equipment through a misunderstanding of its functions. The supply of oil, and consequently the control of the ship, is accomplished by one single lever. There is arranged a control lever within easy reach of the operator, which is devised to relieve the cylinder of any pressure, and when brought into operation, it automatically shuts off the atomizing air when the release valves are open.

The lubrication for the working cylinders, piston pins and compressor is effected by the use of a Richardson-Phenix force-feed lubricator driven by gears and suitably timed, so that the lubricating oil is delivered to the various parts during that portion of the cycle that is most beneficial. The oil for the crankpins, main bearings and other journals is supplied from a gravity system through gang oilers conveniently located. As the engine is entirely inclosed, the base having a bottom casting, the oil is all collected in the base from where it is pumped through a filter and then returned by gravity to the bearings. A small pump driven from the camshaft is arranged to automatically handle the oil and return it to the system.

The cooling system of this engine is so arranged that salt water can be used for cooling purposes without coming in contact with the steel studs or any part likely to be affected by it. It has the same effective cooling, however, as on stationary engines and the same even flow and proper circulation through the cylinder heads.

The average time consumed from full-speed ahead to full-speed astern for fifty maneuvers was eight seconds. Very likely this time can be somewhat reduced when the engines have become fairly limbered up and the operators are perfectly skilled in handling the equipment.

The fuel consumption of these engines is slightly over 0.4 lb. of fuel oil per horsepower-hour when operated at rated speed and load. It has been demonstrated that these engines are capable of a reduction in speed of 60 per cent. The air tanks supplied with the engine, which carry 300-lb. pressure, are of sufficient size to start the engine 44 times, the minimum starting pressure being 80 lb.

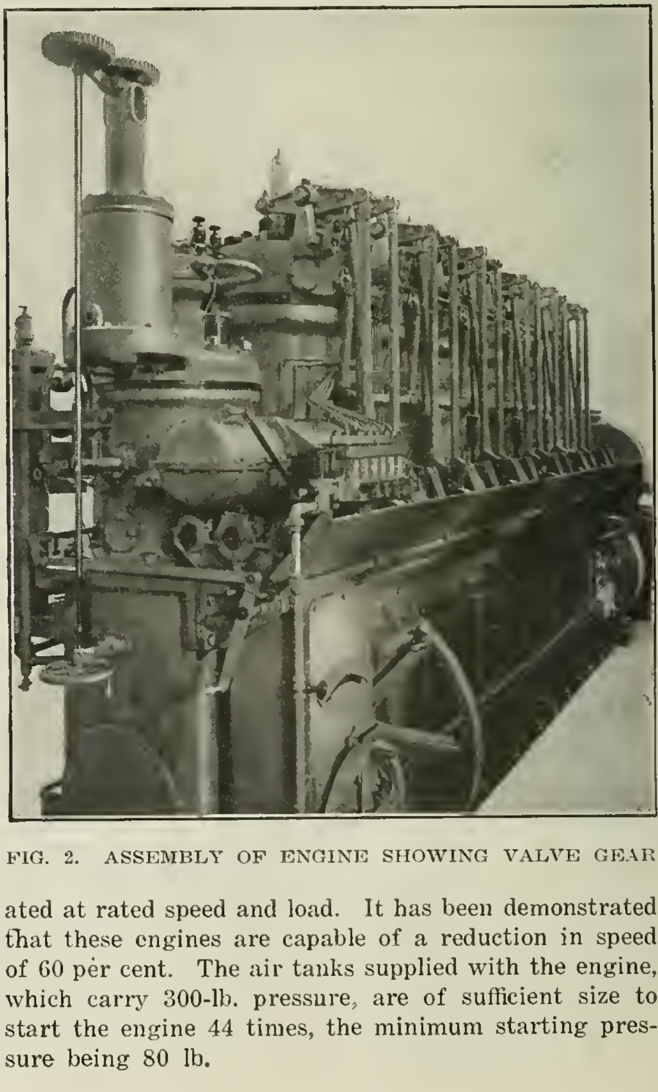

FIG. 2. ASSEMBLY OF ENGINE SHOWING VALVE GEAR

Fuel Consumption Control by the Government

By J. W. HENDERSON
Chief, Bureau Smoke Regulation, Pittsburgh, Penn.

The author proposes that the Federal Government assume absolute control not only of coal and its distribution, but of its consumption so as to conserve the supply. He believes the stoker should be adopted by most plants that the lower grades of coal may be burned. The Fuel Administration should be continued after the war, and the Bureau of Mines act as engineer for it. Specific cases of saving by better combustion methods are cited.

THE materials embraced by the term "Fuel" in this article are: Coal and its byproducts; wood and its distillates; oil; gas. The possible savings are conservatively estimated at $1,000,000,000 annually. The purpose is to offer evidence and argument in support of a recommendation that the Federal Government extend its work of conservation to include fuel consumption control and smoke regulation, and to suggest how this may be done. The proposition is that the Government shall go one step farther than is the case at present. It now regulates the production, distribution and price of fuel. There is equal or greater necessity for regulation of the methods of consumption.

The results of this work under Governmental control will be such as to (1) save fuel and (2) release men from nonproductive labor for productive effort; (3) increase the number of men available for war activities without interference with production in the industries; (4) increase the available freight-car tonnage without adding to the number of cars; (5) establish standards for fuel usage according to quality and applicability; (6) develop the coal-tar and other byproduct industries; (7) provide gas to replace the natural-gas shortage; (8) add to the supply of fuel for internal-combustion engines; (9) promote the production of fruits and vegetables; (10) protect the material welfare of the people; (11) conserve the health of the people.

All these things are possible and their attainment practicable and within the sphere of the powers of the Federal Government. In fact, no other authority in this country is available for undertaking this task with the consistency and permanency called for by the conditions. This is true in peace times as well as during the war. The reader's attention is called to quotations from a recent opinion of a Supreme Court Justice and a message to Congress of a former President as follows:

The Adamson Case, Wilson vs. New: Justice McKenna, concurring, "And submission to regulation is the condition which attaches to one who enters into or accepts employment in a business in which the public has an interest."

Special Message of President Roosevelt, Jan. 22, 1909: "The conservation of our resources is the fundamental question before this nation, and that our first and greatest task is to set our house in order and begin to live within our means. I do urge, where the facts are known, where the public interest is clear, that neither indifference and inertia, nor adverse private interests, shall be allowed to stand in the way of the public good. The freedom of the individual should be limited only by the present and future rights, interests and needs of the other individuals who make up the community. When necessary, the private right must yield, under due process of law and with proper compensation, to the welfare of the commonwealth. All this is simply good common sense. The underlying principle of conservation has been described as the application of common sense to common problems for the common good."

At this time not only the success of the war, but also the "permanent welfare of the people," is at stake. The "facts are known"; the "public interest is clear"; "adverse private interests" are ready and willing to yield to the necessities created by the war in which the country is involved; there is an awakened public consciousness to the need of conservation, and there is at hand the machinery of government capable of accomplishing the results outlined in the eleven items mentioned above.

1. SAVE FUEL

There are a number of ways in which fuel saving can be promoted. Upon the extent of fuel-consumption control and smoke regulation and the methods employed, will depend the accomplishing of the other items in the list of results. The work can be started immediately by compelling temporary changes to furnaces, pending further changes of fuel and equipment for permanent efficiency.

Emission of black smoke from stacks is a sure indication of waste. Prohibiting this smoke will result in proper firing methods, which alone will reduce the waste of fuel. The demand should be to stop hand-firing of boiler furnaces and other furnaces where capacity is beyond one-man-power. Mechanical appliances should be ordered at once, especially where the waste of fuel is most flagrant. Some governmental authority should also insist upon their proper use.

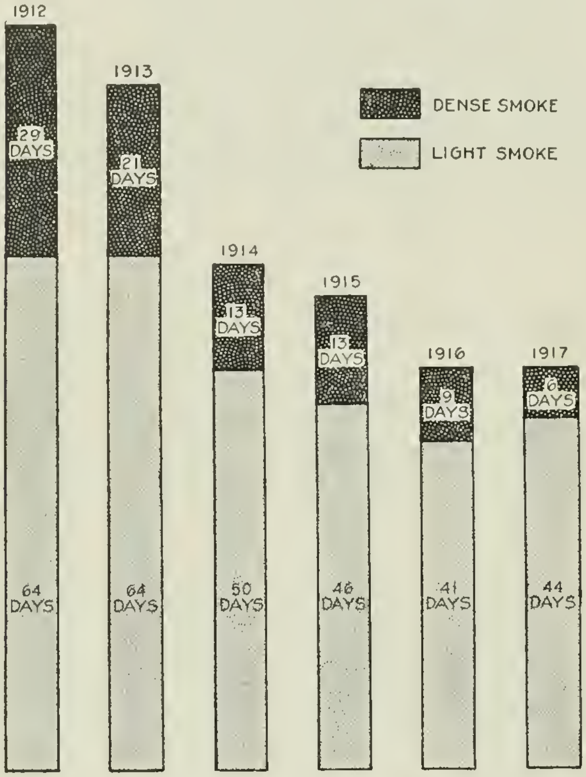
Smoke regulation and fuel-consumption control cannot be separated. Properly conducted, both lead to conservation in its broadest sense. A wider application of the term "smoke" would include zinc dust, ore dust and other destructive and wasteful materials now being emitted from stacks country-wide.

A mandate from the proper Government source having absolute power of control can cut the waste as indicated by "smoke" fully 50 per cent. almost immediately. This is a safe assertion because it merely requires personal attention with more frequent firing of small quantities of fuel to secure this result. Later, this dependence upon the man can be minimized by mechanical means with still greater economies and an increase of output from furnaces and mills.

Laboring men and their organizations need not fear the displacement of labor by mechanical appliances; first, because the great war is causing a shortage of labor and, second, following the recommendations outlined in this paper will mean raising the standard of laboring men and training them along lines that will mean increased rates of wages.

Proof of these claims will be found in the experiences referred to later where specific cases are cited showing only partially what has been accomplished and what may be expected under the plan herein proposed.

Some of the more important things that can be done almost at the outset, to save fuel by mandate of the Government in control of fuel consumption, are as follows:



SMOKE-ABATEMENT PROGRESS IN PITTSBURGH

a. Use bone coal in place of commercial bituminous and anthracite coals. This will be equivalent to increasing the visible coal supply by bringing into the market the millions of tons of bone coal piled nearly mountain high in the mining districts.

b. Use anthracite culm to replace commercial anthracite or bituminous coals. Remarks under (a) apply here.

c. Use coke breeze under boiler furnaces, thus applying what has heretofore been considered only fit for yard filling around manufacturing plants. A further saving of standard commercial coal.

Note: There are stokers now on the market and applied to furnaces efficiently burning these fuels.

d. Secure more complete combustion of all fuel, thus stopping waste in the processes of consumption.

Note: Examples are cited among the cases listed on another page.

e. Restrict the production of beehive coke, replacing it with byproduct coke.

f. Compel the application of waste-heat boilers to openhearth and other large furnaces.

g. Establish standards for fuel usage as outlined later.

h. Promote the development and use of substitutes for coal, coke and oil.

i. Maintain the gas supply for private residences where coal cannot be burned economically.

j. Increase the supply of fuel for internal-combustion engines. This may be accomplished as stated later.

k. Reduce the demand for artificial light by adoption of the daylight-saving plan, which has proven successful in Europe and as proposed to Congress by the Chamber of Commerce of the United States.

RESULTS NO. 2 AND NO. 3

Release men from nonproductive labor for productive effort, or increase the number of men available for war activities without interfering with production in the industries.

Hand-firing of furnaces is generally considered nonproductive labor. There are many cases where the application of mechanical devices for doing such work not only accomplishes fuel saving and increased output of better product, but does away with keeping men at such employment. These results will be further promoted by other labor-saving equipment such as installing ash-handling appliances in connection with furnaces now requiring several men for this work.

Instances are mentioned among the list of cases cited later in this paper. Most of them have been the result of an effort to comply with the laws regulating the production and emission of smoke from stacks. Under Government control of fuel consumption and of smoke regulation, the results can be multiplied almost immediately and continuously and kept up to whatever standard may be set by the Government.

4. INCREASE THE AVAILABLE FREIGHT-CAR TONNAGE WITHOUT ADDING TO THE NUMBER OF CARS

This will be brought about by reducing the quantity of coal required in the industries, for the same or greater output, and thereby relieve the railroads from the necessity of furnishing the equivalent tonnage for coal transportation.

A quotation on another page gives a concise statement of this phase of the problem.

5. ESTABLISH STANDARDS FOR FUEL USAGE ACCORDING TO QUALITY AND APPLICABILITY

This heading carries its own argument. The country might be divided into fuel zones. Anthracite coal and natural gas should be saved to the people for use in the homes. Anthracite coal should not be permitted as fuel for boiler or other furnaces wherever other fuel, except natural gas, is available at the same cost or less, per unit of output. Such requirement might also be applied to the gas from byproduct coke ovens.

Low-volatile bituminous coals should be conserved for special uses where other bituminous coals cannot be used without excessive smoke, but where for other reasons, such as furnace construction, bituminous coals are the logical fuel. These include locomotives at terminals and in switching service, vertical and stationary boilers of the locomotive type.

It just happens that the experience with low-volatile bituminous coal in locomotive practice has been found more economical in the way of fuel saving for the same service, as compared with high-volatile bituminous coal.

6. Develop the Coal-Tar and Other Byproduct Industries

Here is opportunity for launching new industries which need fostering in this country. These industries are directly related not only to fuel saving, but also to all the results enumerated in the first part of this paper. If restrictions are placed upon the waste of coal in coke production, the industries incidental to the byproduct-coke processes will be placed on a footing to compete with foreign countries.

The coal tar that will be recovered from byproduct coke making and wood distillation can be used as a substitute for coal, oil and gas, in many types of furnaces. A wide range of products may be produced by these processes, among which may be mentioned gas, paraffin, tar, resin, benzol, creosote, ammonium sulphate, alcohol, charcoal, pyroligneous acid, toluol.

As an example of how these products run into values in dollars and cents, figure on the possibilities in regard to gas from byproduct coke. Available statistics show coke produced during 1916, in the following amounts, in tons: Total coke, 51,544,447; beehive coke, 35,464,224; byproduct coke, 16,080,223. Allowing 8000 cu.ft. of gas per ton of coke produced, if the beehive coke had been made by the byproduct process, it would have amounted to 283,713,792,000 cu.ft. of gas. On the basis of one-half the heat value of natural gas, this is equivalent to 141,856,896,000 cu.ft. The commercial value figured on the consumers' rate (net) for natural gas in the United States is: 141,856,896,000 × 28.63c. per 1000 cu.ft. = $40,613,629.

Reference is made merely to the gas that might have been recovered should the quantity of beehive-oven coke have been made in byproduct ovens and without considering the gas that may have resulted from the coke produced in 1916 by this latter process. The 283,713,792,000 cu.ft. of byproduct oven gas as estimated according to its equivalent heat value in terms of natural gas, and based on the natural-gas consumption in the United States, would supply the demand for residence uses to the extent of 1,420,000 homes, satisfying the needs of about 10,000,000 people.

If it were used in melting steel by the openhearth process, the output from such furnaces would be in excess of 7,000,000 tons.

So much for the gas from the source indicated. The other products are of equal value in many ways. Incidental to the proposed discarding of beehive ovens is the elimination of smoke from such ovens and its ill-effects upon health and property.

7. Provide Gas To Replace the Natural-Gas Shortage

This is one of the incidental possibilities from coke making by the byproduct process. It should not necessarily follow that all the gas recovered in coke making shall be diverted to private-residence purposes, but this may be done where such use of it will be of more value to the country than when otherwise consumed.

If the total coke production for 1916, of 51,544,447 tons, had been from byproduct ovens, the gas that might have been recovered would have been equal in heat value to about 27½ per cent. of the total quantity of natural gas consumed in the United States that year.

Byproduct ovens can be operated primarily for gas production and at the same time give a soft coke comparatively high in volatile, suitable for private-residence furnaces, and produce the valuable chemicals already mentioned.

8. Add to the Supply of Fuel for Internal-Combustion Engines

Referring to the materials resulting from byproduct coke making, it is to be noted that benzol is among the number. As to the possibilities of accomplishing the purpose mentioned here, the reader is to note the following:

> Commercial alcohol and gasoline are not miscible. Alcohol and benzol are miscible and make a most efficient fuel, and further, after the addition of benzol to alcohol, the mixture will carry a high proportion of gasoline. The future may see benzol as the tie between gasoline and alcohol, permitting a piecing out of the gasoline supply and an introduction of alcohol as a commercial motor fuel.—*Journal of the American Society of Mechanical Engineers, June, 1917, p. 497.*

As smoke and its evil effects cannot be confined within political boundary lines set up by government, and as its prevention saves fuel and labor, improves products and increases output, and for other reasons which naturally follow, smoke regulation should be in the hands of the Federal Government.

In the following, Dr. Arthur A. Hamerschlag, director, Carnegie Institute of Technology, Pittsburgh, Penn., voices the opinion of many men:

> The Government has undertaken, for the benefit of the nation, to regulate and fix the price of fuel. It has also been interested in distribution, governing the car supply and determining the volume of fuel to be shipped to various centers. But it has neglected what is an equally essential element in fuel conservation, the consumption of fuel in efficient appliances. This has been left to the individual industry and consumer. It ought to be under the supervision and control of a centralized government agency, coöperating through state and municipal agents, that would compel the elimination of waste by demanding more efficient methods of securing heat from fuel.
>
> Until the Government recognizes this element of the situation, at least 25 per cent. more fuel will have to be produced at the mines than is needed in order to develop the energy required for the service of the nation.
>
> If we could increase the car supply 25 per cent., the labor supply 25 per cent., the output from the mines 25 per cent., or reduce the price of fuel to the consumer 25 per cent., we would consider that a great economic and patriotic movement was in progress.
>
> Since it seems impossible to increase in this ratio either the labor or car supply, why not attack the problem from the other end, accomplishing an equally satisfactory result?

This brings us to the "Cases" referred to several times in the preceding pages. What has been done in most of these instances has been brought about through pressure incident to enforcing the ordinances regulating the production and emission of smoke from stacks in cities.

From a Large Steel Corporation, Pittsburgh Plant: "To do away with the smoke evil, to save labor and make the fuel consumption more effective, we have endeavored to put into use such mechanical devices as will produce the best steam economies. Here we have scrapped an old plant of 55 boilers located on valuable land leased by your company for many years, in which boilers the insurance companies would allow a pressure of but 85 lb. and have replaced them with eight 600-hp. units, having double the steam pressure of the old boilers, and with mechanical stokers. These eight boilers cost, with boiler house, coal- and ash-handling apparatus, including every mechanism known to produce an up-to-date plant, but $130,000. This new installation is saving $1500 per month in payroll and .$3500 per month in coal, equal to $60,000 per annum, or 6 per cent. on $1,000,000. In addition, it has increased the capacity of the whole mill through a greater steam supply."

An Office Building in Pittsburgh: "In the winter of 1903 we installed four stokers under four 200-hp. boilers at a cost of between $4000 and $5000, including automatic control, air piping, blower engine and blower. Our average cost of upkeep to and including December, 1914, covering all repairs and replacements in connection with the stoking system, has been 2.79 per cent. on the original cost of installation. During the fiscal year preceding the installation of our stokers, our coal consumption was 171,010 bu., while in the year following, with the same steam requirements, it was 141,901 bu., a saving of 1106 tons, or 17 per cent."

A Bank Building in Pittsburgh: "We installed stokers, and the cost of coal and labor incident therewith was $6082.53. Assuming that we would have burned gas in that year, at the new rates the cost would have been $9254.25. Comparing these figures with those of the coal consumption, we have saved $3171.72, or practically more than the cost of the stokers."

An Independent Steel Company, Pittsburgh: "The boiler plant has 17 boiler furnaces. When stokers were applied to 9 boilers, they were producing as much power as they had been getting from the 17 boilers and replaced 23 men who had been used as firemen. This installation was made during the great demand on the plant for output and within a year beginning November, 1915."

A Manufacturing Company, Ohio: "After having stokers under three 150-hp. boilers for the past twenty months, I can issue the following information from practical experience: They have reduced our fuel bill 30 per cent. and a saving of $998 on labor for one year has been noticed."

A Manufacturing Company, Buffalo, N. Y.: "The four stokers installed have given the best of satisfaction, having done better than the guarantee. The saving in coal is equal to 16 per cent., and maintenance has been only an average of 0.01½ per cent. of the investment. The operation is very satisfactory, and boiler output can be controlled to the greatest possible economy."

A Tin-Plate Company, West Virginia: "The application of stokers to hot mill furnaces shows two things: First, that the coal consumption is reduced 20 per cent. to 25 per cent. and maybe more in some instances; second, because the air necessary to burn the coal is under control this gives absolute control of the flame and heat, which in turn enables the operator to heat his iron without scale. This, we find, is a great advantage to hot mill furnace work, and unless gas is obtainable at a very low price, the stoker-fired furnaces would be much more preferable. We have, in fact, installed in another of our plants stoker-fired furnaces to replace gas-fired."

A Foundry Company, Buffalo, N. Y.: This refers to a powdered-coal installation. "We have just completed dumping the castings in our No. 4 oven, and I have never seen iron in quality and uniformity to equal it. Every piece has been perfectly annealed, and they are 25 per cent. tougher than anything we have ever had from our other furnaces equipped with the old burners. The saving in coal will be around 30 per cent. Just as soon as we have run through two more ovens under favorable conditions, I will give you the exact figures showing number of pounds of coal per ton of castings."

The case mentioned as having experienced the greatest economies has not reached its maximum in this direction. Even this case is not as exceptional as some might imagine. All those shown herein indicate the possibilities for savings in the use of coal.

What the plants were doing previous to the changes leaves no doubt as to the necessity for taking action toward more efficient operation. Further economies in this direction, and in other ways as indicated in this paper, depend upon action by the Federal Government.

Van. H. Manning places the loss last year at $500,000,000, due to inefficient use of coal. Intimate acquaintance with plant operations, as a result of being connected with the Bureau of Smoke Regulation, Pittsburgh, Penn., makes it possible to testify that Mr. Manning's total figure is a conservative one.

The Working Plan Outlined

The machinery of government at hand is in the Fuel Administration and the Bureau of Mines. The foundation is already laid. It only remains for the Fuel Administration to broaden the scope of its activities and continue its existence and aims after peace shall be declared. The function of the Bureau of Mines should be to furnish information to be used as the basis for action on the part of the Fuel Administrator.

Example: The Fuel Administrator might desire data in regard to the practices and methods of a certain concern. Upon advice to this effect, the Bureau of Mines would make a thorough survey and report the results to the Fuel Administrator for such action as the conditions might warrant. For instance, if the concern should be using, say, 1000 tons of coal a day for a given production when a competitor is using but 750 tons per day for the same amount of output, the former may be compelled to take action leading to the efficiency of the latter.

It must be conceded that everything points to the plan proposed being feasible and practical and in line with a statement of the President in an address to Congress, Apr. 8, 1913, as follows: "We must . . . put our business men and producers under the stimulation of a constant necessity to be efficient, economical and enterprising, masters of competitive supremacy, better workers and merchants than any in the world."

Attention is called to an error in the article published on page 16 of the Jan. 1, 1918, issue of *Power* wherein the title should have read Tyler Condensation Meter instead of Taylor, and the manufacturer's name should have read Tyler Underground Heating System instead of Taylor, as published.—Editor.

Fires in Turbo-Generators

By M. A. WALKER

The possibilities of fires in large turbine-driven alternating-current generators are discussed and some of the possible means of combating these fires, should they happen to start, are suggested.

IN LARGE power-stations two goals are sought—one, economy of operation; the other, reliability of service. For large turbo-generators the former is accomplished by operating them at high load factors. Reliability is obtained by first-class construction methods and ample precautions. These generators are rarely if ever tied in to the station bus by automatic circuit-breakers, but instead must be disconnected by hand. Generator reactances, may, however, be installed to limit the current from or to the individual generators. Bus-tie reactances are likewise often employed for sectionalizing busses and limiting the energy transfer from one section to another. Many generators are controlled automatically, however, by means of balanced relays, so that the generator may be automatically disconnected from the station bus when it short-circuits internally, thus isolating the machine and preventing the flow of current from the station into the machine in trouble. This is a very necessary precaution because of the enormous magnetic stresses and heating involved, due to the current delivered into the defective machine from other units on the system. The modern turbo-generator may be capable of generating a current as high as twenty times normal on short-circuit and for the first few cycles.

Combustible Materials in Turbo-Generators

It is often stated that the modern turbo-generator contains nothing that will burn or support combustion. Practice refutes this, however. The cambric insulation impregnated with varnish makes an inflammable material, combustible in still air and quick-burning in an air current, such as the cooling air passing through the turbo-generator. The various tapes and cording on the end turns are likewise inflammable. The wooden wedges and spacers are also combustible, though some makers employ fiber wedges and spacers, a practice thought inadvisable since fiber warps and shrinks and absorbs moisture and oil. Other manufacturers employ wedges of brass, which is perhaps the best practice of all. Dust and dirt become embedded in the stator windings and likewise in the rotor, in an intensely dry condition, although portions are oil and grease soaked. It is possible that when an all-mica insulation is used, with noncombustible spacers and wedges and nothing to give off inflammable gas, the turbo-generator may be claimed to be fireproof. Even where air filters and washers are employed, as they are for the largest machines, dirt and dust gradually collect and make conditions favorable for fire.

The amount of air used by turbo-generators for cooling purposes depends on the efficiency of the machine. For a unit of about 25,000 kw. an average value would be about 2.5 cu.ft. per kilowatt, or a total of around 60,000 cu.ft. per minute. As the air ducts through the core and windings are restricted, this enormous quantity of air passes through the machine at a high velocity, probably between 5000 and 10,000 ft. per minute. If, now, a flame or arc starts, it is obvious that this high-velocity air fans the flame into an intense heat, burning very much like a blow-torch, which destroys everything within its reach—copper conductors, iron laminations and everything else. This high-velocity air thus causes not only more intense damage, but likewise more extensive, instead of somewhat localized as might be expected to be the case where the air is stagnant.

Most Favorable Place for a Fire

The most favorable place for a fire to start seems to be around the end of the winding and usually close to where the coils emerge from the slots. It is here that coil movement is most likely to occur, also the dielectric strains are the greatest and the accumulation of dust and dirt finds a ready resting place.

A fire started in varnish-impregnated cambric with a rapid supply of oxygen from the air may persist for an hour or more, although voltage and current no longer exist. Apart from the amount of combustible material, its combustibility is increased by the formation of gases from the impregnating compounds employed. The difficulties of fighting the fire are very real—it is out of sight and difficult to get at. Usually the casing of the generator has become so hot before help arrives that the covers cannot be touched for removal, while smoke and the noise from within do their part to interfere. In a severe fire the generator cannot be opened until the fire has burnt itself out and the outer casing has been cooled off with water. Perhaps this is really just as well, for combustion cannot exist without air, and it is probable that the fire extinguishes itself more rapidly by being inclosed than if the burning parts were thrown open to the air.

Extinguishing Fires in Turbo-Generators

As scientific methods are employed in the design, installation, operation and maintenance of a turbo-generator, it would seem that such might well be extended to fire fighting should the emergency arrive. Flooding the interior with water in a haphazard way will probably do more harm than good. To fight a fire scientifically in the present instance, it must be fought by methods thought of before the emergency happens and not by any or all methods that suggest themselves at the time. To the writer it appears, for the same reasons advanced in the article entitled "Transformer Fires," which appeared in the issue of *Power* of Sept. 18, that no effort should be made to open the cover of the generator. To do so permits the ingress of air and the escape of the gases of combustion, which, if confined, assist in extinguishing the fire.

To extinguish a fire rapidly, safely and with a minimum of damage the following precautions appear to warrant consideration: (1) When an internal short-circuit occurs in a generator, whether between phases or from one phase to ground, the automatic control should disconnect the generator from the system and thus prevent the rush of current from the station bus into the fault. In addition to this—which is being done quite widely—the excitation of the generator should be killed simultaneously, by control from the same source as the main circuit-breakers. (2) Simultaneously with isolation of the defective generator the air supply should be shut off. The air inlet and outlets should have doors, normally open, but arranged to close by gravity, held open by a solenoid-controlled or motor-operated latch, in turn controlled by the balanced-relay protective circuit. Thus when an internal short-circuit occurs, which, as already pointed out, may be followed by a fire, not only would the generator be isolated from the system, but its voltage is killed and the supply of forced air for fanning the flame is cut off. The confinement of the gases of combustion within the machine will assist in extinguishing the fire. Should a fire start, there is less chance of its obtaining headway, while its effect should be local instead of distributed. (3) The shutting off of air is a radical and effective step toward preventing and limiting the fire. However, more heroic steps need be taken in quenching a fire once it starts. Therefore why not, as part of the installation, connect at two or more different locations of the generator casing inlets for fire-fighting fluid, so arranged that a fire in any portion of the windings can be reached? These inlets may be connected to water hydrants, storage tanks containing water, carbon tetrachloride or even carbon dioxide. The behavior and disadvantages of water are well known; it is, however, the most inexpensive. Carbon tetrachloride and carbon dioxide are both powerful fire extinguishers. They probably would smother a fire more rapidly than water, especially when used in the gaseous form. Carbon tetrachloride is an efficient solvent for rubber, which is, however, little used in modern generators, cambric and mica having taken its place. Tetrachloride is a rather rapid anæsthetic when admixed with air, while carbon dioxide is poisonous. Both these hazards should be borne in mind, although in stations where ventilation is good and the roofs high the danger is small. Where inlets are installed in the generator casing, the valves controlling them should not, as with the other safeguards, be automatic, since every short-circuit does not necessarily cause a fire, therefore does not require turning on the fire extinguisher.

OBJECTIONS TO THE DIFFERENT METHODS

There are objections to all the foregoing suggestions: An automatically closing air inlet and outlet may close accidentally and thus cause overheating by interrupting the ventilation. Killing the excitation when the machine protective circuit operates accidentally, as it sometimes does for unexplained reasons, makes for delay in placing the machine back on the system. Every complication adds to the possibility of service interruptions. All precautions cost money, and in the present case are taken against a contingency that admittedly may never occur. Perhaps the cheapest precaution and the one that is least likely to cause trouble is that of installing inlets into the generator for water or other fire-extinguishing agency.

It must be realized that when turbo-generators of 70,000 kw. come into use, with boilers and auxiliaries, an integral part of the whole, taking one out of service means a big loss in capacity and also in the station's earnings, for the interest upon the investment still goes on.

No attempt has been made to cover the matter of generator fires fully in any one respect. Rather has effort been made to show that fires may occur; that the ventilating air adds much to the havoc wrought by the fire, and may even be the only means of permitting it to persist; and possible ways of extinguishing a fire as quickly as possible. What every operating engineer should realize is that a turbo-generator is not fireproof, that a fire may start and persist with great tenacity under the influence of the ventilating air drawn in by the machine as long as it revolves. Moreover, once fully started, a fire is rarely quenched until it has burned itself out, by which time the electrical end is practically destroyed. With the increasing use of turbo-generators and with increasing capacities, this subject is becoming of more and more importance. Experience is the best teacher, but it is preferable to gain experience of this sort second-hand. It is hoped, therefore, that this article in surveying conditions as the writer has found them may tempt others to enter the discussion and thus make available their ideas and the interchange of experiences.

Adjusting Marine-Engine Bearings

By William M. McRobert

One of the most important of the many duties of a marine engineer is the adjustment of the main engine bearings. To engineers who have operated on lake or river steamers it might be said that running an engine on the ocean is a little different from operating on inland waters, for it is the practice on fresh water to allow a stream of water to flow continuously on most of the bearings to avoid overheating and to reduce the amount of lubricating oil used. This cannot be done at sea, as the salt and other solid matter in the water would ruin the bearing in a short time, so that dependence is on oil alone.

When an engineer joins a ship with which he is unfamiliar, he should, in order to avoid trouble while on a voyage, examine and adjust all the main bearings and the crank and crosshead brasses. When proceeding to adjust a bearing and before taking off the nuts, they should be marked so that their respective positions may be known and the amount, if any, taken up in adjustment determined. To make the nuts readily distinguishable, they should be typed *P* for port and *S* for starboard, together with the number of the particular bearing to which they belong. The nuts on No. 1 bearing would therefore be designated as, *P*1 *S*1, for when looking toward the bow of the vessel the side to the left is known as port and to the right is starboard.

A simple and permanent method of marking the nuts so that mistakes in adjustments are practically eliminated is shown in Fig. 1. Prior to slackening back a nut, cut an arrow on the bolt with a thin, sharp chisel and make a light mark on the nut to coincide with it. Next remove the nut to the vise and graduate off somewhat as shown, using the mark already made for the zero or starting point. A piece of wood is necessary as a center for the nut when laying off the graduations with a pair of compasses and a sharp flat chisel.

The arrow on the bolt will be used as the base from which all readings are taken, and a record of the position of each nut should be kept for reference in a manner similar to the following:

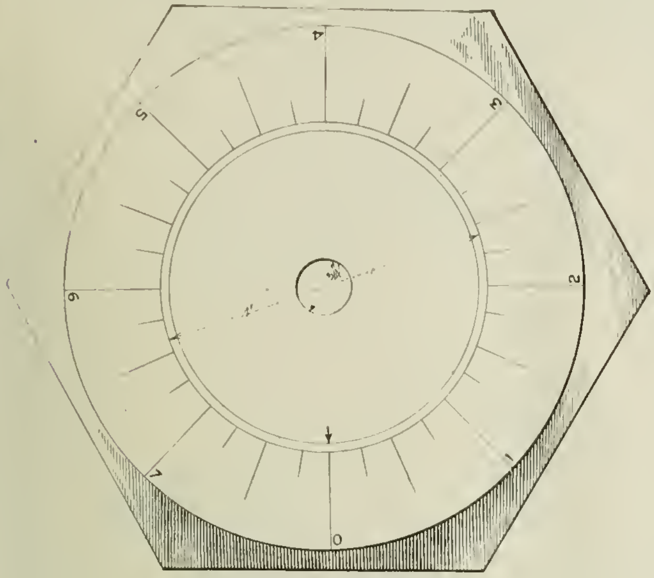


FIG. 1. NUT MARKED TO FACILITATE ADJUSTMENT

S. S At Port of Date.

MAIN BEARINGS

	Port Nuts		Starboard Nuts	
No. 1	Before Adjustment 4½	After 4¾	Before Adjustment 6¼	After 6½
No. 2	Before Adjustment 5	After 5½	Before Adjustment 2½	After 3
No. 3	Before Adjustment 6	After 6¼	Before Adjustment 3¾	After 4¼
No. 4	Before Adjustment 1½	After 1⅝	Before Adjustment 5¼	After 5⅞
No. 5	Before Adjustment 3¼	After 3¾	Before Adjustment 4½	After 5
No. 6	Before Adjustment 2½	After 2¾	Before Adjustment 6½	After 7

All bearings including the crank bearings should have the same kind of record.

Having marked and removed the nuts from the bolts on one of the main bearings, for example, the engineer lifts the cap clear of the journal, by means of a chain or rope block, then lifts off the liners, noting down their number and description so as to replace them after cleaning thoroughly. In marine work soft lead wire is generally used to ascertain the clearance between the wearing surfaces. To do this, take two pieces of wire and place one, circumferentially, on each end of the journal within two or three inches of the ends of the bearing surface. On a large engine three "leads" should be used, the additional one at the center of the bearing. Care must be taken that the wire is a little shorter than the exposed part of the shaft or the ends will get on top of the liners when the cap is put on. Making sure the leads are in their proper positions (a little soap or grease will keep them in place), lower the bearing cap, put the nuts on and tighten them simultaneously until they are at their respective marks or perhaps a little past them, until the cap is "solid" on its liners. Notice particularly whether the cap is solidly down on the liners; if not, insert an extra liner to make it so. Again mark and slack off the nuts and lift the bearing cap and gage the leads for thickness and the uniformity to which they are squeezed out. Any desired adjustments may be made by removing or adding liners as occasion demands. Next comes the connecting-rod alignment and the adjustment of crank and crosshead bearings, referring to Fig. 2.

Every steamship engine is equipped with either a steam- or hand-operated turning engine for the purpose of setting the engine in any required position to effect repairs. Prior to moving the engine, take a look over the stern of the ship to see that there are no boats or ropes near the propeller, and also be sure that the engine itself is clear of obstructions; then by means of the turning engine put the high-pressure crank on the top center. On the face of the crosshead-shoe guide will be found two tapped holes, to which a piece of plate or a casting may be attached to support the piston and connecting-rod when the rod is disconnected from its crankpin. After this "guide plate," as it is called, is securely bolted in place, attach to each side of the crosshead a differential chain block. Mark the position of the crank-bolt nuts, as in the case of the main bearings, then slacken them back after screwing an eye-bolt firmly into the threaded holes in the ends of each of the connecting-rod bolts and pulling up slightly with the two chain blocks; next lower the bottom half of the bearing gently on both tackles until it rests in the crank pit. The eye-bolts and also the hooks on the chain block are small enough to pass through the bolt holes so the lower half can be lowered into the crank pit, or in case of small engines a rope sling may be used from the eye-bolt to the hook. A rope sling is sometimes used in place of the eyebolts to support the chain blocks at the crosshead. With the turning engine, turn the crank slightly ahead until the crankpin is just clear of the top half of the bearing, first making sure that the latter is held in place with a capscrew passed through each of the flanges. Keep the bearing off the crankpin, and with a pair of inside calipers measure to see if the end of the connecting-rod is hanging central between the webs of the crank. In order to obtain smooth running, this condition must be realized.

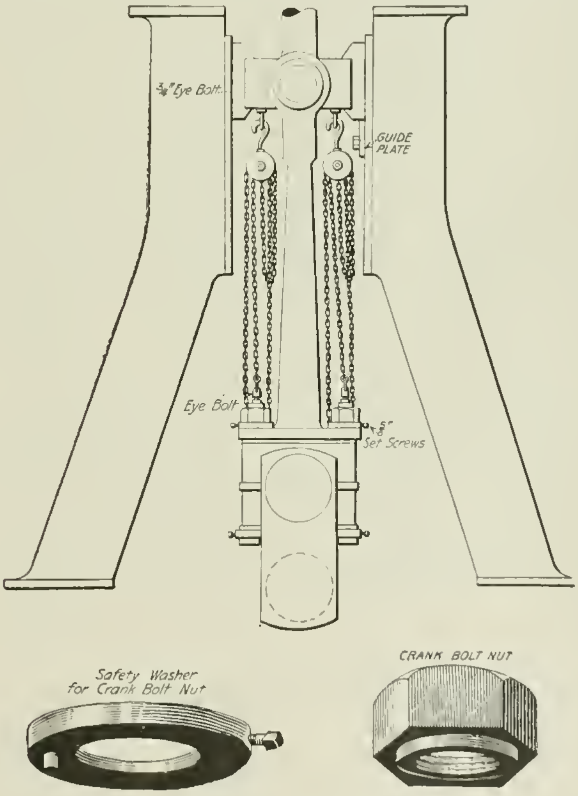

FIG. 2. UNSHIPPING A CRANKPIN BEARING

Should the connecting-rod be out of alignment, it may be corrected by inserting a thin liner between the lower crosshead brass and the top end of the connecting-rod. Pounding might be overcome in many engines if the rods were put in line. It is sometimes necessary to scrape the babbitt metal of the bearings in order to get a true alignment, but no matter what is called for, the engineer can rest assured that continual trouble will ensue as long as the conneting-rod is out of alignment.

On a 12,000-hp. quadruple-expansion engine the writer sailed with, he spent many a hard day in tropical climates scraping the bearings to put the high-pressure rod in line; in fact, on every available opportunity the chief had him on this job, but eventually success and comfort were the reward.

If the rod is found to be in line, turn the engine back until the crank is on its exact top center and take off the guide plate and remove the cap bolts from the top half of the connecting-rod bearing, then raise the lower bearing out of the crank pit until the bolts have just entered the holes, then carefully place two or three pieces of lead wire circumferentially at equal intervals along the surface as described for the main bearing, then pull the bearing or cap up into position and tighten the nuts to their previously located marks. Again slacken back the nuts and lower the bottom half of the bearing just so the leads can be removed. If they are the right thickness, clean the bearing thoroughly and pour a little clean oil on the surface, then heave up and pull the nuts solidly up to their marks, using a hammer on the wrench and being certain as before that the bearing is up solid on the liners. The intermediate-pressure and low-pressure engines are adjusted in turn in the same manner as described.

The foregoing is intended as a mere outline on the subject of the adjustment of marine-engine bearings, all of which is familiar to seagoing engineers, but there are three important points to be remembered, which should be emphasized; namely, before turning the engine, see that the propeller is clear, that the guide plate is off and that all other obstructions are removed.

Morris Improved Tube Beader

To properly expand and bead a boiler tube requires considerable experience and expertness when the common expander and beading tool are employed. An inexperienced workman is more than likely to thin the tube end by excessive rolling, as in Fig. 1, thus reducing its strength where it is needed. In beading the tube ends by the hand tool they may be bulged, as shown in Fig. 2, thus forming a pocket between the tube and the tube head, which would increase the possibility of the tube burning out at that point.

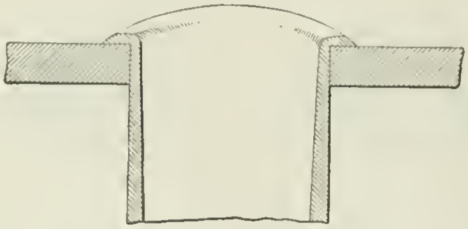

FIG. 1. RESULT OF EXCESSIVE ROLLING

A machine that has been designed to strike a blow on the beading tool at the right position and to expand and bead a boiler tube at one operation, at the same time eliminating the defective results shown in Figs. 1 and 2, has been developed by the Wallace Manufacturing Co., 1319 West 42nd St., Kansas City, Mo. This device, Fig. 3, known as the Morris beading tool, consists of a lever-operated 6-lb. hammer *A*, the striking blow of which is governed by the propelling springs *B*, the strength of which is adjustable by the bolt *C*.

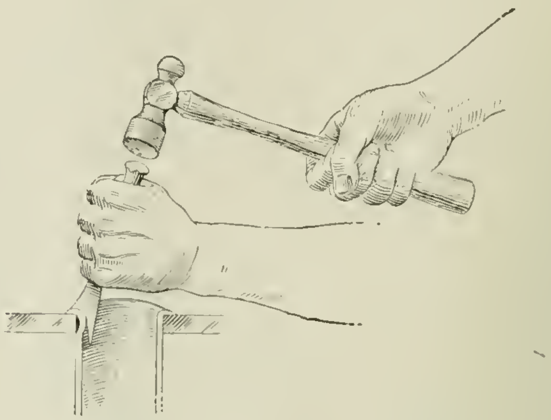

FIG. 2. BULGED TUBE IN TUBE SHEET

A beading tool *D*, which beads and expands a tube in one operation, is at one end of the frame holding the hammer. It is rotated in the tube by a ratchet movement *E* actuated by the hand lever *F* which operates a camwheel *G* which is rotated by the two pawls *H* to lift the hammer and trip it into action. The tool is held in place at a boiler head by an adjustable supporting block *I* containing wedge bolts, which are expanded after the supporting block is placed in a tube, by the bolt *J*. A head block *K* holds and guides the beading tool in place, and the dotted line *L* shows the angle the tool is driven on for expansion of the tube.

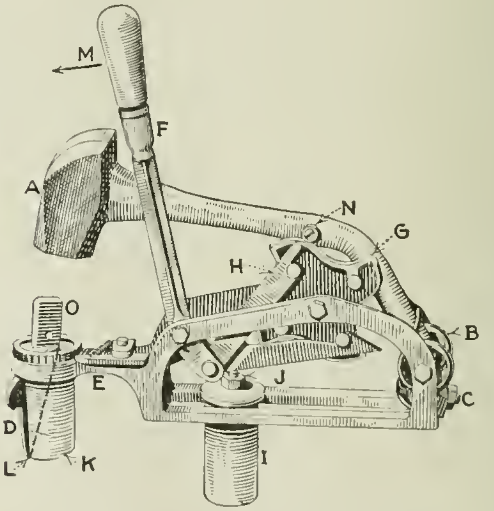

FIG. 3. MORRIS TUBE BEADER

The application and operation of the tool are simple and it can as easily be worked at one part of the tube sheet as at another. When about to use, the head block of the beading tool is placed in the tube to be secured in the tube sheet. the supporting block being placed in any other tube already in place, within the scope of the tool. With the tool in place the operator pulls or pushes the lever in the direction of the arrow *M*. This movement rotates the camwheel *G* to the right, and as the roller *N* reaches the edge of the camwheel, the weight of the hammer *A* and the tension of the springs *B* produce a sharp blow on the head block *O*. Each time the lever is operated for a hammer stroke, the ratchet is rotated two notches. Fig. 4 shows how the beader enters a tube and also the kind of joint it produces between the tube and the head, there being no thinning of the tube end or forming of a pocket between the tube and the head.

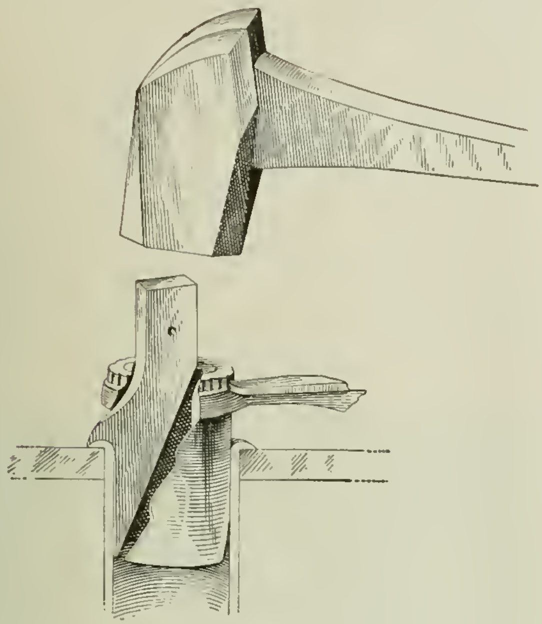

FIG. 4. HOW THE BEADER FITS IN THE TUBE

Calculating the Contents of Oil Tanks

By R. T. Strohm

The increasing use of liquid fuels has brought about the storage of large quantities of oil, gasoline and similar products. The usual type of storage tank is a cylindrical steel shell with bumped heads, placed in a horizontal position and ordinarily buried in the earth as a matter of safety. The calculation of the amount of oil in a tank of this kind, when the oil stands at a certain level, is a problem that seems to cause operating engineers considerable difficulty, largely because of the use of bumped heads. If the heads were flat, the problem would be greatly simplified.

The depth of the oil is commonly measured in inches above the bottom of the tank, this distance being determined by a measuring rod inserted through the manhole or by some form of registering gage. The known data, therefore, are the length and diameter of the cylindrical part of the tank, the radius of curvature of the heads, and the depth of oil in the tank, and from these the quantity of oil must be calculated.

Since the amount of oil on hand at any given time is information that must be quickly available whenever it is called for, the best thing the engineer can do is to make up a table showing the cubic contents of the tank for every inch of depth. Then, by measuring the depth of oil, he can quickly refer to the table and so determine the quantity of oil on hand.

If a reliable meter is available, the quickest way to compile the table is to use the arrangement shown in Fig. 1. Connect the meter *a* to the filling pipe *b* and have a shutoff cock *c* in the oil-supply pipe *d*. Insert a measuring rod *e*, graduated in inches from the bottom end, through the open manhole. Then run oil into the tank until the measuring rod shows a depth of one inch, and read the meter. The quantity of oil run in will be the quantity corresponding to a depth of one inch. Mark this down in the table, run in oil until the depth is two inches as indicated by the rod *e*, and read the meter again. If the meter is set at zero at the start, the second reading will be the quantity of oil at a depth of two inches, and so on for each additional inch.

If no meter is available and no similar method of measuring the quantity of oil run in for each inch of depth can be used conveniently, the table may be compiled by a series of calculations that are not difficult to make, though they are numerous and therefore apt to be tedious.

Assume, for example, that the tank in question is 28 ft. long and 8 ft. in diameter and that the ends are parts of spherical surfaces, with a rise of 10 in. at the center line of the shell. Make a scale drawing of the tank, as shown in Fig. 2, using as large a scale as possible, to obtain accuracy. On the center line *ab* find by trial a center *c* for a circle that will pass through the points *d*, *e* and *f*, and draw the circle *defg*, which will represent the sphere of which the bumped head is a part. The small circle *xyz* is a cross-section of the cylindrical shell.

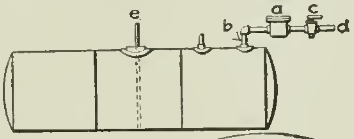

FIG. 1

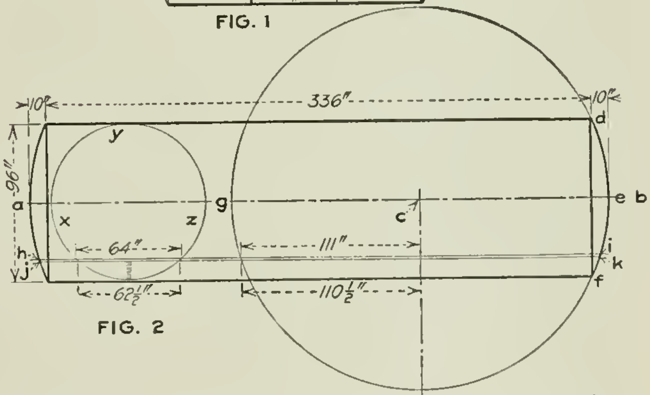

FIG. 2

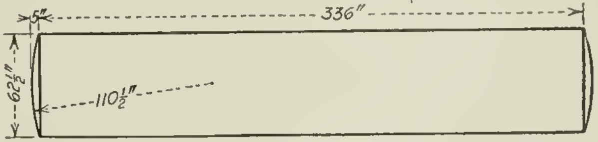

FIG. 3

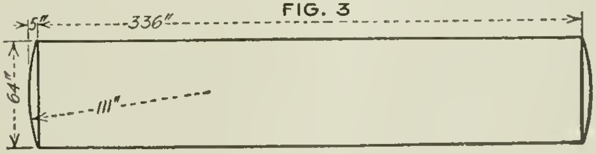

FIG. 4

METHODS OF OBTAINING MEASUREMENTS

Beginning at the bottom of the shell, draw lines parallel to the axis *ab* and one inch apart. These will divide the entire tank into 96 layers, each one inch thick, and the problem then resolves itself into finding the cubic contents of each layer. To illustrate the method to be followed, let the layer between the twelfth and thirteenth inches be taken.

First, draw two lines *hi* and *jk* at these two points. The lower surface of the layer will then have the shape and dimensions shown in Fig. 3 and the upper surface the shape and dimensions shown in Fig. 4. The sizes of both these sections are obtained directly from Fig. 2, as may be seen from the corresponding dimensions. As both sections are drawn to scale, the rise of the segmental end can be scaled. It will be found to be practically 5 in. in each case.

The area of the section in Fig. 3 consists of a rectangle 62½ x 336 in. and two segments whose diameter is 2 × 110½ in. and whose rise is 5 in. The area of a segment is found by the formula,

$$A = \tfrac{4}{3}H^2\sqrt{\frac{D}{H} - 0.608}$$

in which *A* is the area in square inches, *H* the height of the segment in inches and *D* the diameter of the circle of which the segment is a part. In this particular case

$$A = \tfrac{4}{3} \times 25\sqrt{\frac{221}{5} - 0.608} = 220\ sq.in.$$

and the area of both segments is 440 sq.in. The rectangular part has an area of 336 × 62½ = 21,000 sq.in. and so the total area of the section is 21,440 square inches.

By a similar procedure, the area of the segmental end in Fig. 4 is found to be 220 sq.in.—the difference between this and the end in Fig. 3 is so slight as to make no appreciable change in the area. The total area of the section in Fig. 4 is therefore 336 × 64 + 440 = 21,944 sq.in. Now, with sufficient accuracy for all practical purposes, the volume of the layer between *hi* and *jk*, Fig. 2, may be taken as the average of the areas of the upper and lower faces multiplied by the thickness of the layer, which is one inch; hence, the volume of the layer is ½(21,440 + 21,944) × 1 = 21,692 cu.in., or about 94 gallons.

The volume of each layer from the bottom to the center line should be calculated in this way. Since the layers between the center line and the top are of exactly the same size and shape as those between the bottom and the center line, but in the reverse order, the calculations will need to be made for only 48 different layers.

In calculating the volume of the first layer at the bottom—which is the same as the first one at the top—the area of one surface is zero; hence, the average area of the two faces of the layer is simply half of the area of the one surface whose area is calculated.

In making these calculations, extreme accuracy is a waste of time. If the areas are determined to the nearest ten square inches, the table will be quite accurate enough, for the diameter of the tank is not the same throughout because of overlapping plates and the graduated measuring rod cannot be read to small fractions of an inch. If the table values are worked out to the nearest five gallons, they will meet all ordinary demands.

It should be noted that the volume added by the bumped heads is 440 cu.in., while the total volume included by the layer is 21,692 cu.in. Thus the bumped heads contain 440 ÷ 21,692 = 0.02, or practically 2 per cent. of the total volume; in other words, if the heads were neglected altogether and considered to be flat, the error would be only 2 per cent. at the section shown in Fig. 2. At the level of the center line of the tank, where the head has its greatest projection, the error is still within 4 per cent. of the total volume.

Steel-Jacketed Electric Heater

The steel-jacketed electric heater unit indicated by the arrow in the figure has been put to innumerable uses in all kinds of industrial plants. Besides such applications as in crane cabs, valve, pump and meter houses, there have been scores of miscellaneous applications. The ease of conducting electric current to remote corners, to moving-crane cabs, etc., makes the use of electric heaters simpler than any other. The heater unit shown is of 500-watt capacity, can be connected in multiple to any alternating- or direct-current circuit where the voltage is not in excess of 250. Only as many as are actually required need be installed, and additions made when required as easily as adding electric lamps. Just as lamps are placed singly or in groups in locations where light is needed, so also are these units mounted singly or in groups in places where heat is required.

HEATER INSTALLED IN GAS-VALVE HOUSE

The units are flat like an ordinary meter, the dimensions being $\frac{3}{16}$ x 1½ x 23¾ in. All parts are inclosed, and no porcelain, cement, asbestos or molded insulation material used. The installation in the figure shows one of these units installed in a gas-valve house. These heaters are designed and manufactured by the Cutler-Hammer Manufacturing Co., Milwaukee, Wisconsin.

In offering "War-Savings Stamps" to the public the Government has made immediately available for every man, woman and child in the country a profitable, simple, and secure investment.

Editorials

Developing the Water Power

THE agitation for the development of the water powers has culminated in the submission to the President by the Secretaries of War, Interior and Agriculture, jointly, the draft of a proposed bill which embodies the fundamental principles of several bills now pending in Congress and seeks to avoid or cure their defects. The letter of transmittal, which will be found on page 135, outlines its principal features. A commission composed of the Secretary of War, the Secretary of the Interior and the Secretary of Agriculture, and having an executive officer who shall be appointed by the President, is to make investigations and to collect and record data concerning the power industry and its relation to other industries, and concerning the location, capacity, development, cost and relation to markets of power sites; to make public from time to time such portions of the information secured as it shall deem expedient in the public interest, and to issue licenses to citizens of the United States, or to any association of such citizens, or to any corporation, state or municipality, for the purpose of constructing, operating and maintaining dams, water conduits, reservoirs, power houses, transmission lines or other project work necessary or convenient for the development and improvement of navigation and for the development, transmission and utilization of power. The licenses are to be granted for definite periods not exceeding fifty years, and are irrevocable inside of that period, except for cause. Upon or after the expiration of the lease the United States shall have the right, upon not less than two years' notice, to take over any project covered in whole or in part by the license, upon paying a fair value, not to exceed the actual cost of the property taken, plus such reasonable severance damages, if any, as may be caused by the separation of said property from property valuable, serviceable and dependent not taken.

It would seem that under such a provision the Government would be powerless to exercise the right of eminent domain, no matter how badly the property might be needed, within the term of the lease, although there is provision that the Government may commandeer the plant temporarily in case the safety of the United States demands, for the purpose of manufacturing nitrates, explosives or munitions of war, or for any other purpose involving the safety of the United States, paying to the party, or parties, entitled thereto such just and fair compensation for the use of the property as may be fixed by the commission, on the basis of a reasonable profit in time of peace. It is not clear who shall exercise the right of recapture at the end of license period, on behalf of the United States, or who shall question or decide whether such recapture is advisable.

Inasmuch as the fifty-year license is insisted upon, in order that the licensee may get back his investment within the term of the license, it is not fair that the Government, at the time of recapture, should be expected to pay anything like the full cost of the project. A "fair value" is an indefinite and indeterminable quantity. It would be much preferable to retain the right to recapture at any time upon the restitution to the licensee of all that had been expended upon the property, less what had been retired in depreciation and discharged indebtedness.

The regulation of the issue of securities, the control of expenditures, and the fixing of rates, are left altogether to the public utilities commissions of such states as have such bodies, the newly created commission having the right to exercise these functions in states where no such bodies exist, but being obliged to surrender them to such bodies when created. We should have preferred to see such control unified and systematized in the Federal Commission, and to see, as one of the terms of the license, that the price of current should be fixed at cost plus a fair and stipulated profit. The commission may, in its discretion, give preference to applications for licenses by states and municipalities for developing power "for state and municipal purposes," but apparently not for the general use of its inhabitants.

An annual rental of not less than ten cents per horsepower is to be charged. Fifty per cent. of the charges arising from licenses for the occupancy and use of national forests is to be expended in the survey, construction and maintenance of roads and trails within such national forests. Fifty per cent. of the charges arising from licenses for the occupancy and use of public lands, national parks, national monuments and power sites reserved outside of national forests shall be paid into the Reclamation Fund. All proceeds from any Indian reservation shall be placed to the credit of the Indians on such reservations, and fifty per cent. of the charges arising from all other licenses is reserved as a special fund to be expended in the maintenance and operation of dams and other navigation structures owned by the United States, or in the construction, maintenance or operation of headwater improvements on navigable rivers of the United States. This rental will, of course, be an item in the rate-fixing charges and the users of the current will thus be taxed for the purposes named.

The licensee is required to furnish, free of cost to the United States, power for the operation of navigation facilities connected with the project, whether constructed by the licensee or by the United States. The licensee must commence the construction of the project work within the time fixed in the license, thereafter in good faith and with due diligence prosecute such construction and, within the time fixed in the license, complete and put into operation such part of the ultimate development as the commission shall deem necessary to supply the reasonable needs of the then available market. Should he fail to do so, the Attorney General, upon the request of the commission, shall institute proceedings in the District Court of the United States for the district in which any part of the project is situated, for the revocation of such license, the sale of the works constructed and such other equitable relief as the case may demand.

The time to fix definite terms is when one is making a bargain. The terms of the proposed license do not enable one to judge with sufficient accuracy how the price of the service rendered by the licensee is likely to compare with what it would cost if rendered by the Government itself.

The first step toward the passage of the foregoing bill was taken by the House of Representatives on January eleventh, by the adoption of a resolution providing for the appointment of a special committee of eighteen members to which shall be referred all bills and resolutions introduced during the Sixty-fifth Congress (except those touching foreign affairs), which deal with water-power matters. The committee, which will be named by the Speaker, will serve only during the present Congress.

The adoption of this resolution discharges the committee on Interstate and Foreign Commerce and the committee on Public Lands from further consideration of the various bills that have been before the House for some years, and these bills are to go to the new committee. The proposed legislation in regard to water power at Niagara Falls is left in the hands of the House Committee on Foreign Affairs.

A bill introduced in the House on January ninth is intended to give the President power to take posession and assume control of any water-power projects using the waters of Niagara River for manufacturing purposes. The bill further empowers the President to retain possession, management and control of these projects for such time as may appear necessary to him during the period of the war, and then to restore them to their original owners, who are to be paid a fair and just compensation for the use of their property, as determined by an impartial agency. The basis of this compensation is a reasonable profit in times of peace, to which must be added the cost of restoring the property to as good condition as existed at the time it was taken over, less the value of improvements made thereto by the United States during its tenure.

In connection with the question of Government control of water powers, it is significant to note that Governor Whitman, of New York, in his message to the Legislature, advocated the idea that the state should undertake to develop some of its unused water power, a large amount of which has been created by the construction of the new barge canal. After developing the projects, the state might either operate them itself or lease the plants to others.

The present activity in regard to water-power utilization indicates an acute appreciation of the urgent need of tapping sources of power as yet untouched, to relieve the pressure on the fuel industries and the transportation systems; and under the spur of necessity it is probable that the long delay will be succeeded by prompt, equitable and conclusive action.

Coal

COAL continues to be the principal concern of the power-plant owner and engineer. To the extra quantity required to meet the normal growth of the country has been added that required by the speeding up of industry and the increased activity of the railroads. Even if the mines could produce the additional quantity needed, the railroads cannot transport it, and the demand, the difficulty of transportation and the suffering due to the lack of fuel have been enhanced by unusually long periods of exceptionally cold weather.

Industries have been shut down, hotels and hospitals and homes without coal, street-car lines stopped, public utilities hampered, commutation service deranged, and all the habits and activities of the people overset because of the shortage of fuel.

All this has resulted in a wild scramble for coal, not only on the part of individuals, but of localities. Local officials and administrators have commandeered coal passing through their territories en route to other sections. New England and New York are contesting for priority. There is not coal enough for all. Some must get along without—but who?

Obviously, provision must first be made for the absolute essentials. Homes, hospitals, hotels and places where people are obliged to work must be kept warm, the people must be transported to and from their work, food must be prepared, distributed and cooked. There are many things for which coal is burned that might be spared temporarily, and there has been much talk of cutting off the fuel supply to nonessential industries, but this would throw thousands out of employment and be productive of widespread suffering.

The United States Fuel Administration made public on January eighth its "budget plan" of allotting the available coal supply.

Committees representing the large industries not engaged in war work—more than one hundred in all—will be called into conference with the officials of the Fuel Administration. They will be shown the amount of coal available for all purposes, the amount required for war purposes and domestic consumers and the total curtailment of the use of coal which must be effected to satisfy these demands.

They will be asked on patriotic grounds as well as for their own future interests to volunteer in behalf of their industry a reduction of the coal consumption for the year 1918. They will be asked to show the Fuel Administration the best method of accomplishing this curtailment. They will also be asked to advise the Fuel Administration as to how to arrange these restrictions so as to affect only the less essential portions of their own business if possible.

When an agreement is thus reached as to the quantity of coal to be conserved in each industry, the Fuel Administration order will be issued, making this agreement effective as regards the total industry involved.

The voluntary annual saving shown by the first dozen industries called into conference promises to be between fifteen and twenty million tons. The total offering, from all nonwar industries will be between thirty-six and fifty million tons for the year 1918.

Fuel needed in 1918 for Army and Navy purposes, for munition works, for public utilities, for domestic consumers, and for factories working on war material is scheduled in the budget for one hundred per cent. fulfillment. With this figure and the estimated production of coal during 1918 as a basis, a subtraction shows the amount of fuel left for nonwar industries.

All the large American industries which have so far met with the Fuel Administration have shown a willingness to go voluntarily just as far as necessary in curtailing their activity. The Fuel Administration asks that other industries affected get in touch with Washington without waiting for formal notice.

In the meantime the situation has become so acute that Fuel Administrator Garfield has ordered all manufacturing plants to shut down immediately for five days, and thereafter on every Monday up to and including March twenty-fifth. Certain exceptions are made in favor of plants that must be operated continuously seven days a week, those engaged in manufacturing perishable foods, and printers and publishers of papers and periodicals; also, fuel may be burned on Mondays to prevent damage to property from freezing. The situation will continue acute until a sufficient spell of moderate weather uncripples transportation, and the congestion which hampers the movement of freight can be relieved. All that the individual can do is to put up good-naturedly with disarranged service, and save, *save*, SAVE. Save fuel directly in every possible way—save it by burning fewer lights, by heating fewer rooms; save it indirectly and lessen the burden upon the transportation facilities by traveling as little as possible and buying nothing that you can get along without; for there is nothing that does not require coal and transportation in its production and delivery to you.

The Joliet Plant

ON OTHER pages of this issue is a description of the new Joliet plant of the Public Service Company of northern Illinois. Among stationary plants in this country it is one of the first to reach an operating steam temperature of six hundred and fifty degrees. At the Buffalo General Electric plant recently placed in operation the steam temperature is six hundred and eighty-nine degrees, obtained from a steam pressure of two hundred and seventy-five degrees. In the present case the superheat is less by fifty degrees but the pressure is greater, being three hundred pounds at the turbine and enough higher at the boiler, to insure the above density. It is probable that the boiler pressure will approximate three hundred and twenty-five pounds, the design still allowing an additional twenty-five pounds.

There appears to be some difference of opinion as to the choice of pressure or superheat in making up the total steam temperature. Theoretically, the advantage is on the side of higher pressures, but here mechanical difficulties place restrictions. To obtain a temperature range such as exists in the plant under discussion, a compromise is necessary. Pressure up to the present mechanical limits is employed and then superheat to increase the initial temperature and add to the efficiency. Other factors influencing the degree of superheat are steam density and condensation during expansion. Superheat reduces the density and lessens friction. It also tends to prevent liquefaction in the turbine and should increase with the pressure. It is evident, then, that pressure and superheat must go hand in hand, the ratio to be determined by existing conditions and the results obtained from practice.

While little trouble is expected in the turbine, as up to a certain point it is merely a case of using heavier construction at the first stage and perhaps additional stages to cover the wider range, it is different with boilers and fittings. At Joliet the limit in pressure has been reached for the standard design of large boiler. Experimental work is being conducted to develop boilers for the higher pressures, but some time must naturally elapse before any new design is ready for practical application.

While the arrangement of boiler and economizer at Joliet has been used for several years in some of the leading stations in Europe, it is new to this country, as is the use of the all-steel horizontal economizer. To withstand the high pressure, steel is more reliable than cast iron, but it is more subject to corrosion from low-temperature flue gases. Galvanizing the tubes should neutralize this action.

The design of the unit calls for height in the building, but not so much as for the individual detached vertical-tube economizer placed in the same location. The above-ground basement is another factor adding to the height, but this is counterbalanced to some extent by small overhead bunker capacity calling for no additional height and minimizing the steel requirements. One great advantage of this arrangement is the elimination of ash-handling equipment. Another feature is the economical use of floor space. With backs retreating to the rear of the bridge-wall, the boilers require less than three-tenths square foot per nominal horsepower based on ten square feet of heating surface. The figure given omits the overhang at the rear.

No comprehensive tests have been conducted at the plant, so that the increase in efficiency over average present practice is open only to estimate. Owing to the favorable conditions it is quite probable that the over-all boiler efficiency may exceed eighty per cent., a gain of, say, five per cent. over good average practice. Theoretically, the one hundred pounds pressure additional to that commonly employed in the larger plants makes possible a gain of between six and seven per cent. in the turbine, giving a steam consumption that will compare favorably with the best from the largest units. It would not be unreasonable to expect a net production of one kilowatt-hour on eighteen to nineteen thousand British thermal units.

Against this increase in economy must be charged the additional investment. It has been estimated that boilers for this high pressure cost about twenty per cent. more than those designed for pressures close to two hundred pounds. The piping, valves and fittings are also more expensive, but small diameters help limit the cost. An analysis of actual figures should show a net advantage to the plant well worth while.

An appeal has been made by the Machine Tool Section of the War Industries Board, Council of National Defense, to the machine-building industry to relinquish a large number of heavy machine tools which are urgently and immediately needed for making heavy guns. There is no time to have them built. They must be taken from shops that already have them in use. To their owners is given the opportunity of doing something for the service of mankind—something that will save thousands of lives and prevent hundreds from being crippled. In modern warfare big guns are a paramount necessity. Without heavy artillery to clear the way, the loss of life in assaulting columns runs up to forty and sixty per cent. With adequate artillery preparation the loss is reduced to three to five per cent. The sacrifice asked is small compared with that of the thousands of boys over there who are making the supreme sacrifice—all they've got.

Correspondence

High Speed of Steam Turbines

In the Oct. 2 issue of *Power* W. F. Shaphorst discusses the subject of high speed of steam turbines. I have also noticed C. H. Watson's comments on the same subject in the issue of Nov. 6.

Mr. Watson points out that an 80 per cent. overspeed test will be highly objectionable from the designer's point of view. In this he is, of course, entirely correct. For a given power not only would a more expensive and a less efficient machine result, but turbines of as high power rating as are now manufactured could hardly be produced with any materials available at the present time.

Neither of the writers, however, seems to have considered that an 80 per cent. overspeed test, in the majority of cases, would be far from conclusive evidence that the various parts would be able to withstand the stresses occasioned by such overspeed as the turbine may be put to as a result of the failure of its safety appliances to perform their functions. I believe it can safely be said that 75 per cent. of all the turbines manufactured in the United States today, if unleashed from the reins of their speed regulators and unloaded, would assume a speed in excess of 180 per cent. of the operating speed.

As is commonly known, the speed that a certain turbine will assume under these conditions depends upon several factors. The main factor is the relation between the steam and blade velocities. In the Rateau turbine this relation is, for the best efficiencies, commonly taken as 2.3, while the theoretical figure for small nozzle angles is 2. If the windage losses in the turbine were entirely neglected and the theoretical figure used, when the blade velocity had increased to such an extent as to equal the steam velocity there would no longer be a force component in the direction of rotation, and consequently the speed of the turbine would be twice the normal operating speed.

Using the practical figure of 2.3 and still neglecting the windage losses, the overspeed to which the turbine would be theoretically put would be 130 per cent. However, if the turbine has a low horsepower rating, the windage losses for this overspeed will amount to so much that the machine will be self-loading before it reaches this point. It is true that the steam would impinge on the back of the blades long before this point was reached, but the blade losses as a result of this would be only about twice as great as if the angle of entrance into the blade row were the same number of degrees smaller than the blade-inlet angle, as it is greater in the present instance.

Furthermore, a well-designed Rateau turbine has a bucket-entrance angle sufficiently wide to take care of a steam velocity corresponding, approximately, to 70 per cent. load, rather than full load, without shock on the back of the blades. For a Curtis turbine with two rows of moving blades, the ratio between steam velocity and blade velocity would be about 4.5, practically, and as a consequence, the theoretical speed at which a turbine of this kind would be self-loading would be 350 per cent. above normal. The Parsons turbine would theoretically become self-loading at 100 per cent. overspeed. Here, as well as for the straight Rateau turbine, it is true that windage and blade losses would make the turbines of ideal condition self-loading long before reaching the theoretical point.

While the foregoing figures are those for the ideal conditions, a very small percentage of turbines are manufactured, in which such relations between steam and blade velocities actually exist. The figures are almost always greater. The reason for this, as is easily understood, is the fact that the frames required to make turbines commercial for small capacities will ordinarily be smaller than the frames at which they would give their best steam rate.

While high speed for steam turbines of larger type is a relatively new practice, as Mr. Shaphorst points out, in the field of small turbines, on the contrary, the last decade has shown a falling off in popularity of extremely high speeds. Instead of using single-stage units of 30,000 to 40,000 r.p.m., we are now generally employing 5000- to 7000-r.p.m. geared machines, and from 1000- to 4000-r.p.m. direct-connected.

There is no reason why a well-designed and intelligently operated high-speed turbine should not be as safe as a lower-speed machine. In some instances the drive is of such a nature as to render unnecessary any governor or overspeed device. For instance, in case of a blower or fan the additional resistance experienced for overspeeds is so great as to keep the unit from increasing its speed unless the runner on the fan should break for some reason or other. It would, therefore, generally be safe to leave off all governor mechanisms for a blower unit.

With the centrifugal pump it is generally considered allowable to leave off the governor and run the turbine with an emergency governor alone. This is also true of turbines used for ship propulsion.

For a generator unit, as Mr. Watson points out, there are always supplied the main governor and an emergency trip governor, these two safety devices being entirely independent of each other. The main governor is sometimes operating the steam-admission valve directly through a lever or a linkage, and in some instances the valve is handled by oil or steam pressure, regulated by a pilot actuated by the governor. The design of linkage and pilot-valve arrangement offers opportunities to guard against accidents. For instance, if any part of a properly designed governor mechanism should break, the valve should always close. If the pilot spindle should unscrew or be broken off, its motion should always be such as to admit oil or steam on the side of the operating piston, which would make the valve close. Furthermore, a spring or a small steam cylinder should be arranged over the valve so that in case the oil pressure failed the turbine would shut down. On low-pressure turbines, operated at, say, 2 lb. back pressure and 28 in. vacuum, it is generally considered good practice to install a vacuum breaker actuated by an emergency governor, in addition to the trip valve in the inlet of the turbine. In fact, the trip valve is often left off entirely and the vacuum breaker depended on to keep the turbine from running away, and this is generally safe.

In high-speed turbines there are certain characteristics that may give rise to trouble if design is not properly made. The one most commonly talked of is the flexibility of the shaft. As Mr. Watson says, impulse-type turbines are generally made to run somewhat above their first critical speed. This is also, I believe, a good practice. A turbine rotor will generally run with less vibration after it has gone through its first critical speed than before this point has been passed. This is a fact commonly known and recognized by all turbine builders, and contrary to Mr. Watson's supposition, the larger of the reaction turbines for land work also have flexible spindles and run through their first critical speed before coming up to operating speed. For marine turbines this condition is, of course, not allowable, since a marine turbine will be called upon to operate at any speed below its maximum running speed.

A turbine of any kind can generally be made to operate the best between the first and second critical speeds, but if the shaft is so flexible that the turbine is allowed to pass through the second critical speed before reaching the operating speed, if these critical speeds do not come more than 3000 r.p.m. apart, and unless the turbine is in perfect balance, it is often difficult to obtain smooth running at operating speed.

The bearings for high-speed turbines have occasioned a certain amount of difficulty in the past, when the theory regarding the proper way of admitting the lubricant to the bearing was still obscure. The more recent practice for high-speed bearings is to use only a part of the available bearing surface at the top and bottom of the bearing and use the remaining space to build up the oil film under the journal. Bearings made in this manner generally permit of the use of far higher surface speeds and pressure intensities than those of the older type.

Wellsville, N. Y.

Piston Packing Burns Out

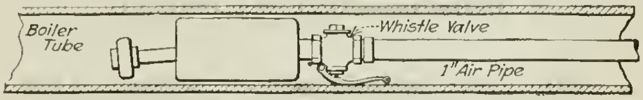
I am up against a puzzling problem. We have two Ideal engines 9 x 10 in., making 205 r.p.m. with 100 lb steam pressure and direct-connected to generators. They sometimes run for several weeks without giving trouble, then, presto! the piston rod gets so hot that the packing in the box is burned out. We use a good grade of cylinder oil fed by automatic force-feed pumps. The packing is of a good grade, costing $1.50 per pound, and is kept in A-1 condition. Sometimes the heating occurs shortly after repacking and at other times not for some weeks.

I have asked different engineers, including the experts from the engine shop, and no one seems able to explain the cause. Recently, we spent $1000 having the engines overhauled and put into good condition by the makers, but still the rod will occasionally heat and burn the packing. The piston and rod are properly centered, and the load is never excessive. I have never heard of a similar case, but some readers may have been troubled in this way and solved the problem.

Portsmouth, Ont., Canada. JAMES E. NOBLE.

Air Control for Tube Cleaner

In removing scale from a fire-tube boiler, we use a compressed-air tube cleaner that is attached to a 14-ft. length of 1-in. pipe. In operating this cleaner it required one man to open and close the air valve every time the cleaner was changed from one tube to another. I found an old whistle valve and screwed it to one end of the tube cleaner, attached the pipe to the valve and left the valve on the air line open. When the cleaner enters the boiler tube, the lever on the whistle bears against the tube and opens the valve, thus admitting air to the cleaner. When the cleaner is withdrawn from the tube, the spring closes the valve. This arrangement is shown in the accompanying sketch and is repeated each time the cleaner is pushed into the tube.



WHISTLE VALVE ATTACHED TO TUBE CLEANER

JOSEPH MCCUMBER.
Grinnell, Iowa.

Fuel-Saving Suggestions

In *Power* of Dec. 11, Mr. Bromley gives directions for saving coal in power plants. The article is very good, and with a comment on the method advocated of cleaning fires I would give it approval. "Jumping" ash and clinkers over clean fuel is impractical and results after hard work in only half-clean fires. It is not done so "in our set this season." I also believe Mr. Bromley overlooked the great advantages of shaking grates in furnaces. Now, above all times, it is opportune to recommend the shaking grate, as it is without doubt a valuable asset to fuel saving.

The shaking grate is not new. It was introduced many years ago, and the principle was recognized at once as sound and logical. The very desirability of some such device induced many makers to go into the business of turning shaking grates out as fast as possible.

The result was that many of the grates were not strong enough for the hard usage encountered in many of the installations, and the shaking grate got a "black eye" from which it has not yet recovered, notwithstanding the great improvements made.

In every instance where a stationary grate is used, a large saving of fuel would be made if a shaking grate were substituted, and I believe Mr. Bromley will agree that every effort should be made to induce engineers to use all their influence to have this style installed, instead of the original and old-fashioned stationary grate.

Somerville, Mass. JOHN M. COLEMAN.

["Jumping" the fire was considered because of the very extensive use of the stationary grate. The shaking grate is desirable.—Editor.]

Static Electricity from Gasoline

The following experiment will show that gasoline will create enough electricity in flowing from a spigot to ignite itself. Insulate a can from the ground and draw gasoline into it from a spigot near to but not touching the can, and the composition of the gasoline is such that it will create static electricity in the can and discharge in sparks when it gets up to the neck of the can, so that it can jump across and an explosion will occur. This has happened in several instances, and even if the spigot is grounded, electricity will still be generated in the can. The only way to prevent the explosion is to ground the can to carry it off.

This is a new one on me, and it seems to be the composition of the gasoline that causes it, as other liquids have been tried with no such results. D. R. HIBBS.

New York City.

Controlling Smoking Chimneys

The smoke-preventing system described on page 718 of the Nov. 27 issue of *Power* is very good for a large power plant, but it would be rather expensive for a small one. Following are a couple of methods that may be employed to watch the smoke and assist in keeping it down to the proper density and that can be used by almost any plant, no matter how small. Some of the small plants have more trouble with smoke than the large ones, as they do not have as efficient methods of operation; and there is more complaint in a small place, as many of the homes are owned by the tenants.

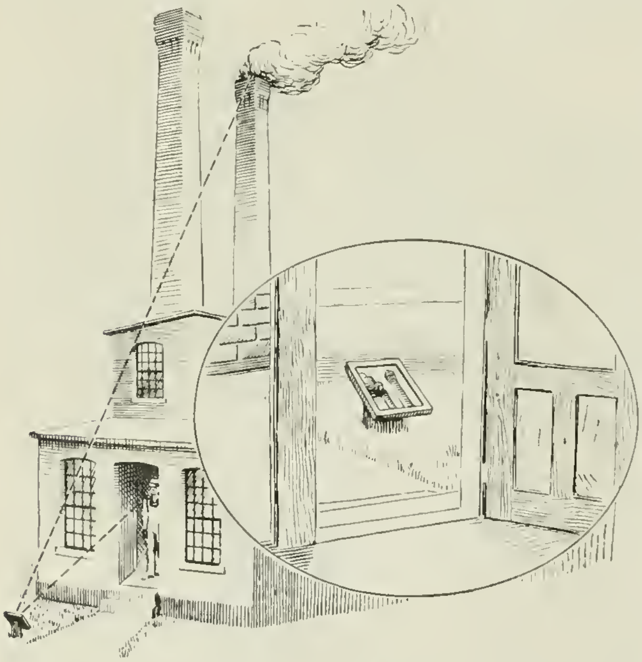


FIG. 1. SMOKE OBSERVATION MIRROR IN THE YARD

One method of smoke observation is to place a post in the boiler-house yard with a mirror attached to it and set at such an angle as will enable the boiler attendant when standing in the doorway (see Fig. 1) to easily observe whether his chimney is smoking or not. If it is, he can remedy the cause.

The other method can be used only in boiler plants in which the chimney rests on the top of the boiler. A 2-in. pipe is put through the stack at such an angle that the fireman can see through it from the floor. The pipe has several large holes drilled through it to admit the smoke, but not large enough to affect the draft. An electric light is hung at the top end of the pipe, as shown in Fig. 2. When the fireman looks through the pipe, he can see at a glance whether the light is clearly visible or not. The clearness with which the light can be seen, of course, indicates the smoke condition. D. R. HIBBS.

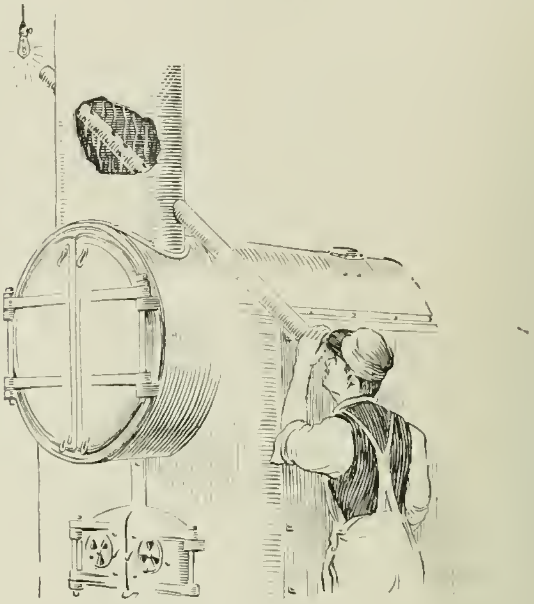

FIG. 2. SMOKE OBSERVATION PIPE IN STACK

New York City.

Unsatisfactory Plant Conditions

When I took charge of this plant, which comprises three generating units of medium size, I found that the governors on two of them were so badly corroded and sticky that with the least fluctuation of steam pressure or load they would race badly or slow down. The governors were immediately cleaned and put in order, and no further trouble has ever developed. The smallest of the three engines would remind one more of a trip-hammer than a steam engine. The former chief informed me that the knock was born in the small unit and that no means could be found to remove it, but I can truthfully say now that I never saw a more quiet running engine, and a coin will stand on edge on different parts of the engine and bedplate.

A great deal has been said on the coal question, and most writers hold to the point that the engineers are the ones charged with the saving of coal. To a certain extent this may be true, but assuming that one has done all in one's power to cut down on coal, such as cleaning boilers, stopping leaks in boiler walls and cleaning stacks, and is getting the best results possible under existing conditions, but is still burning more coal than should be consumed, with black smoke belching from the chimney continuously, and after satisfying oneself that an investment of a few hundred dollars would cut that coal bill, the owner should refuse to make the investment, what should one do? I think I know the answer most engineers would make. M. E. WEBBER.

Syracuse, N. Y.

Sandpapering Brushes

In sandpapering the brushes of modern motors, I have found that, where the brushes fit well in the holders, it does not make much difference whether the sandpaper is drawn in one direction only or back and forth. In up-to-date machines the brushes usually make a good fit in the brush-holders. In the older machines the brushes often fitted loosely in the holders, and then difficulty was likely to be encountered unless the sandpaper was pulled only in the direction of rotation of the machine. However, it is safe always to pull the sandpaper in one direction; that is, in the direction of the rotation of the machine. T. A. NASH.

New York City.

Warning of Impending Danger

Some readers of *Power* no doubt have had experience with flywheel explosions and are "alive to tell of them." There surely must have been some warning or a series of warning incidents, if properly interpreted, preceding the explosion. From experience we recognize the sound when valves "grind" for want of better lubrication or when water is heard in the cylinders. If all strange sounds are immediately investigated, there is a remedy for such things if applied in time. While alone on watch, I have often wondered what incident would occur? What sound would be heard which would be a sign of impending disaster—that the flywheel was on the point of rupture? How many readers could describe the series of events leading up to a flywheel explosion? Would not such a discussion be of great value?

A young man walked into our station one night, introduced himself as an engineer and asked to look around. I showed him around, answering his questions and in turn asking some. We stopped in front of the 300-kw. unit which was running at the time, and he asked if I had had any experience with flywheel explosions. My answer was in the negative, but in reply to the same question to him, he said that he had and told the following:

Several years previously he was working in a certain manufacturing plant as a sort of wiper and making himself generally useful about the place. There were two units, duplicates. The flywheel of each weighed approximately 14 tons and operated at 100 r.p.m. One day toward noon he walked into the engine room to help fill cups, etc., during the shutdown. Suddenly a "whistling" sound came from the flywheel—something that had never been heard before. An old timer at engineering urged an immediate shutdown of the engine as a flywheel explosion was impending. The whistling increased while the throttle was being closed, and the men "scattered for the open air." The whistling continued as the engine gradually slowed down, then the flywheel suddenly went to pieces; but the damage was comparatively slight, for which everyone felt grateful to the old timer.

According to the young man's narrative, then, if an engineer heard a whistling or other unusual noise coming from a revolving flywheel, he would be justified in shutting down and investigating. Anyway, by so doing he would be playing on the safe side. I hope there will be a discussion that will give a clue in regard to such explosions, and surely there are many engineers who will appreciate it. THOMAS M. GRAY.

Middletown, N. Y.

United States Navy Service Flag

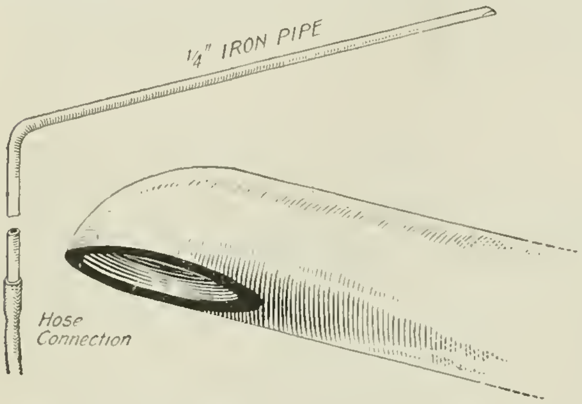
With the usual service flag there is no way of distinguishing the particular branch of service represented. Being in the Naval service, I took occasion to make a service flag for my own home and decided that anybody who should see it would recognize the branch of service represented. I took a white line and made some of the most attractive navy knots and placed the cord in a continuous line around the white panel. At the top and bottom there is a double Carrick bend and on each side, at equal intervals, a figure-of-eight and a square knot. Since sending the flag home, I have heard that it is considered not only attractive, but leaves no doubt as to which branch of the service I am in.

SERVICE FLAG TO DESIGNATE THE SERVICE

New York City. M. M. CLEMENT.

Cleaning Turbo-Alternators

The importance of keeping the windings and air passages of turbo-alternators free from dirt is well known and cannot be overstated, and it is not a difficult job with some types of generators at least. We use compressed air through a ¼-in. iron pipe, bent as shown in the illustration, for blowing out 5000-kw. generators.



BLOWPIPE FOR CLEANING GENERATORS AND MOTORS

The lance is long enough to reach halfway through the generator, and from the long-radius bend to the hose connection is about two feet; this serves as a handle, and it also indicates the direction of the blast when the lance is in the generator. With the end shields off the generator the lance may be inserted between the field and armature, and the powerful blast of air, issuing at right angles to the pipe, blows through the windings and laminations, effectually removing the accumulated dirt. It takes four men from eight to ten hours to do the whole job and get the machine ready for service again. H. W. MORREALL.

Utica, N. Y.

Preventing Lamps Burning Out

Recently, I had several flood lights to install on a 220-volt circuit, therefore the lamps were wired two in series. After the lights were put in service, considerable trouble was experienced with the lamps burning out, owing to voltage surges in the line serving the property.

I have been able to reduce our lamp loss from this cause by connecting, in series in the line, about a thousand feet of No. 8 wire, leaving the wire in the form of a coil, which seems to act as a choke coil. Since doing this I have lost only two lamps in two weeks. Previous to the installation of the coil the loss was two or more every night. C. W. YOUNG.

Tulsa, Okla.

[The experience related is no doubt a case of operating the lamp on too high a voltage. This could have been remedied by finding out the correct voltage and installing the proper lamps.—Editor.]

Regulation of Feed Pumps

A large number of plants using steam heating or drying coils, and draining the condensate and drips back to an open heater to save the heat as well as the water itself, lose a large part of the returns through the heater overflow because of the limited storage space and improper operation of the feed pump.

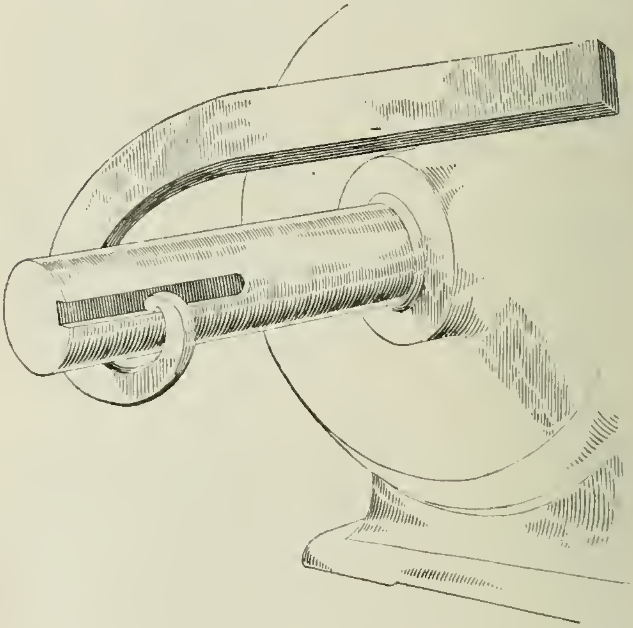
Frequently, the pump is speeded up and the boilers filled with water during times when the volume of returns is not sufficient to make up the feed supply and cold water is automatically supplied. The pump is then shut down, and the returns fill the storage space of the heater and overflow, carrying away valuable heat. The pump should be so adjusted as to deliver the return water continuously to the boiler at the rate at which it is coming back, and as a result none will be wasted at the overflow.

Such regulation of the feed pump in one plant cut down the use of makeup water by one-third and gave an even feed temperature of 210 deg. F.

Philadelphia, Penn. M. A. SALLER.

Spanner Wrench for Finished Shafts

The illustration shows a spanner wrench for shafts, which has proved so useful that I want others to know of it. It is made of 1 x ½-in. steel, and the same wrench can be used on shafts from one to six inches in diameter without damaging the keyway. The shape of the tool is the result of something like two years' evolution. It is christened the "Twister" and is used for rotating (by hand) armatures and the like during the process of erection, repairing and inspection, and of course it works equally well on other similar things. The need of something of the kind is shown by the condition of keyways on shafts so frequently found damaged by the use of monkey wrenches and pipe wrenches.



WRENCH TO ROTATE A SHAFT

Brooklyn, N. Y. A. J. CAHEN.

A point about the arrangement of blowoff piping, which is often overlooked and may lead to a serious accident, is failure to see that the pipe system drains thoroughly by gravity to the discharge point. A pipe that remains partly filled with water, that becomes cold between the times, is likely to cause severe water-hammer that may break the fittings and may scald the operator.

Inquiries of General Interest

Collapsing vs. Bursting Pressure of Tubes—Will a flue or tube of a boiler resist a greater internal or external pressure? L. L. S.

On account of the impossibility of constructing flues or tubes of true circular form, or of their maintaining circular form when subjected to external pressure, they fail by collapsing from less pressure applied externally than the internally applied pressure required for bursting them.

Theoretically Maximum Percentage of CO_2—What is the theoretically maximum percentage of CO_2 in boiler-flue gases resulting from complete combustion of a pound of carbon? J. H. K.

With complete combustion, and only enough air present to burn the carbon, the flue gas would show only CO_2 and N, as all of the oxygen would be combined with the carbon. As air consists by volume of oxygen 0.207 part and nitrogen 0.793 part, the flue gas would show 20.7 per cent. of CO_2 and 79.3 per cent. of nitrogen, because CO_2 occupies the same volume as the oxygen from which it is formed.

Advantages of Subdivided Steam-Heating Surfaces—For warming a room by steam heat, what advantages are to be obtained by employing two direct radiators in place of one? C. C. P.

For the same amount of heat given out there will be the same amount of steam required, but when appropriately located, two or more radiators may be so placed as to give more uniform distribution of the heat throughout the space that is to be warmed and thereby effect a saving by not requiring overheating of a portion of the space to obtain sufficient warmth throughout the whole space. Another advantage is that with the heating surface divided the amount of surface used can be better adapted to requirements of weather.

Troublesome Radiator—In a low-pressure two-pipe gravity-return steam-heating apparatus fitted with direct radiators, one of the radiators fills up with water and will not circulate properly. What would remedy the trouble? A. W. F.

The radiator may not have large enough steam supply to maintain sufficient pressure for discharging the water against the pressure in the return main. This trouble is likely to occur when drips or other radiators at a higher level or more active radiators on the same level are connected into the same dry return line. If the troublesome radiator has ample steam supply, it should be made to return as well as others on the same level by giving it a separate return connected to the return main well below the water line of the boiler.

Variation of Power Required for Vacuum Pump—Is more power required for driving a vacuum pump with a high or a low vacuum? T. C. E.

The energy required depends on the net pressure or difference of pressure on each side of the piston. Hence with a single-acting air pump or any type of vacuum pump working at constant speed against atmospheric pressure, the higher the vacuum the greater the power required for its operation. But with a double-acting vacuum pump, operated at constant speed, the higher the vacuum the less the power required, as the average pressure on the discharging side becomes less the higher the vacuum in the condenser. With a perfect vacuum the difference of pressure would be 0 and the power required for operation of the pump would be only that required for overcoming friction.

"Lead" or Clearance of Large Bearings—What is a practical method of determining the setting that should be given to the boxes of a large crankshaft? F. M. F.

For stationary engines the amount of "lead," or radial clearance, is commonly adjusted by setting the capscrews or nuts down hard and then backing them off such a fraction of one turn as to permit a clearance between the journal and bearing that has been determined to be suitable for the special conditions. For large bearings having good working surfaces, radial clearance of 0.008 to about 0.014 in. usually will be found satisfactory. The actual amount of clearance obtained by "setting down hard and backing off" may be approximately estimated by multiplying the pitch of the screw threads by the fraction of a complete turn backed off; thus with screws having 7 threads per inch, backed off "one-half of one flat" of a hexagonal nut or bolt head, or $^1/_{12}$ of a complete turn, the approximate clearance would be $^1/_7 \times {}^1/_{12} = {}^1/_{84}$, or about 0.012 in.

Check Marks on Drawings—What are the advantages and disadvantages of leaving check marks on mechanical drawings? J. A. P.

The purposes of mechanical drawings are better served by omission of any lines or markings that do not add to exactness of interpretation. There can be no objection, however, in leaving check marks on private copies of drawings in hands of the makers as information for what it may be worth, to indicate that the dimensions or other features check-marked have been criticized or have received special consideration. But the presence of such marks detracts from general clearness of representation and from concentration of the reader, and it is better to omit them from drawings intended only to impart information of design or construction, unless the marks are used sparingly and for attracting special attention.

Computing Power of Compound Engine—What is the formula for computing the indicated horsepower of a compound engine? R. D. B.

The power developed in each cylinder may be estimated separately as a simple engine by the usual formula

$$I.hp. = \frac{P\,L\,A\,N}{33{,}000}$$

in which

P = Mean effective pressure, lb. per square inch;
L = Length of stroke, in feet;
A = Area of piston in square inches;
N = Number of single strokes per minute.

Then, adding together the number of indicated horsepower for each cylinder gives the total power developed.

When, as is generally the case, there is the same length and number of strokes in each cylinder, a more convenient method of computing the gross power of the engine is to assume that the m.e.p. of both cylinders are combined and referred to one of the cylinders (as the low-pressure cylinder) and assume that the whole power is developed in the cylinder thus referred to. If d = diameter of the high-pressure cylinder, D = diameter of the low-pressure cylinder, M = m.e.p. of the high-pressure cylinder, m = m.e.p. of the low-pressure cylinder, then the m.e.p. of the high-pressure cylinder referred to the low-pressure cylinder would be $M \times d^2 \div D^2$; the combined m.e.p. referred to the low-pressure cylinder would be $\frac{Md^2}{D^2} + m$, and the gross power of the engine would be given by the formula

$$I.hp. = \frac{\left(\frac{Md^2}{D^2} + m\right) \times L \times 0.7854D^2 \times N}{33{,}000}$$

[Correspondents sending us inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

Effects of War Conditions on Cost of Electric Service

Owing to the number of requests for regular institute meetings by the different sections of the American Institute of Electrical Engineers, it was decided to hold intersectional meetings, in which nearly simultaneous sessions are held in two or more cities, to consider the same papers. In accordance with this plan the 336th meeting of the institute was held in Boston, Jan. 8; in New York City, at the Engineering Societies Building, Jan. 11, and in Chicago, Jan. 14. The same paper was presented and discussed at all three places.

The success of these meetings, especially at this time, when the engineers of the country are overtaxed with the duties involved as an outcome of the war, thoroughly justifies these intersectional meetings. A record number was in attendance at all three meetings. One paper, "Effects of War Conditions on Cost and Quality of Electric Service," by Lynn S. Goodman and William B. Jackson, was presented at all three meetings. Mr. Jackson presented the paper at Boston and New York. I. M. Cushing, secretary of the Boston section, presided at the Boston meeting, and President E. W. Rice at New York City.

Mr. Jackson, as an introductory to the presentation of the paper in New York, gave a brief outline of the war situation for the past year, pointing out that when viewed in a narrow way the outlook was not very promising, but viewed with a broad range of vision the outlook for the United States and her allies could be nothing else but optimistic, and that the outcome would be of material benefit to this country. Likewise in the power industry, when viewed in a small way, the outlook creates pessimism, but when considered from the larger angle there is every reason to believe that the situation will be successfully met.

The paper deals more particularly with the effect of war conditions upon electric-light and power service, but the principles relate in their broad application to every kind of public-utility service.

DIRECTIONS IN WHICH THE EFFECTS APPEAR

The principal directions in which the effects of war conditions on electric service appear are:

1. In relation to operating: (a) In increased salaries and wages paid for operating; (b) in difficulty of retaining trained operatives and, conversely, the need to operate with partly trained forces; (c) in increased cost and difficulty of obtaining fuel and in reduction of its uniformity and quality; (d) in increased cost of other supplies and materials for operation and maintenance; (e) in the need for protecting the properties against enemy agents; (f) in increased taxes; (g) in possible decrease of consumption of electric power by ordinary customers; (h) in possible changes of load factor.

2. In relation to extensions of plant: (a) In the necessity in many cases for quickly caring for large accessions of permanent and temporary business; (b) in increased cost over normal for plant required to care for additional business; (c) in high cost for money and difficulty of obtaining it at any rate considered reasonable in normal times; (d) in the difficulty of obtaining equipment in reasonable times of delivery.

The effects of the war conditions are being manifested not only in the matter of heavy increases in operating costs, but also in the matter of extraordinary increases in cost for new plant required to care for added business. These conditions have already increased the operating expenses of the electric companies of this country to the extent of over $116,000,000 per year, as hereafter shown. This points to the necessity of readjustment to the new conditions without delay, while at the same time requiring readjustment to abnormal labor conditions.

An analysis of the United States Census statistics shows that the increase in the average wages paid per employee (exclusive of general officers, managers and superintendents) during the ten years from 1902 to 1912 was 11 per cent. During the war period thus far, salaries of officers, managers and general superintendents have in general not greatly increased, but increases in wages in the operating departments have ranged from 15 to 50 per cent., and it is the opinion that 25 per cent. may be taken as the average increase thus far occasioned by the war.

Under normal growth from 1912, at the rate indicated by the growth during the previous ten years, we find that the salary and wage disbursements of electric companies in the year 1917, had there been no unusual disturbance, should have amounted to $90,000,000, of which one-seventh would have been for general officers', managers' and superintendents' salaries and six-sevenths for wages. From this it is seen that the increase in wages of 25 per cent. means an outlay on the part of the electric companies of $19,000,000 for the year.

INCREASED FUEL COST TO ELECTRIC COMPANIES

Estimates based upon the United States Census reports show that the fuel cost for all the electric companies in the United States would have reached $50,000,000 for the year 1917, under normal conditions of the country, and would have amounted to about 60 to 65 per cent. of the normal generating expense. Definite information as to the amount of increase in fuel cost for the whole country is not available, but from information obtained from various sections of the country the conclusion is arrived at that the average cost per ton of coal to electric companies has increased a little more than 100 per cent. on account of war conditions, and that 100 per cent. is not far from correct. On this basis the increase in total cost due to the enhanced price per ton of fuel is $50,000,000. A conservative figure for the increase in tonnage due to lower quality and non-uniformity of grade is 10 per cent., which means an added increase of $10,000,000, making the total increase $60,000,000.

An estimate of the output from steam-driven electric central stations which might have been expected for 1917 under normal conditions shows 13,000,000,000 kw.-hr., and an average requirement of three pounds of coal per kilowatt-hour of output shows that the fuel requirements would amount to not over 20,000,000 net tons, which is approximately 3 per cent. of the estimated output from the mines for 1917. It is thus seen that a relatively large reserve supply of coal in the hands of every electric company would tie up but a very small part of the coal supply of the country and this supply would be widely distributed and to a certain extent would be in proportion to the populations and industrial importance of the several sections of the country.

The indications are that the cost of materials and supplies other than fuel, which is estimated as a little over 15 per cent. of the total operating expense, has increased as much as 75 per cent. Such an advance in this expense means an increase in expenditures in the neighborhood of $30,000,000.

INCREASED TAXES PAID BY ELECTRIC COMPANIES

Estimates based on the United States Census returns indicate that the 1917 taxes paid by electric companies might normally have reached $25,000,000. The proportion of gross revenue required for taxes has apparently been increasing year by year, having been slightly over 3 per cent. in 1902, a little over 3.5 per cent. in 1907, and nearly 4.5 per cent. in 1912. An estimate of the amount of the expense which may be expected to be added to the cost of electric service throughout the country from increased taxes is difficult of determination, but we may hazard a guess that the increase over normal expense will lie between $5,000,000 and $10,000,000 for the year 1917.

Summing up the foregoing amounts shows that the extra expenses now imposed on the electric companies on account of war conditions amounts to the immense aggregate per year, as follows:

Increased salaries and wages chargeable to operating	$19,000,000
Increased cost of fuel	60,000,000
Increased cost of other materials and supplies	30,000,000
Increased taxes	7,500,000
	$116,500,000

This amounts to a quarter of the normal estimated gross revenue for 1917 of all the electric companies, and it wipes out two-thirds of the sum that would have been available for interest, dividends and surplus. It does not include additional expenses caused by the difficulty of retaining trained operatives and the cost of protecting the properties against malicious interference, the magnitude of which we are unable to estimate. It puts the electric companies in a critical position, which is rendered more ominous by the impossibility of foretelling how much larger these extra expenses may become in future months.

Effect of War Prices on Power Industry

The effect of war prices on the electric-light and power business may be shown in the aggregate. The United States Census of central stations shows that the total revenue received from operation and other sources by all central electric-light and power systems (including both hydraulic and steam stations) in 1912 was in round figures $302,000,000 and the total operating expenses, including taxes and renewals and replacement expense, but not including interest on debt, was $184,500,000, leaving a total income of $117,500,000. The reported cost of construction and equipment was $2,176,000,000. Extension of these totals to the year 1917 shows that under normal growth the total revenues in 1917 would have reached $475,000,000 and the operating expenses, including taxes and renewals and replacement expense, would have reached $290,000,000, making the total income before deducting interest on debt, $185,000,000. Estimating the reported cost for construction and equipment would have grown to $3,500,000,000, an increase of 60 per cent. in five years, the income mentioned would represent 5.3 per cent. of this cost of construction and equipment. If no other factors entered into the problem besides increases in cost of operation, and assuming these increases effective over the whole year, the fuel expense, as before pointed out, would increase $60,000,000 for 1917, other supplies $30,000,000, labor expense $19,000,000 and taxes $7,500,000, representing an aggregate increase of operating expenses for these items of $116,500,000. This is an increase of 40 per cent. in operating expenses, and it reduces the divisible income to $68,500,000, which amount is equivalent to less than 2 per cent. on the cost of construction and equipment. This percentage is still lower in the case of the steam-electric systems of the country taken alone, and additional expenses for training new employees and the lowered efficiency of such employees, the cost of special policing, etc., reduce the amount still further.

What has been pointed out in the foregoing regarding the effect of war conditions on central-station electric service is also applicable to the cost of power produced by private power plants. The immensity of this field is seen by reference to the United States Census of Manufacturers for 1914, in which the total primary power reported as used in this field aggregated 22,500,000 hp. (exclusive of isolated electric plants for office buildings, hotels, etc.), of which 15,700,000 hp. was comprised of steam-driven equipment and only 3,900,000 hp. was in the form of purchased electric power. The central-station steam and water-driven electric generating capacity in 1912 was only 7,500,000 hp., with a probable 9,000,000 hp. in 1914.

Power Output of Industrial Plants

Considering the output of power by the industrial plants using steam power, which do not now purchase electric current, estimated on the basis of the capacity of equipment as reported for 1914, operating at the equivalent of full load for a sixth of the time, the total horsepower output would amount to 23,000,000,000 hp.-hr. It is safe to say that at least three-quarters of this is such that the exhaust steam cannot be effectively used for heating purposes and there would be a possible saving of at least 1.5 lb. of coal per horsepower-hour through service of this three-quarters from central steam-driven electric stations, making a total saving in fuel of 13,000,000 tons of coal per year under the industrial plant output for the year 1914. The saving would be much greater when considering only the more modern and economical central stations. The same considerations apply to the field of isolated building and hotel electric plants where conservation of coal amounting to millions of tons could unquestionably be effected.

The result of the increased cost of producing electric power in England, and also the curtailment of certain classes of service not yet experienced in this country, has been quite a universal increase in rates, in some cases flat percentage increases of the same amount for light and power, in other cases differing percentage increases for light and power, and in still others increases depending upon changes in cost of fuel. These flat percentage increases have varied from less than 10 per cent. to as high as 50 per cent. over the rates in effect prior to the war, London rates having been increased 50 per cent., according to the London *Electrical Review*.

The authors in the paper also point out that the economical central power-generating station is the proper medium for the supply of the large-power requirements arising on account of the war, and the many advantages of this means of producing and distributing power. These advantages, they say, are so large that it is advisable for the Government to use every reasonable means to encourage the central-station companies and discourage individual power plants during the period of the war. Certain operating economies and changes which might be adopted by the central-station companies, if forced to it by war conditions, are also considered.

The paper brought forth a vast amount of discussion. Among the opinions expressed was that when the exhaust steam could be used for heating and manufacturing purposes, power could be produced just as cheaply, in the isolated plant, if not at less cost, as in the central station.

H. M. Hobart, who had recently returned from England, called attention to the 50 per cent. increase in the rates for electric service in London being an exceptional case, as it was doubtful if there had been any increase in the rates in many localities in that country. He also pointed out that the increased cost of each item entering into the production of power should not be considered as directly affecting the cost of power, since the output of the central station has also greatly increased.

The pooling of power of both central and private plants, and if necessary the commandeering of private plants, was suggested as a means to help supply power to the essential industries for carrying on the war.

In Re Proposed Water-Power Legislation

"Joint letter" from the Secretary of War, Secretary of the Interior and Secretary of Agriculture, addressed to the President, regarding the proposed water-power bill.

My Dear Mr. President: We transmit herewith for your consideration draft of a proposed bill for the development of the water powers of the United States upon navigable streams, public lands and national forests. The measure was prepared under our direction by members of our departments who have had most to do with the water-power problem, and we believe it will be likely to secure extensive development of this resource, with due regard to the public interests as well as those of the developers.

It embodies the fundamental principles of several bills now pending in Congress, and an effort has been made to avoid or cure their defects. The principal features of the proposed bill are as follows:

Administration

By a commission composed of the Secretaries of War, Interior and Agriculture.

The Shields bill (navigable waters), by the Secretary of War.

The Ferris bill (public lands), by the Secretary of the Interior.

Period of Lease

The bill proposes to lease the water-power privilege for a period of not exceeding 50 years. At the end of that time the project may be (a) taken over by the United States; (b) re-leased to the original lessee; (c) leased to a new lessee.

The Ferris and Shields bills also provide for leasehold periods of not exceeding 50 years.

The attached bill proposes that at the end of the leasehold period the project may be taken over as follows: All property owned and held by the licensee then valuable and serviceable in the development or distribution of power, together with any locks or other aids to navigation constructed by the lessee, upon payment of "the fair value, not to exceed actual cost of the property taken, plus such reasonable severance damages, if any, as may be caused by the separation of said property from property valuable, serviceable and dependent as above set forth, but not taken," such value not to include any rights granted by the United States, good will, going value or prospective revenues. Further, the values allowed are not to exceed the actual reasonable cost of the property at the date of its acquisition by the lessee.

The Ferris bill provides that the United States may take over at the end of the leasehold period all property in the project to the point of distribution, upon payment of actual cost of water rights, lands and interests therein, and the reasonable value of all other property taken over, but not including franchise value, good will or other intangible elements.

The Shields bill provides that the United States may take over all the property of the grantee which constitutes part of the plant or is dependent in whole or in part upon it, upon paying to the grantee just compensation for said property, together with the cost to the grantee of the locks or other aids to navigation, no value being allowed for the rights granted by the United States for good will or anticipated profits.

REGULATION OF SERVICE AND CHARGES

The attached bill provides for regulation by the Federal Water-Power Commission of interstate power; also of power in any states where no state regulation is had. Intrastate power is to be regulated by state utility commissions, where same exist.

The Ferris bill provides for regulation of service and charges and of stock and bond issues where there is interstate transmission or in states having no commission by the Secretary of the Interior.

The Shields bill provides for the regulation of interstate power by the Interstate Commerce Commission, other power developed to be regulated by the state in which the service is rendered. No provision is made for control in those states where there is no public-service commissio

CHARGES

The bill proposes that the lessee must pay the United States reasonable annual charges, to be fixed by the water-power commission and specified in the lease, in no case to be less than 10 cents per horsepower per annum. No maximum is fixed. Where the lessee builds, maintains and operates locks or other aids to navigation, the commission may take that fact into consideration in fixing charges, also assessing against the lessee any benefits he may obtain from the construction, operation and maintenance by the United States of headwater improvements or navigation structures.

The Ferris bill provides that annual charges, measured by the power developed, shall be collected.

The Shields bill provides that payment shall be made for any lands of the United States used or occupied by the lessee, the charges to be based on the value of the lands as fixed by the Secretary of War, his discretion being limited by the requirement that the value must be ascertained by the rules in force in the state where the lands are located in proceedings where private property is sought to be taken for a public use. It also requires that the grantee shall pay the United States reasonable charges in consideration of the construction, operation and maintenance by the United States of headwater improvements.

DISPOSITION OF RECEIPTS

The attached bill provides that all receipts shall be placed in the Treasury of the United States; that 50 per cent. of the proceeds from national forests be expended in construction of roads therein; that 50 per cent. of receipts from public lands be placed in the reclamation fund; that 50 per cent. of receipts from navigable streams be expended in the maintenance and operation of dams and other navigation structures of the United States; and that all proceeds from Indian reservations shall be placed to the credit of the Indians.

The Ferris bill provides that all receipts from public lands shall be placed in the reclamation fund, and upon return to that fund, be divided equally between the United States and the states in which the development occurred.

The Shields bill provides that proceeds shall be set aside as a special fund for the maintenance of dams and headwater improvements.

We believe that some such legislation as is here proposed, if enacted, would mean the early development of a considerable portion of our water-power resources, with a resultant saving in fuel and a considerable lessening of the present demand on our transportation facilities caused by the moving of coal and other heavy fuels.

Cordially yours,

NEWTON D. BAKER.
FRANKLIN K. LANE.
D. F. HOUSTON.

THE PRESIDENT,
The White House.

Interpretations by the Boiler Code Committee

Following are the most recent interpretations by the Boiler Code Committee:

Case No. 177—Inquiry: Is the type of removable dome as shown in Fig. 13 of the Code for use on horizontal return-tubular boilers permissible under the rules of the Boiler Code, or is it necessary that this dome be attached direct to the shell with a double-riveted flange for pressures over 100 lb.?

Reply: The construction shown in Fig. 13 is considered as a steam-boiler drum and not a boiler dome, and therefore does not come under Par. 194 of the Boiler Code.

Case No. 178—Inquiry: An interpretation is requested of the application of Par. 253 to the drilling of rivet holes in crowfoot braces. Is it permissible to punch holes in the shell full size where the brace is fastened thereto?

Reply: It has been proposed to revise Par. 253 to read as follows:

253. Drilling of Holes. All rivet and stay-bolt holes, and holes in braces and lugs, shall be drilled full size or they may be punched not to exceeed ¼ in. less than full diameter for material over $\frac{5}{16}$ in. in thickness, and ⅛ in. less than full diameter for material not exceeding $\frac{5}{16}$ in. in thickness, and then drilled or reamed to full diameter.

Case No. 179—Inquiry: In the use of steel castings for the construction of locomotive boilers, what class of castings shall be used under the specifications for steel castings given in the Boiler Code?

Reply: It is the opinion of the committee that unless the Code specifically distinguishes between Class A and Class B, either class is permissible.

Case No. 180—Inquiry: Is it permissible when calculating the maximum allowable pressure on a furnace of a vertical tubular boiler, that is stay-bolted and less than 38 in. in diameter, to determine the pressure that would be allowed under Par. 239 for a plain furnace, then add the pressure which would be allowed according to Par. 199 for the supporting value of stay-bolts?

Reply: It is the opinion of the committee that individual cases and specific diameters of furnaces could be calculated either by Par. 199 or Par. 239; that is, the maximum allowable working pressure cannot be determined by a combination of the two paragraphs.

The A. S. M. E. Boiler Code is at present under revision and the committee will be glad to consider any constructive suggestions.

The following is from a reply to a communication from the Erie City Iron Works requesting the approval of the committee of a design of 148-hp. horizontal water-tube boiler:

Your inquiry of the 6th requesting the opinion of the Boiler Code Committee regarding your new 148-hp. horizontal water-tube boiler has been referred to the committee, and in reply I am directed to advise you that it has been a ruling of the committee for some time past that it will not express opinions on types of boilers, and it will therefore be impossible to comply with your request for an opinion. Yours truly, Calvin W. Rice, secretary.

Power Rate For Electrically Driven Ice Plants*

By Harry B. Joyce†

The increase in the operating cost of ice-manufacturing plants, particularly in the last year, caused by the continually rising fuel prices, the uncertainty of getting fuel at any price, together with unstable and unsatisfactory labor conditions, has forced a number of manufacturers to seek a cheaper source of adequate power and a method of eliminating, at least in part, some of their labor troubles. As electrical power supplied from central stations logically meets both of these conditions, a discussion of the various electrical rates in force in this section of the country, for the operation of these plants, seems opportune.

It is not the intention of this paper to go into the details of or explain the many advantages of electric drive for ice-manufacturing plants, but rather to attempt to present clearly the general principles and conditions of the power rates available.

PLANT MUST BE OPERATED TO FIT THE RATE

To secure the best or even a fair rate per kilowatt-hour for electrical power in most cases, it is impossible to operate the rate to fit the plant; the plant must be operated to fit the rate.

When an ice-plant owner or operator asks, "What is the rate for electrical power?" what he really wants to know is the rate per kilowatt-hour or the power cost per ton of ice. This question in the majority of cases can best be answered by "The best rate you can earn." This depends first on the way one can or will operate the plant; and secondly, on the kilowatt-hour consumption per ton of ice in the particular plant. Both of these items must be determined from the size or sizes of the compressors, the number of cans per ton, feet of pipe per ton, number and size of condensers, temperature of the condensing water, etc.

That it is possible to operate a plant so as to earn an adequate electrical rate per kilowatt-hour is proved by the many plants now operated by electricity.

Practically all the so-called refrigeration and ice-making rates are what is known as "high-tension, high-load factor, off-peak demand rates." That is, the power supplied is alternating current in excess of 2200 volts, the load factor is maintained above a certain definite value, only a limited amount of power can be demanded during certain hours of a day over a period of a year, and the cost is based either in part or wholly on the demand for power and not on the amount of power consumed. Let us therefore take up singly these various items and discuss principally the maximum demand and the electrical load factor, on which the cost of currrent per kilowatt-hour depends practically entirely when operating under this class of rate.

The United Electric Light and Power Co. defines the maximum demand, as do some of the other central stations operating in Greater New York, as the maximum fifteen-minute average demand measured during a period of one week from 12 o'clock midnight Saturday to 12 o'clock midnight the Saturday succeeding; that is, the average power demand is recorded every fifteen minutes, and the highest of these demands so recorded occurring in any week is the maximum demand for that week and on which the bill is rendered.

In other cities different methods of determining the maximum demand are in use, as are the periods of time over which the demands are effective. Buffalo, for instance, uses the highest average demand for two consecutive minutes to apply for a period of one month. In Chicago the maximum demand used is the highest thirty minutes' average demand for the off-peak rate and the highest three-minute average demand for the on-peak rate, both of these demands applying for a period of one month. This contract (Chicago), in addition to the demand charge, makes an energy charge of so much per kilowatt-hour consumed. It provides, however, that if the customer will operate his plant so as to maintain at least a 50 per cent. load factor (which will be defined later) at not less than a 200-kw. maximum demand, the cost of the current will not exceed one cent per kilowatt-hour.

The Public Service Electric Co. of New Jersey determines the maximum demand from inspection and defines it as either 70 per cent., 60 per cent. or 50 per cent. of the connected load, depending on whether this connected load is all in one motor, more than one motor under 50 hp., or more than one motor over 50 hp. Here, also, there is a service charge for each kilowatt-hour consumed and a deduction of 5 per cent. if the customer takes service at a voltage of 2400 volts or higher.

DETERMINING MAXIMUM DEMAND BY DEMAND FACTOR

This method of determining the maximum demand by what is known as the demand factor, or the ratio of the maximum demand to the connected load, is greatly to the ice manufacturer's advantage, as the demand charged is based on 50 per cent. of the connected load, while the actual maximum demand is usually greater than 80 per cent. of the connected load. I know of one plant where, during the hottest months of the year, this demand factor was as high as 135 per cent., which incidentally proves clearly the dependability of the electric motor to carry heavy overloads.

Time will not permit of discussing more of these electrical rates in detail; but practically all rates that apply to this class of service are similar in that they contain practically the same provisions and conditions.

The electrical load factor, which actually determines the cost of current per kilowatt-hour under the demand rate should not be confused with the yearly ice-load factor. The electrical load factor is the ratio of the actual kilowatt-hours consumed during the period of time over which the maximum demand is measured, to the kilowatt-hours the consumer would have used had this maximum demand been used continually during this period. That is, since the charge based on the maximum demand is the same whether or not this maximum demand is used continually, it is readily seen that the longer this demand is maintained during the period, the greater will be the consumption of current at the same cost and consequently the cheaper the current per kilowatt-hour; in other words, the higher the electrical load factor the less the cost of current per kilowatt-hour and consequently the cheaper the ice.

I might also mention that the shorter the period of time over which the maximum demand is measured, the more it is possible to maintain this higher electrical load factor. It is much easier to maintain a constant or nearly constant load, and consequently load factor, for a week than it is for a month, and it is easier to do this for a month than for a year. Central-station records show that in a properly designed and operated plant, a weekly load factor of from 85 to 93 per cent. is easily maintained; also that a monthly load factor of from 80 to 90 per cent. can be maintained during the summer months and from 60 to 80 per cent. during the winter months, while the yearly load factor will vary from 35 to 60 per cent.

Some of the central-station companies, in addition to the demand charge for this class of service, make an addition or reduction to adjust the primary rate according to the price of coal. For instance, the companies operating in Greater New York now make an additional charge or deduction of 0.035c. for each 10 per cent. increase or decrease in the price of coal above or below $3 per long ton f.o.b. New York Harbor. This additional coal charge, however, as far as I can learn, is made only by the companies who base their rates entirely on the maximum demand and make no additional charge for the energy consumed.

By the term "off-peak" as related to rates is meant that the rates are made with the provision that only a limited amount of power will be demanded during certain hours of

---

*Paper read before the Eastern Ice Association, Atlantic City, November, 1917.

†Power engineer, United Electric Light and Power Co., New York City.

the day, over that portion of the year when the central stations are carrying their greatest load. This is usually either from 4 p.m. to 8 p.m. or from 4:30 p.m. to 8:30 p.m. during the months of November, December, January and February. The power demand during this time is limited usually to from 10 to 20 per cent. of the highest previous maximum demand of the year. These values, it has been found, are sufficiently high to permit the operation of the lights and auxiliaries, and even to provide the operation of a small compressor while the large machines are shut down.

Should this specified demand be exceeded during these hours, a penalty charge is made for each kilowatt of demand in excess of that specified or a special rate is put into effect.

As far as I can learn, all these rates, with the exception of the Chicago rates, are high-tension rates; that is, the power is supplied at a voltage of 2200 or higher, and the customer must furnish his own transformers where it is necessary to have a lower voltage for the operation of any or all of his motors and, of course, for his light.

Some of the central-station companies have incorporated in their contracts such provisions as a guaranteed load factor, a guaranteed demand factor, etc., while others make an addition or deduction if the line power factor is below or above a certain definite value. I think it has been shown that it works no hardship, but that the ice manufacturer must maintain as high an electrical load factor and demand factor as is possible to earn a reasonable rate. As for a reduction in rate for maintaining a high power factor, this can easily be done by the use of synchronous motors on the compressors, which will permit of maintaining practically any power factor desired.

SUMMARY

Let me summarize what I believe to be the safest and most accurate way to predetermine or estimate the power cost per ton of ice when it is decided to change to electric drive. First determine the number of kilowatt-hours necessary per ton of ice and what changes will be necessary to operate your plant at a constant or nearly constant load for the time over which the maximum demand will be measured. Then have the central-station representative of the district advise what the average load factor is for similar plants operating in the neighborhood, also the cost of current per kilowatt-hour at this load factor under the rate according to which your plant will operate.

I believe that many, particularly those who are operating plants in the larger cities where central-station electric power is available, will be figuring on this question within the next year or two. At this time last year, there was not an electrically operated ice-manufacturing plant on Manhattan Island. Today there is one in operation, five plants being changed over from either steam- or oil-engine drive, and one new plant in the course of erection.

If it is my privilege to attend this convention next year, I hope to be able to present some very interesting figures on the operation of these plants, all of which are different not only in capacity, but also in the number of cans used per ton, feet of pipe per ton, size and number of condensers, some using cooling towers, some wells, and others river water. I hope at that time to be able to show that although all these factors affect in one way or another the necessary kilowatt-hours per ton of ice, a high load factor and consequent low cost of current per kilowatt-hour can be maintained, under all of the foregoing conditions, if the plants are properly operated.

Message to German Business Men

The Chamber of Commerce of the United States has sent to its members a referendum which is designed to ascertain whether American business men desire to notify German business men that they will not trade with them after the war unless the German government is made responsible to the German people. The National Chamber announces that 500,000 American business men are now voting on this question through national commercial organizations that are members of the National Chamber.

The referendum is the suggestion of the Boston Chamber of Commerce, and if it is adopted by the members of the National Chamber, it is hoped to communicate its result to German business men through international chambers of commerce and through German business men who are now visiting Switzerland, Holland, Denmark, Sweden and other neutral countries. Announcement by the National Chamber in regard to the referendum says: "The message cannot fail of its purposes, as Germany cannot hope for years to come to reëstablish satisfactory trade relations with Great Britain, Italy or France."

The message on which the vote is being taken is as follows:

Whereas, The size of Germany's present armament and her militaristic attitude have been due to the fact that her government is a military autocracy, not responsible to the German people; and

Whereas, The size of the German armament after the war will be the measure of the greatness of the armament forced on all nations; and

Whereas, Careful analysis of economic conditions shows that the size of Germany's future armament will fundamentally depend on her after-war receipts of raw materials and profits from her foreign trade; and

Whereas, in our opinion the American people for the purpose of preventing an excessive armament will assuredly enter an economic combination against Germany if governmental conditions in Germany make it necessary for self-defense; and

Whereas, We believe the American people will not join in discrimination against German goods after the war if the danger of excessive armament has been removed by the fact that the German government has in reality become a responsible instrument controlled by the German people; therefore, be it

Resolved, That the Chamber of Commerce of the United States of America earnestly calls the attention of the business men of Germany to these conditions and urges them also to study this situation and to coöperate to the end that a disastrous economic war may be averted and that a lasting peace may be made more certain.

Economizer Explosion Kills One Man

By the explosion of an economizer at the Remington, N. Y., "Short Line" power plant, one man was killed and the electric power and lighting circuits supplied by the plant were put out of service. The accident occurred a little after 10 o'clock on the night of Dec. 28. According to the newspaper account, the cause of the explosion is not known. It is stated, however, that earlier in the evening the power was shut off at the plant for more than an hour because of a leak in a valve on the economizer. That was repaired and electric service was resumed, when shortly afterward the economizer exploded.

The man who was killed was a water tender, and it is assumed from the position in which he was found that he was quite close to the economizer when the explosion occurred, as he was buried beneath the wreckage. One of the firemen in the boiler room was taken to the hospital.

Two of the seven boilers were damaged. These boilers were housed in a wooden frame building, the end of which was blown out and the boiler house more or less wrecked. Details of the accident will be published as soon as the facts can be obtained.

Christopher W. Levalley

Christopher W. Levalley, founder and chairman of the board of directors of the Chain Belt Co., died suddenly of heart failure at his home in Milwaukee, on Friday, Jan. 4. He was born at Manchester, Conn., in April, 1835, receiving his education in the schools there. When 14 years old he moved to Hartford, Conn., where he served an apprenticeship in a machine shop. At the outbreak of the Civil War he enlisted in the army. Following the war he went to St. Paul as superintendent of the St. Paul Harvester Co., later becoming general manager. It was at this time that he saw the necessity of a positive drive for harvesting machinery, and in 1891 he moved to Milwaukee, where he established the Chain Belt Co. In 1907 Mr. Levalley conceived the idea of driving a concrete mixer with a steel chain and using a cast semisteel drum. These ideas were incorporated in what was known then as the Chain Belt Mixer, but which name has since been changed to Rex Mixer.

Mr. Levalley would have been 83 years old in April had he lived. From 1891 until 1916 he was president and general manager of the Chain Belt Co. In 1916 he was elected chairman of the board of directors and held this position up to the time of his death. He was also interested in the C. O. Bartlett & Snow Co., of Cleveland, and the Federal Malleable Co., of Milwaukee. He was a donor of many gifts to charitable institutions and only within the past year gave $100,000 to the Milwaukee Foundation.

Wartime Lubrication Economy

An example of lubrication economy is that of a large, well-equipped and well-managed plant in Boston. During the year preceding an investigation to cut the costs, the plant used 18,500 gal. of various oils with a total lubrication cost of $4425. Under the system used barrels of oil were distributed through the plant, and several were found to be leaking. The remedy was the construction of a central oilhouse containing metal tanks provided with key faucets. Much loss was also due to wiping up of engine frames and floors with waste, then thrown away or burned. To check this loss, an oil- and waste-saving machine was installed. This reclaimed considerable oil, and the waste could be reused many times. Cost of lubrication dropped from $4425 to $2570 within one year, a saving of almost 42 per cent.—*The Wall Street Journal Straws.*

What Power Did for a Dry Dock

To operate the dock of the New Orleans Dry Dock and Shipbuilding Co. by hand required the services of 64 men at an average cost of 25c. per hour per man, and the best time made was two hours for a small vessel. The dock has just been equipped by S. J. Stewart with eight motors, which make use of the old-style sucker pumps formerly operated by hand, by the use of which they are now able to make a lift in half an hour with the consumption of about $3 worth of current.

New Publications

THE DETERMINATION OF ABSOLUTE VISCOSITY BY SHORT-TUBE VISCOSIMETERS. Technologic paper, No. 100. Published by the Bureau of Standards, Washington, D. C. Size, 7 x 10 in.; 55 pages.

This publication reviews briefly the literature relating to the determination of viscosity and gives the results of further experimental work that has been done. The conclusion is reached that water is not a suitable liquid to use in finding the relation between the viscosity and the time of discharge for short-tube viscosimeters, and that Ubbelohde's equation and all others based on it are seriously in error. The paper is now ready for distribution, and those interested may obtain a copy by addressing a request to the Bureau.

Miscellaneous News

Regulation of Coal Exports during 1918 announced by the Fuel Administration limits shipments strictly to war uses.

A Boiler Flue Blew Out at the Barnet leather plant, at Little Falls, N. Y., on Dec. 31, severely scalding two men who were in the boiler room at the time of the accident.

The Boiler of a Pennsylvania R.R. engine attached to a freight car exploded at Metuchen, N. J., on Jan. 8, seriously injuring two men, one of whom died a few hours later in a hospital.

The Power House and Machinery of the municipal light and water plant at Marlington, W. Va., were destroyed by fire on Jan. 8. The fire was discovered over the boiler room. The cause is unknown.

A Boiler Explosion wrecked the Home Laundry at Delaware, Ohio, on Jan. 8 and decapitated the proprietor, T. E. Fox. The explosion occurred when Fox turned cold water into the empty tubes of the boiler, under which a hot fire was burning.

Flywheel Explosion at Hawarden, Iowa—Operation of the Hawarden, Iowa, municipal electric plant was interrupted for a time when the flywheel of one of the engines driving a generator exploded on the night of Jan. 2. Damage to the building was confined mostly to the walls opposite the flywheel and to the roof above it. It will cost about $4000 to repair the damage done to the engine and buildings. Temporary service was obtained from a reserve engine as soon as it could be put in running order. Fortunately, no one was injured.

Obituary

Malcolm Alexander, formerly superintendent of the old Brooklyn Union Gas Co., with which he was connected for thirty years, and later in the harbor transportation business, died at his home in Brooklyn on Jan. 11, at the age of 88 years. He was a native of Glasgow, Scotland.

Personals

E. B. Craft, W. F. Hendry and E. H. Colpitts have been appointed assistant engineers of the Western Electric Co.

Franklin T. Chapman, formerly connected with the Olympian Motors Co., of Pontiac, Mich., is now assistant general sales manager of E. F. Houghton & Co., Philadelphia, Penn.

Harry V. Hunt has resigned as superintendent of the Hooven, Owens, Rentschler Co., at Hamilton, Ohio, to accept the position of general superintendent of the Consolidated Press Co., at Hastings, Michigan.

J. S. Pandiani, formerly manager of the meter and supply department of the Italian Westinghouse Co., is now the Italian trade representative of the Esterline Co., of Indianapolis, Ind., with headquarters at Via Mario Pagano 27, Milano.

Russell T. Gray, formerly advertising manager of the Haynes Automobile Co., and more recently secretary of the Shuman Advertising Co., has opened an office in the First National Bank Building, Chicago, as an advertising engineer. Advertising service will be rendered a limited number of clients in the technical field. Technical advertising in trade papers and magazines as well as all forms of engineering catalogs and direct-by-mail advertising will be handled.

Engineering Affairs

The National Association of Stationary Engineers, No. 9, of Atlantic City, will hold its sixth annual banquet and entertainment at the Wiltshire Hotel, on Saturday evening, Jan. 26.

The Boston Section of the A. S. M. E. will give a reception to Charles T. Main, the new president of the American Society of Mechanical Engineers at the Engineers' Club, Boston, Mass., Tuesday evening, Jan. 22. This will be one of the big events of the Boston Section this season. Prof. Lionel S. Marks will speak briefly on the career of Mr. Main. H. C. Balch, of the Boston "Transcript," just back from France, will speak on "Engineering at the Front," as he saw it.

The Association of Iron and Steel Electrical Engineers has announced the following meetings: The Cleveland Section on Jan. 26, subject not yet announced. The Philadelphia Section on Feb. 2, at which H. G. Steele, of the Pittsburgh Transformer Co., will speak on "Mill Type Transformers." The Pittsburgh Section will meet on Feb. 16 at the Hotel Chatham, at which David L. Lindquist, chief engineer of the Otis Elevator Co., will present a paper on "A. C. and D. C. Skip by Hoists."

The Aldred Lectures at Johns Hopkins University—Through the generosity of J. E. Aldred there has been founded in the Department of Engineering of Johns Hopkins University, of Baltimore, a course of lectures on "Engineering Practice." The lectures will deal with the practical phases of engineering problems, rather than with theory, and will consist of three lectures each on general subjects in civil, electrical and mechanical engineering. They are given on Wednesday evenings at 8 o'clock, in the auditorium of the Civil Engineering Building. Those of particular interest to "Power" readers are "Steam-Electric Power Plant Design," given on Jan. 16 by A. S. Loizeaux, electrical engineer of the Consolidated Gas, Electric Light and Power Co., of Baltimore; and "Coal and Its Combustion in Boiler Furnaces," by E. G. Bailey, president of the Bailey Meter Co., Boston, to be given Mar. 13. The lectures are open to the public.

New York Engineers Granted Charter—The New York Chapter of the American Association of Engineers was established on Wednesday evening, Jan. 16, at the Hotel McAlpin, when the charter granted by the national organization was formally presented by President Edmund T. Perkins. The keynote of the meeting was sounded by Mr. Perkins, the principal speaker, with the subject, "The Engineer's Relation to Society." He urged the men to broaden their social and civic activities and to pay more attention to the human equation in engineering. Alexander Potter complimented the association on its national success with the problems relating to the human and business side of the engineering profession. A. H. Krom, general secretary of the A. A. E., gave a summary of the activities of the national organization and urged the members to promote the work and coöperate with all technical societies as well as to acquaint engineers with the fact that this is a business organization in a field of its own and which conflicts with none. E. J. Mehren, editor of the Engineering News-Record; S. J. Stone, A. C. Davis and others put forward valuable suggestions during the discussion. The New York office is at 220 West 42nd St., and the officers are: R. H. Vanderbrook, chairman; I. L. Birne, secretary.

Trade Catalogs

Link-Belt Silent Chain for Rubber Mill Machinery. Link-Belt Co., 39th St., Stewart Ave., Chicago, Ill. Book No. 299. Pp. 24; 6 x 9 in.; illustrated.

"Hydro" Gas Meters. Bacharach Instrument Co., Pittsburgh, Penn. Catalog E. Pp. 12; 6 x 9 in.; illustrated. This contains information on the various methods employed in the measuring of gases and shows the application of these meters to producer plants, gas works, etc.

How Anyone Can Make a Jointless, Gastight Furnace Lining is the title of a booklet issued by the Betson Plastic Fire Brick Co., Rome, N. Y., showing how "plastic fire-brick" made by this concern is used in forming one-piece linings for steel boiler furnaces. Pp. 16; 3½ x 6 in.; illustrated.

Smooth-On Instruction Book No. 16. Smooth-On Manufacturing Co., Jersey City, N. J. Pp. 16; 3½ x 6 in.; illustrated. This describes various cements for repairing breaks or leaks in iron pipes, castings, etc., and contains the standard sizes of Smooth-On coated corrugated gaskets for flanged pipes from 2 in. up to 26 inches.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows.

ANTHRACITE

	Circular[1]		Individual[1]	
	Jan. 17, 1918	One Year Ago	Jan. 17, 1918	One Year Ago
Buckwheat	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Jan. 17, 1918	One Year Ago	Jan. 17, 1918	One Year Ago
Clearfields	....	$3.00	......	$4.25—5.00
Cambrias and Somersets	....	3.10—3.85	.....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4 as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.60 †Water coal

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Jan. 17 1918	One Year Ago	Jan. 17, 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$7.00—7.25
Buckwheat	4.30—5.00	2.75	5.50—6.00	6.50—7.00
Rice	3.75—3.95	2.20	4.50—5.00	4.50—5.00
Barley	3.25—3.50	1.95	3.50—4.00	3.25—3.50
Boiler	3.50—3.75	2.20	....	......

Bituminous smithing coal, $4.50—5.25 f.o.b.
Quotations at the upper ports are about 5c. higher

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide		Independent
	Jan. 17, 1918	One Year Ago		Jan. 17, 1918	One Year Ago
Buckwheat	$3.15-3.75	$2.00	$3.75	$2.90	$4.15
Rice	2.65-3.65	1.25	3.65	2.15	3.35

Williamson-Franklin rate St. Louis, 87½c.; other rates, 72½c.

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump and Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba	2.40	2.65	2.15

Government figures.

PROPOSED CONSTRUCTION

Calif., Los Angeles—The Nevada-Calif. Power Co., Riverside, plans to build about 300 miles of voltage line. About $300,000. C. O. Poole, Riverside, Ch. Engr.

D. C., Wash.—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at various Navy Yards under Schedule No. 1653, 30 sets of motor generators.

Ga., Waynesboro—City plans extensive improvements to its electric-lighting plant, including the installation of one 200-hp. boiler, and one 100-kw., 3-phase, 60-cycle, 2300-volt generating unit directly connected with a switchboard, complete. J. C. Andrews, Supt.

Ill., Chicago—The Lincoln Park Commissioners plan to install a 500-kw., 3-phase, 2300-4000-volt turbo-generator for heating system. C. H. Shepherd, Electrical Engr.

Iowa, Emmetsburg—The Northern Iowa Gas and Electric Co. plans to extend its electric transmission line from here to Dickens. R. J. Mullins, Mgr.

Kan., Sabetha—The City Council plans to change the equipment of the entire electric-lighting plant from single to 3-phase system. C. A. Darby, City Engr.

Ky., Guthrie—The South Kentucky Power Co. plans to build an electric transmission line from here to Lebanon, Tenn. A. F Trimble, Mgr.

La., Kenner—City plans to issue $10,000 bonds for improvements to its electric-lighting plant. P. Felix, Mayor.

Md., Rising Sun—City has sold $8000 bonds and plans to improve its electric-lighting plant with the proceeds.

Mass., Cambridge—The Cambridge Electric Light Co. plans extensive improvements including the installation of a 12,500-kw. turbine, two 600-hp. boilers, an ash-handling system and the extension of its switchboard. W. E. Holmes, Newton, Gen. Mgr.

Mass., Gardiner—The Gardner Electric Light Co. plans to install an additional 1500-kw. bank of transformers. C. A. Ware, Mgr.

Mass., Hudson—The Town plans to install a new 600-kw. turbine with a condenser and an additional boiler in its electric-lighting plant. G. A. Brothers, Mgr.

Mass., Pittsfield—The Pittsfield Electric Co. plans to install a 2500-kw. General Electric turbo-generator and two 520-hp. Babcock & Wilcox boilers. W. A. Whittlesey, Supt.

Mich., Sturgis—The Board of Public Works plans to install a 500-kw. auxiliary generating unit. J. S. Flanders, Mgr.

Mo., Cameron—The City Council plans to improve its electric-lighting plant.

N. Y., New York—The Electric Reduction Co., 50 East 41st St., has increased its capital stock from $100,000 to $200,000; the proceeds will be used for additions and improvements.

N. C., Southern Pines—J. T. Patrick is in the market for second-hand electrical machinery in good condition, from about 25 to 50 hp., for water-power development.

Okla., Chandler—The Chandler Electric Co. plans to build a new power house and install equipment. H. G. Stettmund, Jr., Mgr.

Okla., Hooker—City plans to issue bonds for the erection of an electric-lighting plant to replace the one which was destroyed by fire. Loss, $22,000.

Wash., Seattle—The City Council plans to build a substation for the Light Department on B 166, Gilman Park addition. About $20,000. A. H. Dimock, City Engr.

Wis., Amherst—The Amherst Electric Service Co. recently incorporated, plans to build an electric-lighting plant. B. E. Dwinnell, interested.

Wis., Sheboygen—The Badger State Tanning Co. is having plans prepared by Juul & Sixta, Arch., 805 North 8th St., for the erection of an addition to its power house.

Wis., Stebbinsville—The Porter Electric Line Co. recently incorporated, plans to develop the water power and furnish electricity to the rural district here. F. Miller, Pres.

Ont., Port Colborne—A. E. Augustine, Box 116, is in the market for a 15-hp electric motor with starter.

Ont., Toronto—The Swift Canadian Co., Keele St., is in the market for a 50-hp. locomotive-type boiler.

Ont., Trenton—The Hydro-Electric Power Commission, Toronto, plans to build a transmisison line through the towns of Picton, Wellington and Bloomfield in Prince Edward County; also a 4000-volt transmission line from Bloomfield to Wellington, for which 2 substations will be built. F. A. Jaby, Ch. Engr.

Ont., Windsor—The City Commissioners plan to install 2 new electrically driven pumps in its pumping plant.

Que., Valleyfield—The Montreal Cotton Co. plans to rebuild its power plant which was recently destroyed by fire. Loss $100,000.

---

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, JANUARY 29, 1918 No. 5

Fooling One's Self

Contributed by R. B. DALE

THE EASIEST PERSON in the world to fool is one's self. There is a very good, logical reason for this. As a matter of fact, most of us believe just what we want to believe. The engineer, of all men, because of his training and experience, should be more proof against this mistake than others. The engineer learns to base his decision on facts. Business life today presents some very unpleasant awakenings for the man who bases his convictions on impressions rather than on facts and principles. The engineer marshals the facts together, estimates their value and reasons logically therefrom. Such a man is not likely to be in the wrong very often.

The Irishman who took off his coat, rolled up his sleeves and stated that he would like to see the man who could convince him that he was wrong, evidently was not very anxious to be convinced. Fooling one's self is a popular game. The man who really wants to know whether or not he is fooling himself uses every possible means to test his ideas. He who could lick the big Irishman would not necessarily prove that the Irishman was in the wrong, but the premise would be in that direction. Because the expert scorns your favorite idea, it does not necessarily follow that you are entirely wrong, but it does mean that you must put it to the most rigid test.

THE OTHER DAY a man put a little white powder in a pail of water and then threw the water on some coal that he put in the furnace. He wanted the dope to make good. He wanted it so badly that he did everything in his power to create favorable conditions. He had a better fire. He made less smoke. He made more steam with less coal. He thought it was the dope that caused the improvement. As long as the white powder lasted that fireman had wonderful results, but as soon as it was gone he unconsciously went back to his old, slipshod methods of firing. That man was fooling himself. He would have done even better without the dope had he taken the trouble to improve his methods.

Another man had an idea that he could get remarkable efficiency out of a boiler plant by preheating the feed water in a separately fired heater. He wanted his scheme to succeed, an therefore he used every means in his power to make it succeed. He created favorable furnace conditions. He watched the apparatus with great care and directed its entire operation. He got increased efficiency, but he did not stop to consider where it came from. Experts told him that if he had used the same careful methods, he would have gotten similar results, heater or no heater. He was fooling himself.

DO YOU BELIEVE the methods in your plant cannot be improved upon? Do you think that you cannot get more power with less coal than your records now show? That's where you fool yourself. There are no methods so good that they cannot be made better. It has been asserted that about one-quarter of the coal burned is wasted. How much do you contribute to that waste?

Are you doing the best that can possibly be done with the facilities and equipment at hand? Of course you think you are and that is fine, but how about improving the equipment? The "old man" won't be convinced. That's where you fool yourself. Business men were never so eager to install coal-saving and money-saving equipment as they are today. Have you tried to put the matter before him in a clear-cut, logical way, and have you proved to him what savings might be made with the new facilities?

Are you fooling yourself?

Turn the searchlight of investigation on your own methods. It will pay.

Condensers with Seventy-Foot Water Level Variation

By F. R. Brosius

These condenser wells are five in number. The intake well is 86 ft. deep and 60 ft. diameter. Two condenser wells will contain all the condensing equipment; each is 84 ft. deep and 68 ft. diameter. The two discharge wells are 17 ft. diameter. These wells are necessarily deep owing to the fluctuating water in the Ohio River, which is about 70 ft. between extreme low- and extreme high-water levels.

THE most interesting and unusual feature of the West End Power Station of the Union Gas and Electric Co., of Cincinnati, Ohio, which is now nearing completion under the supervision of Sargent & Lundy, is the type of substructure construction adopted to assure a satisfactory supply of condensing water under unfavorable conditions and to support the great weight of the building and equipment on unstable ground.

The site chosen for the station was the location of the company's old artificial gas plant, which was abandoned when natural gas was brought to Cincinnati and which had to be torn down before the new station could be built. This location is on the north bank of the Ohio River, which at this point fluctuates in level about 70 ft., due to spring floods in the valley above Cincinnati. At the extreme high-water mark, the gas-works tract was covered with six to eight feet of water. The ground consists of a fill of cinders, slag, etc., about fifty feet deep, resting on native sand and gravel at an elevation of approximately 440 ft.—making the surface approximately 490 ft. above sea level.

FIG. 1. CONDENSER WELLS BELOW TURBINE ROOM

Obviously, under such conditions the conventional arrangement of the turbine-room equipment would not be feasible, because of the excessive lift of condensing water that would be required under normal operating conditions—that is, at all times except during flood stage of the river—if the equipment were placed high enough to be safe from water at all times. To overcome this obstacle, the construction described in the following paragraphs was used.

The building is constructed with a river wall tangent to a chord of the harbor line drawn to the property line, the harbor line at this point being an arc of a circle of 4077.56 ft. radius. The turbine room is on the river side of the building, with its basement floor at an elevation of 502 ft. 15 in. above sea level and the main turbine-room floor at an elevation of 516 ft. The boiler room is north of the turbine room, with the basement floor 504 ft. and the main floor 522 ft. above sea level.

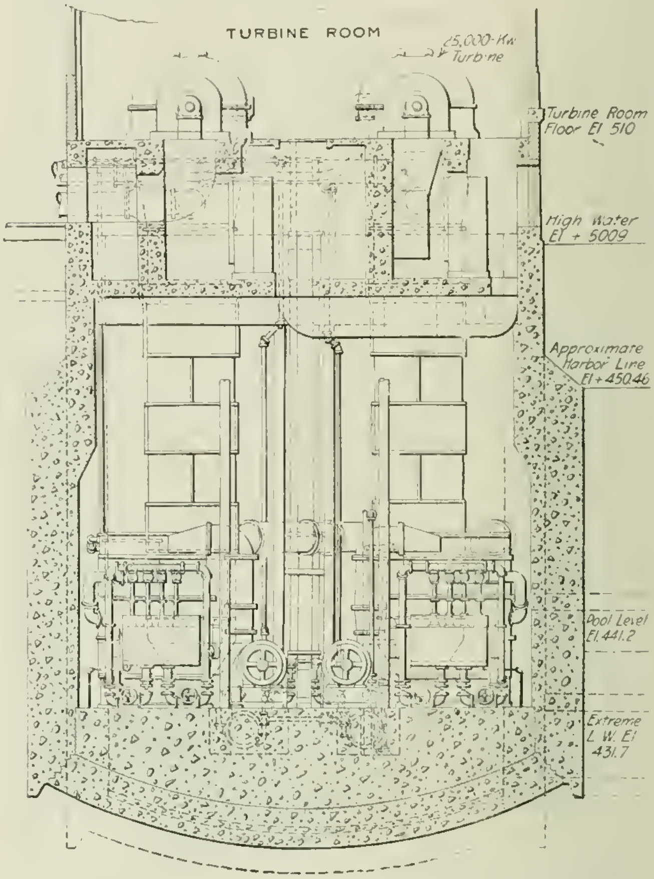

FIG. 2. CROSS-SECTION OF THE WEST CONDENSER WELL

To provide for water, five wells were sunk below the turbine room, arranged as shown in Fig. 1. The center one is the intake well; on either side of it is a condenser well, and between each condenser well and the intake well there is a discharge well, Fig. 3. Tunnels run from the river into the intake well and from the discharge wells into the river bed.

The intake well is 86 ft. deep from the basement floor to the well floor and is 60 ft. inside diameter. This depth brings the bottom of the well to a level approximately 16 ft. lower than the extreme low-water mark, assuring a plentiful supply of water under all river conditions. It has solid reinforced-concrete walls, 6 ft. thick, from the bottom of the well to the basement floor. This well contains a heavy bar-iron grill to remove the coarser débris floating in the river, and behind the grill traveling screens remove any rubbish not caught by the grill. A set of stationary screens is also provided to supplement the traveling screens when necessary. The intake tunnel leads into the bottom of this well. It is 163 ft. long from the river bed to the wall of the well and is 25 ft. high by 10 ft. wide inside, with reinforced-concrete walls 2 ft. 6 in. thick. The mouth of this tunnel opens into the river on the slope of the harbor line, avoiding any projection into the river, and is supported on piling to prevent any damage due to undercutting by the river. The river bed for a radius of 25 ft. from the tunnel mouth is riprapped to prevent erosion.

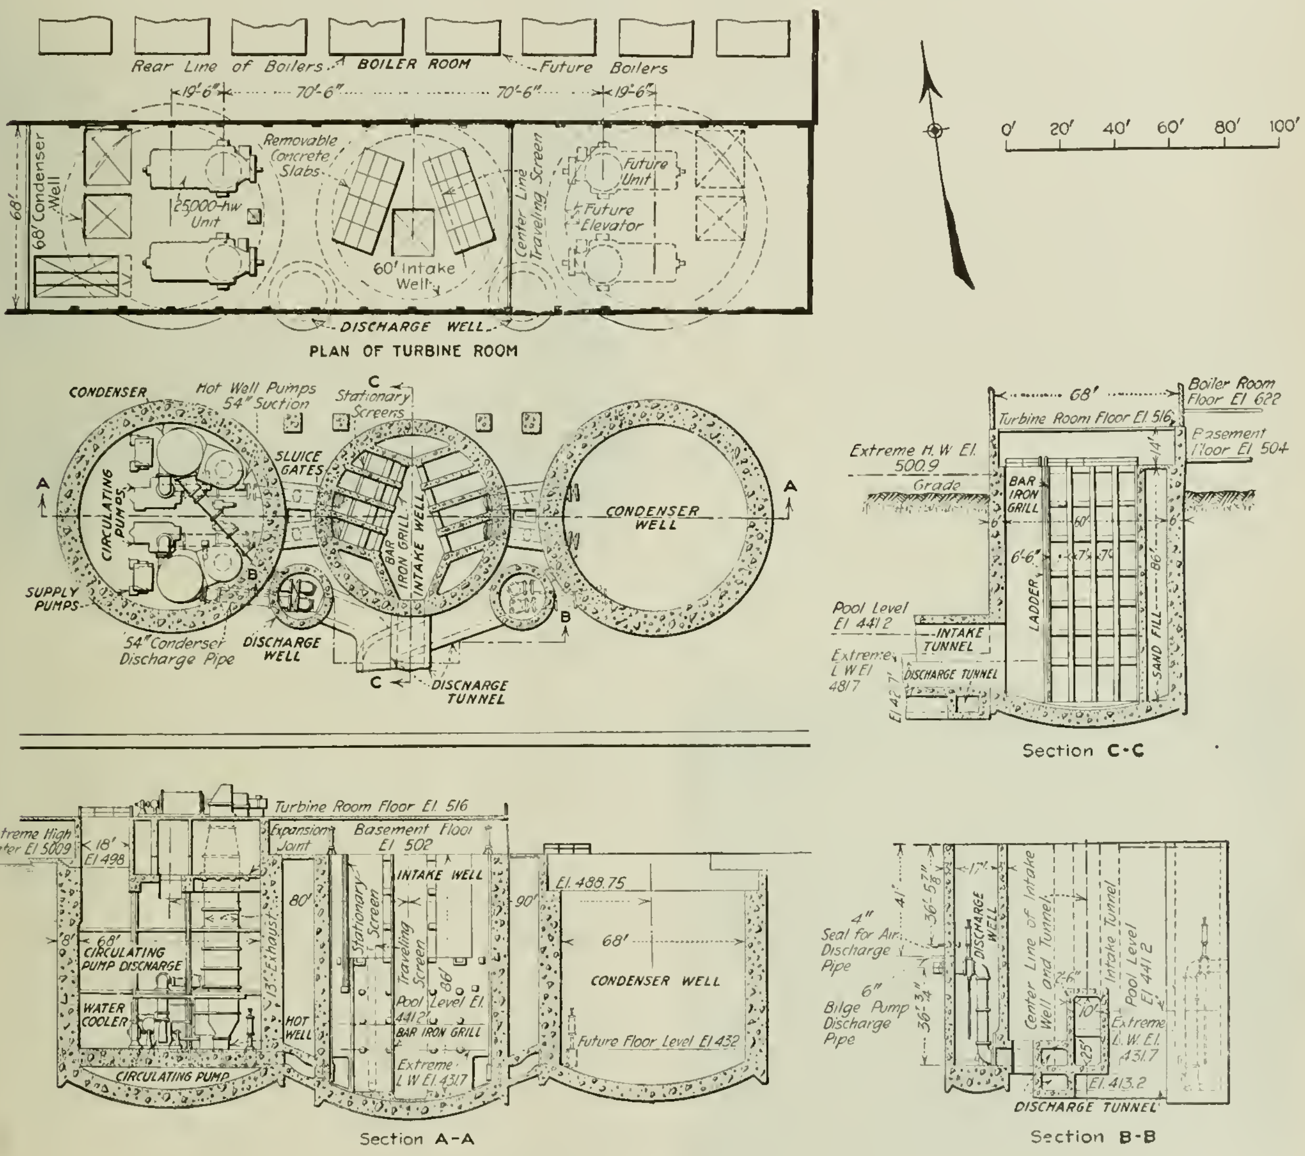

FIG. 3. PLAN AND SECTION OF CONDENSER AND INTAKE WELLS

The condenser wells are each 68 ft. inside diameter and 84 ft. deep from the basement floor, and are watertight to a point above the flood stage of the river. The floors of these wells are of solid concrete 16 ft. thick at the walls and 30 ft. thick in the center, and the walls are of reinforced concrete 8 ft. thick. The west condenser well only is used for the initial installation of two 25,000-kw. turbo-generators, Fig. 2, the east well being reserved for a future increase in the capacity of the plant. This well contains all the condensing equipment for the two turbines, which exhaust through pipes 13 ft. in diameter and 62 ft. long into vertical condensers, each with 52,000 sq.ft. of cooling surface. These condensers and all auxiliaries and sump pumps are placed on the floor of the well, which is 68 ft. below extreme high water.

The discharge wells are 17 ft. inside diameter, with walls 3 ft. thick. As with the condenser wells, only the west discharge well is used for the first installation. Two discharge pipes from the west condenser well enter the discharge well at the level of the top of the condensers and drop to the bottom of the well, where they are sealed into the end of the west branch of the discharge tunnel. Two tunnels, 6 x 10 ft. inside, one from each discharge well, meet at a point south of the intake well and below and west of the intake tunnel, and form a single discharge tunnel 10 x 10 ft. inside, with walls 2 ft. 6 in. thick, which extends 214 ft. in a downstream direction from the intersection, into the river. The construction of the mouth of this tunnel is similar to that of the intake tunnel.

In the operation of the plant condensing water will be drawn through the intake tunnel into the intake well, where all foreign matter will be removed from the water by a grill and screens. It will then pass through 54-in. suction pipes extending from the intake well through the floor of the condenser well to the circulating pumps, then through the condensers and in 54-in. discharge pipes to the discharge well, and back into the river through the discharge tunnel. The entire water system from the point where the water enters the suction pipes in the intake well to where it leaves the discharge tunnel in the river is a closed siphon, thus making any lift of water by the circulating pumps unnecessary and making their only duty that of overcoming friction in the piping and condenser tubes.

The method used for sinking the three larger wells is of interest in itself. An excavation about ten feet deep and with a diameter greater than that of the well was made on the site of the well, and a circular steel shoe, or cutting edge, made of 12-in channels laid flat with plates riveted to the outer flange, with its outside diameter the same as that of the well to be sunk, was set up on the bottom of the excavation. Concrete forms were then set up on the shoe, arranged for concrete the width of the shoe at the bottom and then by 12-in. steps reaching the full thickness of the wall. Concrete was then poured in to make a ring 12 ft. high. When this had set, the forms were removed and the excavation continued inside the ring, allowing the ring to sink of its own weight. By continuing this process of alternately building the ring higher and then excavating and allowing it to settle, the well was sunk to the desired depth. When this had been reached, water was let in the well and the inverted dome-shaped bottom concreted under water by the use of a submarine bucket. Then, when this had set thoroughly, the water was pumped out and the remainder of the concrete bottom put in. The discharge wells were started in the same way as the larger wells, but were finished as closed caissons under air pressure. Figs. 4 and 5 are views of the interior and exterior of the wells respectively.

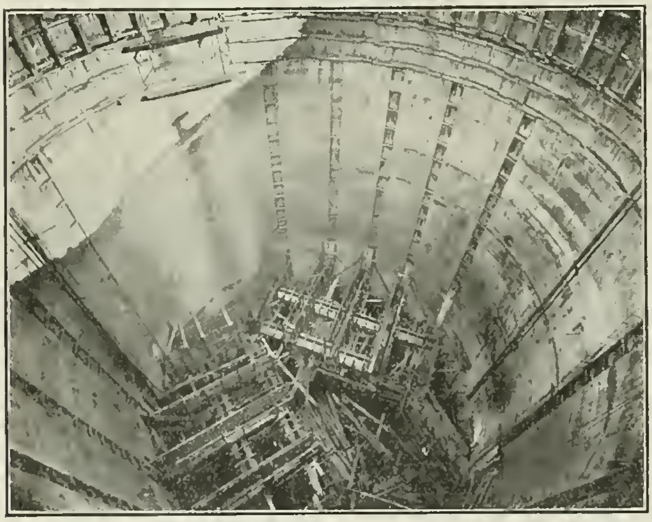

FIG. 4. INTERIOR VIEW OF ONE OF THE WELLS

Part of the weight of the turbine room rests on these wells. The rest of the weight of the building and equipment is supported by nine rows of concrete piers, which were sunk to firm native bed gravel, at depths varying from sixty to eighty feet below the surface of the filled ground.

In this article only a description of the system of wells has been attempted, as a detailed story of the entire plant will be published when it reaches completion. The writer acknowledges his indebtedness to the engineers of Sargent & Lundy, who planned the station, and of the Foundation Co., who built the plant, for their coöperation and assistance in preparing this article, and to C. R. McKay, consulting engineer for the Union Gas and Electric Co., for the photographs reproduced herewith.

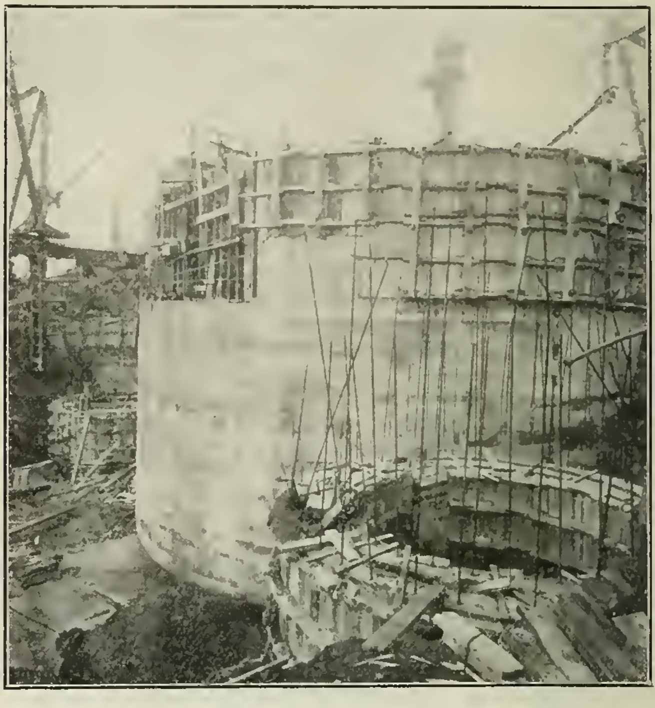

FIG. 5. EXTERIOR OF WELLS, SHOWING FORMS IN POSITION

Abstracts from an Engineer's Letters

Dear Friend—Replying to your inquiry as to whether "the design of a boiler joint can be brought out so a common, everyday engineer and fireman can make it out without the use of so many letters and combinations of letters that the whole matter is befogged," I will say of course it can, but the use of letters is more convenient when you get accustomed to them. In justification of the use of letters and their combination into groups, it may be said that almost every engineer or fireman does exactly the same thing in his daily conversation, where no effort is expended in writing it out and no valuable space is used up on a printed page. It is simply a short mode of expression. He hails his mate as "Bill" instead of Mr. William Muldowney, for example. The only thing necessary is a mutual understanding of just who is meant when "Bill" is called; for if there are others of the same name, there must be some other distinguishing name or letter and in many places the true initials are used, as "Hello, B. M."

One of the first expressions met with in the discussion of the boiler and boiler joint is the "tensile strength" of the plates or the material entering into boiler construction subjected to tension. If, however, the expression is to be frequently used, the initial T (sometimes TS) is used instead of the full name, as in the case of "Bill." Of course it must be known what the term tensile strength (T) means or stands for, but that is easy. If a bar of any material of convenient length is stressed (pulled) in the direction of its length with sufficient force, it will of course pull apart, and with means of measuring the extent of the force applied (pounds pull) the total force is known. An ordinary spring balance may be used to test the force necessary to break a small cotton cord and be satisfactory for that particular cord, but for comparison with cord of another material the size (thickness) of each must be known, so in testing the "T" of iron and steel the standard unit of one square inch has been adopted.

Therefore T is understood to represent the stress in pounds required to pull apart a bar of one inch square section, or its equivalent, which may be a bar one-half inch thick and two inches wide or any such combination of dimensions. Furthermore, the test piece does not necessarily have to be equal to one square inch so long as its actual measurement is known, for if it equals one-half a square inch (not, however, one-half inch square, or measuring one-half inch on each face, which would be only one-fourth of a square inch) and withstands one-half the strain that a bar one inch square does, their T is the same. If the plates from which a boiler is made are not good (low T), evidently its ability to resist the steam pressure which tends to pull the fibers apart will be correspondingly less.

Taking, for an experiment in the design of a riveted joint, a couple of strips of plate 10 in. wide and ½ in. thick and stamped T 60,000, the solid plate would be expected to pull apart at $60{,}000 \times 10 \times \frac{1}{2} = 300{,}000$ lb., since there are 5 sq.in. area times (T) 60,000. But since it is necessary to drill holes in the ends to joint the pieces together, it is obvious that the total strength of the sample will be correspondingly less. The question then arises, How many holes will it be necessary to drill and what size? If five 1-in. holes are drilled in a line, then one-half of the width of the sample is cut away and the "net section of the plate" is only 50 per cent. of the original, and therefore the joint at best can only be one-half, or 50 per cent., as strong as the plate. Besides that, How about the rivets? Suppose rivets made of lead are used, the joint will not stand much of a pull because the lead will shear off easily. A quality, then, that the rivet material should possess is resistance to shearing action. This is designated as S (just another fellow's initial), so S = shearing strength and its value is anywhere from 35,000 to about 42,000 lb. per sq.in. cross-sectional area as before, only the strain is across the bar instead of endwise. Suppose, then, that the rivets used are square and each is one inch square and $S = 37{,}500$, how many will be required to equal the strength of the sample already drilled with five holes? Answer: $300{,}000 \div 37{,}500 = 8$ rivets. If the 8 are put in a row there will be a loss of $\frac{8}{10}$ of the original width of the sample, so they must be placed in two or more rows or other means used to improve conditions, and this leads a step farther.

A joint made by lapping one edge of the plate over the other serves well enough for some purposes, but the strain tends to kink the plates at the weakest point, which is at the rivet holes, therefore it is best to bring the plates edge to edge and to use a narrow "strap" to join them, and it is also advantageous to use such a strap on both sides of the plates so that the rivets will extend through both straps and the plate between. This is termed a "double butt-strap joint," and incorporating the statement of the type and number of rows of rivets gives a full description of the joint, such as "triple-riveted double-strap joint," etc.

When double-butt straps are used, the rivet will tend to shear at two points of its length instead of one, therefore it will withstand a greater strain, and this has been variously stated as 1¾ to 2 times the single shear. The A. S. M. E. Boiler Code Committee has adopted the value as twice S (stated as $2S$ or SS by different writers) for rivets in single shear, and this is being generally adopted.

To get back to the experimental joint, then, four rivets in double shear will do as well as the eight in single shear or will equal the T of the sample, but this still leaves the joint strength only 60 per cent. To increase the efficiency, then, the holes must be smaller and spaced farther apart; that is, less of the plate cut away in a line across the plate in drilling rivet holes. This is accomplished by increasing the pitch in any row (pitch is abbreviated to P), spacing the rivets farther apart, always measured from center to center, and putting in as many rows as may be needed to get the desired shearing strength. There are limitations to pitch on account of calking the joint steam-tight.

Another term met with is "crushing strength" (called C for short) which means that the part of the plate directly in front of the rivet may crush, the same as a bar of flat iron, if set up edgewise and subjected to extreme pressure, would crush. This must not be confused with the tearing out of the rivets through the edge of the plate. The crushing strength (C) of boiler plate, as indicated by numerous tests, is about 95,000 per sq.in. section, so that value is generally accepted as the value to use in all calculations; but since C is such a high value, it does not demand serious attention, for the joint is more likely to fail otherwise before the limit of C is reached. The thickness of the plate is shortened to t and the thickness of the butt straps to t_1 or these may be varied by different writers, but a list of abbreviations is, or should always be, given so there need be no confusion in a given case.

As suggested before, the net section of the sheet between the rivets is the part that is left to resist the strain (this is called the ligament), and the same applies to the slant distance between adjacent rows; so the rows must not be too close together, for the plate may fail in a zigzag line from a rivet in one row to an adjacent one in the next row and back, even though the pitch of a given row be sufficient. This is not likely to happen if consideration is given to the manufacturing process, for space must be allowed for the "dolly" used in riveting.

I think you and your friends will have a lot of fun designing joints (on paper) and testing them out by critical analysis and incidentally become familiar with the "nicknames" used.

A Talk to Firemen on Saving Coal*

BY CHARLES H. BROMLEY†

A simple, straight-from-the-shoulder talk to firemen, giving in one lecture the most important things to do to get the most out of coal with the hope that firemen and their employers will become interested enough to further study fuel economy as the problem confronts them.

FIRING is an art that cannot be learned from books. Experience alone is teacher. But one becomes a much better fireman in a given time by studying and by hearing what those who have studied the subject have to say. That is why your good friends in Baltimore have arranged this meeting for you.

Of course it is impossible in one lecture to tell you all I want to tell you; but I will touch the most important points, hoping you and your employers will become interested enough to take up the subject and each study his individual needs.

EMPLOYERS NEED EDUCATION

So much is at present said about how firemen waste coal and how necessary it is to educate them, that I am impelled to say that the employers of firemen need more education on the use of fuel than do the firemen themselves. The most skilled and technically competent fireman cannot burn coal economically unless the boiler and furnace are, first, suitably designed for the coal used and, second, properly maintained in repair and cleanliness. In the average plant the fireman has nothing to do with design and little to do with repair and upkeep. The engineer or superintendent is properly responsible for these. The fireman is shown the boilers, given the most ragged-edged scoop (the older fellows on the job have grabbed the best ones) and put to work. Firing is hard and dirty work, and the class of men in boiler rooms becomes less congenial every year. These are the conditions.

The employer should learn that he must furnish the most suitably designed furnace and apparatus if he expects good results from his boiler room day in and day out.

The days of hand-firing are numbered. The great variety of mechanical stokers put on the market in the last few years adapts the stoker to almost any coal and any size or number of boilers. There is every physical and labor reason why the commercially unavoidable waste of coal by hand-firing should cease. Firemen, therefore, should visit stoker-fired plants and study the construction and operation of the many types of stokers. Ask your employers to send for the various stoker catalogs and give them to you. But do not use them to set the coffee pot on.

The more the fireman knows about the fuel he burns, and how and why it burns, the better he can burn it. The fireman's job is to put into the water in the boiler all he can of the heat in the coal. To successfully burn most soft coal, the combustion chamber must be of large volume and, for some types of boilers, have arches and wing walls to thoroughly mix the gases rising from the coal. The hand-fired horizontal return-tubular boiler and most hand-fired water-tube boilers should be set so that the heating surface nearest the fire is 60 to 72 in. above or away from the fire. The distance for stoker-fired boilers should never be less than 60 in. If the settings leak, find the cracks by passing a lighted candle over and near the brickwork or by passing the hand over the setting. Fill the cracks with a mixture of old asbestos from discarded pipe covering and fireclay or cement, or with some one of the several preparations on the market.

It is to be assumed that the baffling is tight so that the gases do not go to the stack without passing over the heating surface.

The following refers to soft coal: Coal is composed of carbon, tarry substances in solid form and refuse. The more tarry substances the coal contains the more smoky it is. When heated, the tarry substances vaporize, like ice melts, then vaporizes, if thrown on the stove. The vapors from many coals begin to be driven off at temperatures as low as 400 deg. F. The usual furnace temperature of a hand-fired boiler is 1800 deg. or higher. This explains why soft coal smokes when thrown on a hot fire—the vapors are driven off so rapidly and are so dense and the furnace temperature so reduced by blanketing the fire that smoke or vapor instead of gas forms.

HINTS ON THE CARE OF FIRES

The following instructions apply particularly to soft coal, hand-fired, but are true in general for hard coal.

Starting the Fire: Cover the grate with about three inches of lumpy coal. On top of this throw wood enough to start the fire; ignite the wood with oily waste. The coal will catch fire from the top down and will not smoke disagreeably. For hard coal and coal having less than 20 per cent. volatile, like the New River, Pocahontas, Clearfield and others, the fire will start better by throwing the coal on top of the wood. Do not try to make a thick fire at the start; keep it thin and hot by putting on the forced draft, if provided, except in a Scotch boiler or a newly set boiler. The reason is that the brickwork is cold and good combustion cannot be had until the brickwork, especially the arches, if there are any, is very hot. With most boiler furnaces, letting air in at the fire-doors after firing will prevent the formation of black smoke. If steam jets to blow air in over the fire are provided, use them for a minute or so after coaling the fire.

Holding the Fire: Do not carry the fire more than 12 in. thick. Cover it by coaling the fuel bed first on the front half; when this has burned through, cover the back half. If this method is not desirable, coke the coal by piling it at the dead plate. When coked as much as the condition of the fire gives time for, push the coking coal onto the fire. Cover the fire only where it burns away; that is, in the "holes."

---

*From a lecture to the firemen of Baltimore, Md., at the Baltimore City Club, Jan. 9, under the auspices of the Baltimore Engineers' Club, the Baltimore Section of the American Society of Mechanical Engineers and the City Club.

†Associate editor, "Power."

Use the slice bar seldom and be careful not to turn over the fire so that ashes or clinkers get on top of the live coals. If they get there, they will melt, run through the fuel bed and harden at the grate, plugging the air spaces. A very thick fire may have the same effect, except that the grate bars may become overheated and warp enough to ruin them. Run the slice bar between the grate and the fuel bed and raise the clinker enough to break it and let air through to the coal above.

With ordinary coal, if the ash and clinker give frequent trouble by melting, the cause is likely too high furnace temperature. This may be reduced by cooling the furnace arch over the fire, removing it altogether, exposing the bottom row of tubes if covered with tile baffling by putting the tile on the row above, or by bricking off part of the grate if the highest load can be carried with less grate area. The ash-fusing temperatures of Pocahontas, New River, Clearfield and Georges Creek coal are between 2400 deg. F. for the first to 2900 to 3000 deg. F. for the last. Most of the Pittsburgh and Kentucky coals have ash that melts at as high and few at lower temperatures than these.

CLEANING THE FIRES

The following directions are applicable to a stationary grate. Have plenty of live coal before beginning to clean. Push the live coal on the front half of the grate onto the back half; pull out the ashes, cover the bare grate with a thin layer of green coal and pull all live coal at the back of the grate forward onto the front half. "Jump" the ash from the rear over the fire and out the door. Cover the grate as before.

Some prefer cleaning one side half and then the other. The method is the same except that the live coal is pushed or "winged" over to one side, the grate cleaned of ash, covered with green coal and the live coal pushed back. The same is done with the other side of the fuel bed.

With shaking grates the ash is shaken into the ashpit; but if large, heavy and hard clinkers form, they should be pulled out of the fire. Shake frequently enough to keep the fire about eight inches thick and push the slice bar over the grate and under the clinker, lifting it enough to crack it. If the coal crusts over on top, break the crust with the rake frequently.

A FEW HINTS ON THE STOKERS

With most stokers cleaning is done automatically; but if large clinkers form, they must be broken so the air can get through to burn the coal fed to the fire. The coal now being delivered in most localities contains half again to three times as much ash as that supplied before the war, and more serious clinker trouble results. No rigid directions can be given for getting clinker off the side walls without too quickly destroying the wall. Experience with the particular coal and brick in the wall must govern the operator. Be careful to break the clinker so as to burn the carbon out of it before the clinker gets on the dump plate, otherwise it will continue to burn there and in some stokers will burn out the plate. Break the clinker that piles up near the dump-plate so the air can get through it to burn out the carbon.

If the stoker has a clinker grinder and air may be admitted to the clinker on the grinder, be careful not to let in so much air as to overbalance what may be gained by burning the carbon out of the clinker. Experience gained by checking up with analyses of the gases and experience with the particular coal must govern the burning of carbon from the clinker. This is true whether the clinker grinder is run continuously or the clinker accumulated, ground and the carbon burned out periodically.

The more coal you attempt to burn the more carbon there will be in the ash, other conditions unchanged.

It will be found that for nearly every particular coal and type of setting there is a certain combustion rate above which it is uneconomical to go. For peak-load periods this rate is usually exceeded. The engineer must find this rate and instruct you accordingly.

Do not regulate the draft solely by the ashpit doors; use the back damper, which should be operated from the boiler front where the draft gage should be located.

SOME GENERAL HINTS

Keep the coal swept back away from the boiler front.

If you find you cannot help coal dropping off the shovel and going into the ashpit, tell the engineer so and let him put screens of ¼-in. mesh at the ashpit-door openings.

Pull the ash from the ashpit immediately after cleaning the fire, especially if the ashpit is shallow. This avoids warping the grate bars and prevents the formation of clinker. Keep water in the ashpit if it is very shallow.

Do not let the clinker form at the side walls so badly as to interfere with the feeding of the coal or enough to "arch" over the fire.

Never crawl under a fire to replace a grate bar that has jumped its bearing. It is too dangerous for you and too costly for the employer if you are badly injured.

Keep the business end of your scoop trimmed evenly. It won't spread coal rightly if it has a raveled edge.

If steam jets are used to create pressure draft under the grate, keep the jet openings free of the lime or other solids that come over with the steam and plug the tips.

If the fine anthracite is dry, wet it before firing, provided it cannot freeze before you want to shovel it. If it blows away at the dead-plate, clear the place and put lumps of coal or clinker over the slit from which the coal blows away.

Feeding water to the boiler is, perhaps, more important than feeding coal to the furnace. The feed water should be as hot as exhaust steam and live steam can make it, and there should be a thermometer in the feed line. Aim to feed water when the load is light and have a shade more than two gages full when the heavy load comes on, so that you can shut the feed valve almost entirely during the heavy load. When down to a little above the first gage-cock, open the feed valve just enough to keep the water going into the boiler as fast as it goes out in the form of steam. But make sure the injector or spare feed pump is ready for business in case the feed pump breaks down. If the water is such that it foams badly at heavy loads, keep it low and feed it continuously; that is, don't try to fill up the boiler and then shut off the feed when the heavy load comes on. Practice will tell how high a water level you may have before you get foaming trouble. Clean the fires during the lightest load periods only.

If the engineer neglects to keep in working order the dampers, damper regulator, the balanced draft apparatus, the feed valves, the feed-water regulator or anything important to the boilers' operation, pester him until he does act. If he is still negligent, every man jack in the boiler room report the conditions to the chief.

If stoker-fired, keep the stoker-coal hoppers full all the time and see that lumpy coal does not segregate at one side or both and fine coal in the middle of the hopper; otherwise you cannot keep a fire free of holes. The more uniform the size of the coal fed to the stokers the better fire you can maintain.

Never allow the wooden ladder to be taken from the boiler room, even by the chief himself.

It is foolish to try and cheat the CO_2 recorder or the gas-sampling tank. You can do it, of course, but you are the one who suffers. Play square with these watchmen, who, after all, are your best friends.

If the other fellow makes a better firing record than you do, don't get sore—learn from him. But if he cheats by shutting off the blowers on his boilers and makes yours do most of the work—well, use your own judgment.

I cannot say too strongly that opportunities for bright, studious boiler-room men are great now and will be greater as time goes on. There is always a good job, at good pay, for the man who knows the boiler room and how to get the most out of it.

M. I. T. a Military Camp

The remarkable registration of the Massachusetts Institute of Technology, which has today 88 per cent. of the students who were there in June at the close of the last school year, is due to two important factors: First, there was the plain statement by a student committee to its fellows that their patriotic duty was to "sit tight" and finish their studies, when they would be of much greater benefit to the country; and second, there were the summer military camps.

Two camps were established—one for sophomores (200 registered) at East Machias, Me., and one for juniors in Cambridge, Mass. The Institute has, on Gardner Pond, Me., a summer engineering camp ground of about 600 acres. Attendance there is obligatory upon sophomores in the civil-engineering courses. It was decided to utilize the facilities for a larger sophomore camp whose studies would be engineering as well as military.

Twelve weeks in uniform with military regime was the course, and to assure it to students to whom the uniform, transportation and camp costs would be a burden yet who were patriotic in wishing to undertake it, the expenses up to $25,000 were underwritten by Mrs. Edward Cunningham, widow of a former member of the Institute Corporation, through a memorial fund to her husband.

The work at East Machias included all kinds of engineering. Situated on the lower one of three large ponds, with considerable flowing streams at hand, hydraulics was an important topic. Railroad engineering was also taken up under natural conditions surrounding such work, and trenches were laid out and excavated. The summer was passed in this way, and the students were all the while engaged in the study of military science and evolutions and manual with considerable artillery practice. These students almost to a man returned to the M. I. T. for their junior year.

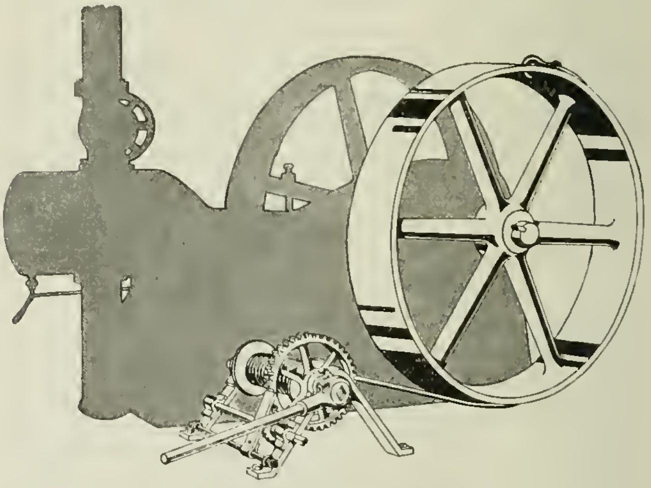
At the same time the junior camp was established at the Institute in Cambridge. This was a camp of nearly 200 students in khaki uniform, officered and taking calisthenics and military work. Students who wished to attend this camp but whose circumstances would ordinarily have caused them to seek positions during vacation had the benefits of the Cunningham memorial fund. There students with a long day, lasting till 5:30 p.m., not only had military training, but were anticipating the studies of the senior year so that they will actually receive their degrees a month hence and be able to go at once into that technical service which the country so much needs.

Institute men to the number of 1200 are already in khaki in positions of responsibility in all branches of military and naval service, while a larger body, more than 2000, are in the equally necessary supporting industries allied to war.

Engine-Turning Winch

Many devices have been used in power plants for turning engines off the dead-center. These are generally bars of one kind or another by which the engine is pried over, the bar gripping, or engaging in holes or notches in, the flywheel rim.

A different method of doing this work was recently seen in operation in a steam plant. The engine was a center-crank with flywheel governor. In the rim of the flywheel were holes for changing the governor for reverse running. On the floor in front of the flywheel was a winch, over the drum of which a wire rope was wound, the loose end having a hook. This hook is placed in one of the holes in the flywheel rim. On the extension of the winch shaft a ratchet is attached to which is fitted a handle.



WINCH FOR TURNING ENGINE

With the hook in the hole of the flywheel the ratchet is operated, thus winding up the wire rope and turning the engine to the desired position. The winding spool is prevented from turning backward by a dog engaging with the gear teeth.

Gas-Engine Troubles and Remedies

By A. L. BRENNAN, JR.

Although during the past few years internal-combustion engines have reached a high degree of perfection, they are still subject to many of their former troubles. How these troubles may be quickly and intelligently diagnosed is told in the following.

THE troubles in gas engines can in the most part be avoided by careful attention, but at the same time they are liable to take place, even if an engine is in charge of an expert. It must not be understood from this that gas engines are not entirely dependable, for the service they are giving in all motive-power applications should be sufficient to convince even the most skeptical of their reliability.

Considering the fact that the functions of gas engines are partly performed by combustion, partly mechanical and partly electrical, it is not surprising that they cause trouble at times. When a gas engine refuses to start, it may be due to any one or more of three general causes—mechanical, fuel or electrical.

Mechanical troubles are:

1. Lack of compression.
    a. Inlet valves stuck (automatic).
    b. Inlet valves out of time (mechanical).
    c. Broken, scored or worn piston rings.
    d. Dry or worn cylinder.
    e. Leaky gaskets or compression valves, etc.
    f. Faulty exhaust valves.
2. Excessive friction.
    a. Poor quality or insufficient lubrication.
    b. Load not disengaged, or clutch sticking.

Fuel troubles are:

a. Insufficient volume of gas allowed to cylinders.
b. Improper gas mixture.
c. Water in cylinders.
d. Water in carburetor.
e. Needle valve of carburetor clogged up.
f. Pipe line clogged up.
g. Gasoline supply exhausted or tank air-locked.
h. Throttle not opened wide enough.

Electrical troubles are:

a. Open circuit due to switch not in contact.
b. Open circuit due to loose or broken wire.
c. Short-circuit due to broken-down insulation on wires.
d. Igniters hung up (mechanical make-and-break).
e. Weak or depleted batteries.
f. Poor contacts at timer.
g. Vibrator contact points dirty or out of adjustment.
h. Dirty or defective spark plugs.

Although there are many minor troubles that might be listed here, they would in general only tend to confuse the operator. The leading troubles, as outlined in the foregoing, should prove of benefit to the average engineer in helping him to quickly decide upon and locate an existing fault.

As a first step toward locating trouble in a gas engine the mechanical features of the motor should be tested by trying the compression. That is, crank the motor over with all relief valves and cocks closed; if considerable resistance is encountered on the compression stroke without any indication of binding, it is evident that the compression is good and that the valves and other actuating parts that control the compression are in good order. It must be remembered that each cylinder should undergo this test and if the compression is not satisfactory, the cause should be ascertained and remedied. No internal-combustion motor can develop its maximum power without good compression, although it may be able to operate in a fairly satisfactory way.

Also, if the compression is good, the features affecting the combustible are in all probability in good order as well. These have to do with the factors that control efficient carburization. Carburetors are an auxiliary feature of a gas engine for converting the liquid fuel into a gas, but at the same time carburization is largely dependent upon the condition of the motor. Therefore, any troubles that interfere with good compression, such as a badly pitted exhaust valve, for instance, also operate against efficient carburization, and, as already stated, this point is brought out by testing the compression. Therefore the first thing for an operator to do when confronted with difficulty to start is to try the compression; if this is good, the trouble is in the carburetor or the ignition.

When Motor Fails To Pick Up

Assume that the ignition is known to be in good order, and an attempt to start the motor is made but it fails to pick up, and each cylinder is primed and the motor again cranked over. If, now, the engine starts and runs in a regular manner, it shows that there was nothing much at fault to begin with and that the motor failed to start owing to lack of fuel in the cylinders when first cranked over. But on the other hand, suppose that after priming and cranking the engine it fired the priming charges and stopped, accompanied by sharp backfiring in the intake manifold or carburetor on four-cycle motors, or in the base or carburetor on two-cycle motors. Backfiring of this nature indicates a weak mixture, but does not necessarily show that the needle or air-valve adjustments are at fault, for the trouble may be due to the needle valve in the carburetor being clogged up or the flow of gasoline in the pipe line may be impaired by sediment or the tank may be airbound, etc. If, after priming and cranking the engine, no explosions took place, this would indicate that the motor is flooded. Therefore the next thing to do is to get rid of the extra gas, by closing the throttle, opening the relief cocks and cranking the engine over several times. It is a good plan to keep the switch on during this cranking, for then when the gas is thinned down sufficiently, firing will take place and the motor will start. Just as soon as the motor picks up its cycle, open the throttle a little and close the relief valves or cock and then advance the spark.

Remember that failure to start is not due to a retarded spark, and under no circumstances should the spark be advanced before the engine is operating under its own power. Failure on the part of the operator to fully retard the spark before cranking has resulted in many serious accidents. When a motor is started either with or without being primed and runs in a powerful manner for two or three cycles, but slows down or stops sluggishly, it is in nearly every case a positive indication of an over-rich mixture, consequently steps should be taken to reduce the amount of gasoline allowed or increase the volume of air.

On the other hand, suppose it appears that the ignition is at fault. The best way to see if the entire system is all right is to test the spark plugs, if the motor is equipped with high-tension coils. To test the plugs they should be removed from the cylinders, the high-tension wires reconnected and the threaded portion of the plugs rested upon the cylinder, care being taken to keep the top of plug and terminal from contact or near the cylinder. Then place the switch in position and crank the engine over to the several firing points—that is, to the firing point of each cylinder—and note if a spark takes place between the points of the plugs. If a good spark appears at each plug, evidently the ignition is good, but this should not be taken as final for the reason that a weak battery or poorly adjusted coil can produce a spark under natural conditions, but the same potential will prove inadequate to induce an electric arc in the high pressure inside the cylinder. Therefore this fact should be kept in mind, and unless an exposed plug shows a good, fat spark, steps should be taken to make up this discrepancy by adjusting the coil or using new batteries.

Another point to remember in connection with spark plugs is that the porcelain part is liable to crack and cause them to fail in their function, owing to the current leaking through the cracked porcelain and grounding.

If, when the motor was turned over to the firing point, no spark appeared at any one or more plugs, but the vibrators worked all right, this would show that the existing trouble is either in the secondary windings of the coil, in the high-tension wires or in the spark plugs. It is very rare that an operator is troubled by a defective coil, therefore the trouble is probably due to a loose high-tension wire or to a defective spark plug, and so the best thing to do is to change the spark plug of the faulty cylinder to one that is known to be in good working order.

On the other hand, if the motor was turned over to the firing point of each cylinder and each vibrator failed to buzz, it would indicate a weak or depleted battery, loose or broken wire in the primary circuit, poor contacts at timer or vibrator contact points dirty, pitted or out of adjustment.

Some Shaft-Governor Pointers

One evening as Willis was passing the plant of the Davis Machine Co., where a young fellow named Arnold was in charge of a couple of shaft-governed cross-compound engines, he noticed that Arnold was putting in some overtime, and as the latter usually made it a point to get away from the plant about as soon as the office boy, Willis stepped in to see if he could be of any help.

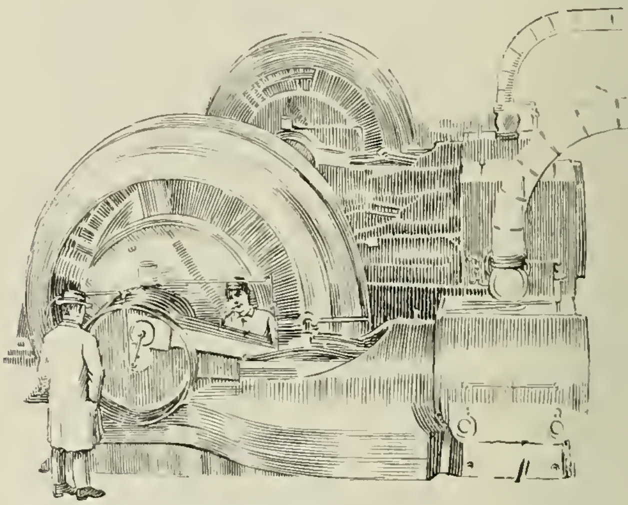
"What's the trouble?" he asked, as Arnold stuck his head up by the governor wheel. "I thought you would be at the movies by this time."

"Movies nothing," growled Arnold. "I have all the movies that I want right here with the blasted governor of this engine."

"What seems to be the trouble? Perhaps I can help a little."

"Racing, that's all. You'd think that the blamed engine was going to its first circus if the speed were anything to go by."

"Well, let's see if we can't get down to brass tacks before you take that governor down. What receiver pressure have you been getting since this trouble began?"



IT'S KIND OF FUNNY YOUR ENGINE SHOULD START TO RACE ALL OF A SUDDEN

"Oh, around 45 to 50 lb. Of course that is high, but what can a fellow do? The plant has to run, racing or no racing."

"Sure, sure. But it's kind of funny that your engine should start to race all of a sudden, when it was running all right only a couple of weeks ago. Do anything to her since then?"

"Nothing to speak of," answered Arnold. "I did a little valve setting about a week and a half ago, but that hasn't had anything to do with the racing. How could it?"

"Now let us reason together, as someone has said. You carry about 115 lb. of steam at the throttle and get between 45 and 50 lb. receiver pressure. It looks to me as if there was something the matter with the valve setting. I'll bet your fireman will swear that you are eating up steam faster than you used to."

"He has kicked a little, but I told him it was his imagination. I don't see how it could be anything else."

"If I were you, Arnold, I would look at the valves just the same. Suppose we take off the bonnets and see what we shall see. I have an idea that you are blowing live steam right into the receiver from the high-pressure cylinder."

"I don't believe it, but just to show you that you are wrong we will look into things and see."

"There you are," exclaimed Willis when the valves were exposed to view. "Just what I thought. You have given the steam valve about $\frac{3}{16}$-in. negative lead, and your piston will be at about $\frac{5}{8}$ of its stroke when the valve opens and keeps open until near the end of the stroke. At the same time the exhaust valve on that end of the cylinder is open and the steam doesn't do a thing but rush right out through the exhaust port to the receiver. Can't you see that you are working the low-pressure cylinder at a pretty high pressure? It's no wonder that the engine races. Let's set these valves as they should be and see what happens when you start up.

"Another thing for you to consider is that with this valve setting an excessive back pressure is set up in the high-pressure cylinder and of course that reduces the power developed by that cylinder. With the low-pressure cylinder doing the most of the work, it is out of the control of the governor and there is no reason why the engine wouldn't race. Now with these valves set properly, according to my notions, I'll bet a plugged ten-cent piece that your engine will govern all right."

When Arnold started up for a tryout, he found that the tendency to race had disappeared.

"Well, I'll be blown!" he exclaimed. "I wouldn't have believed I had set those valves so as to knock out that governor. I'll be more careful the next time."

"That is a good resolution to make, but every engineer should be so familiar with his engine that he knows just what he is doing when changes are made. And that applies to the governor. Many times poor regulation is due to a faulty governor—not so much in the design as to the wear of parts, which will frequently cause them to bind. A governor should be known to be in balance as to weights and friction."

"I don't get you," said Arnold as he seated himself on the edge of his desk. "How are you going to find out whether the weights and friction balance, whatever that is?"

"That's easy enough. All you have to do is to detach the springs from the weight arms and move the weights out to their full travel and back again with a free movement. If the governor binds, it is well in testing out to remove the eccentric rod so as to give the governor free action without having to drag the valve gear. Working the weight arm from one position to another will give a good idea as to whether there is binding in the parts or not. If there is a feeling of sticking, you won't have to guess very much as to where the trouble is."

"Suppose you do feel a sticking when working the weight arms, what are you going to do about it, and where would you look for the cause?"

"The first thing I would do would be to examine the pins and bearings to see if they were getting enough oil, or for caps binding on the end of the pins. If you feel a sticking of the movement, you can be pretty sure that the trouble is in some of the governor bearings or pins. Naturally, if after testing out the governor it is found to be all right, you will turn your attention to the valve gear. It may be that a pressure plate is binding, or the valve stem may bind in the stuffing-box. Flat pins can bring about a lot of trouble."

"I don't see why that should be," said Arnold as he started to remove his overalls and jumper preparatory to getting ready to go home.

"That's easy to explain. When an engine runs day after day with practically the same load, the bushings and pins will wear out of true, because the governor arms assume practically the same position during the run. Naturally, the pins and arm bearings wearing together have a free motion, but if the load changes to any great extent so that the weight arms take a new position, the bearing between the arms and the pins do not fit properly and excessive friction is set up, often so great that the governor sticks, the result being that the engine will race."

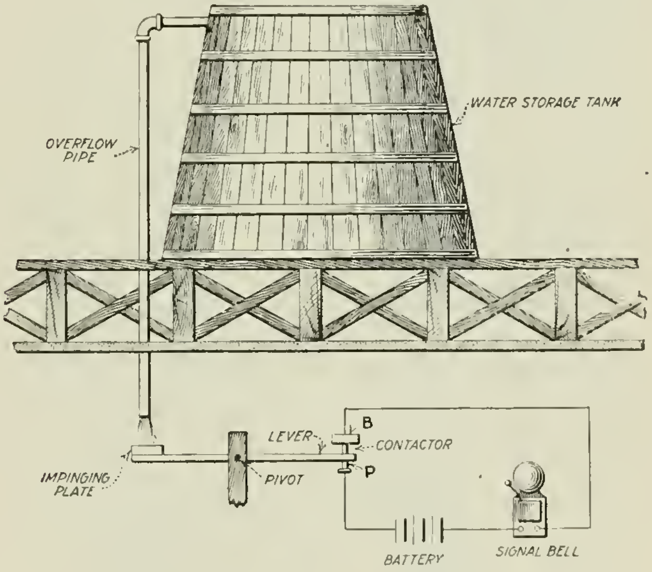
"I guess there is considerable in what you have said," answered Arnold. "One thing is sure and that is that poor valve setting will cause an engine to race, but for the 'love of Mike' don't go away from here and tell the bunch what a mess I made of setting those valves."

"I won't," replied Willis, as he buttoned up his overcoat. "I've been guilty of pulling off just such fool stunts myself"; and with this he left Arnold to wash up, while he hurried home to another belated supper.

Tank-Overflow Alarm

By T. A. Nash

An effective tank-overflow alarm circuit is detailed in the figure. When the tank becomes so full that water flows through the discharge pipe, the water impinges on a block mounted on the end of a lever as shown. This forces the contact point *P* of the lever against the metal contact *B* and completes the signal circuit, causing the bell to ring.



LAYOUT OF TANK AND ALARM CIRCUIT

Experience has shown that undercutting the mica is desirable on most commutators having peripheral speeds exceeding 1500 ft. per min. In the case of very low speeds, slight undercutting, possibly one sixty-fourth inch, may be desirable. Nonabrasive brushes should always be used with undercut mica, because where there is little wear on either brush or commutator, there will be practically no grinding off of either copper or carbon, hence no fine material to fill the grooves. In general, undercutting is entirely satisfactory for any machine operating at engine-type or higher speeds.

The Electrical Study Course—Forms of Field Magnets

Some of the earlier and the modern types of field-frame structures used for direct-current machines are described.

THE function of the field magnets in an electric generator or motor is to furnish the magnetic field, which in a generator is cut by the armature conductors to generate voltage, and in a motor reacts upon the current flowing in the armature conductors to produce rotation. In the development of the dynamo-electric machine the field magnets have taken on a multiplicity of forms. The field magnets of the earlier types of dynamos were permanent horseshoe magnets, similar to that shown in Fig. 1. Even today this type of field pole is used, in some cases, on small magnetos for ignition, signaling and other purposes. However, this form of magnet was never used on machines of any considerable size, chiefly because the magnets would have to be very large; the strength of the magnets decreases when in use, owing to the vibration of the machine and the effects of the magnetic field set up by the current in the armature winding; also because there is no way of controlling the strength of the field, which is the chief means usually employed for controlling the voltage of the generator or the speed of an adjustable-speed motor. These defects soon led to the adoption of electromagnets; that is, coils of wire placed on polepiece of soft iron and excited from some source of electric current.

Early Types of Field Magnets

Since the permanent-magnet field poles were of the horseshoe shape, it is to be expected that most all of the earlier electromagnets used for field poles were of this form. Fig. 2 shows one of the early types of Edison two-pole machine, and Fig. 3 is a somewhat later and improved type of the same machine. In this arrangement of poles, if they were mounted on an iron base it would short-circuit the magnetic field; that is, instead of the lines of force passing from the N pole across the air gap, and through the armature core into the S pole, they would take the easier path around through the iron base. To overcome this defect, a nonmagnetic plate of brass or zinc was placed between the polepieces and the baseplate, as indicated. To prevent the lines of force from leaking out along the armature shaft down through the bearing pedestals into the base of the machine and back into the polepieces, the pedestals were usually made of brass.

To get away from the nonmagnetic bearing pedestal and bedplate, the polepieces were turned upside down with the armature placed in the top, as in Fig. 4. With this arrangement the field magnetism passes from the N pole into the armature through the armature core into the S pole, and down around through the baseplate. Another form of field magnet is that in Fig. 5. This type was usually mounted on a wooden base, for the same reason that the nonmagnetic plate was used in Figs. 2 and 3

In all the foregoing schemes the flux from the polepieces passes directly from one field pole into the armature, and then to the opposite pole and around through the field structure. Such an arrangement is called a salient-pole machine.

Consequent-Pole Type Machine

Another type of field pole used in the development of the electric machine is given in Fig. 6. In this construction if the top of one field coil is made north and the other south, the lines of force will flow from the N pole around to the S pole without ever passing through the armature at all. To overcome this difficulty the top ends of both coils are made the same polarity; therefore the bottom ends must also be the same polarity, as shown in the figure. In this arrangement the two N poles oppose each other, and the lines of force must take the next easiest path, which is down through the armature to the S pole. A machine having a field frame in which like poles oppose each other, so as to cause the flux to pass through the armature, is called a consequent-pole machine. One of the serious objections to this type is that the opposing poles cause a heavy magnetic leak around through the air from the N to the S pole; that is, instead of all of the flux passing from the N pole into the armature and then to the S pole, a large number of the lines fly out in all directions into the air and around to the S pole. This leak constitutes a direct loss. In all types of machines there is always a certain amount of magnetic leakage, but it is much more pronounced in the consequent-pole machine than in the salient-pole type.

Motors or generators with only two poles are called bipole machines; those having more than two poles, that is, four, six, eight, etc., are called multipolar machines. None of the types of field frames so far considered lend themselves readily to multipole construction, consequently very few of these types were developed into multipole designs.

Materials Used in Field Poles

The arrangements of poles in the field frame that have been exploited could be carried out almost indefinitely, but the one design that is now used almost exclusively is the arrangement shown in Fig. 7. This construction is of the salient-pole type; that is, there are no opposing poles. This design can be used as readily for bipole as for multipole construction.

All of the earlier field frames and polepieces were constructed of cast iron or steel. In some of the modern types the whole field structure is laminated; that is, built up of thin sheets of iron or steel. Others again have a cast-iron yoke to which laminated polepieces are bolted. The yoke is the circular portion in Fig. 7. Other types have cast-iron polepieces with laminated poleshoes. The poleshoe is indicated in Fig. 7. This part is built up of thin sheets of iron or steel and bolted to the cast-iron polepiece. This subject will be given a more detailed study in future lessons.

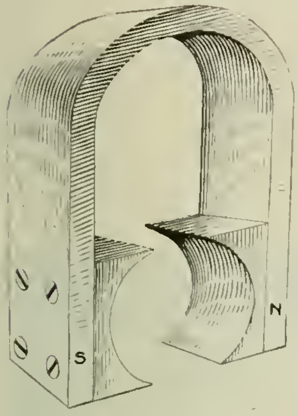


FIG. 1

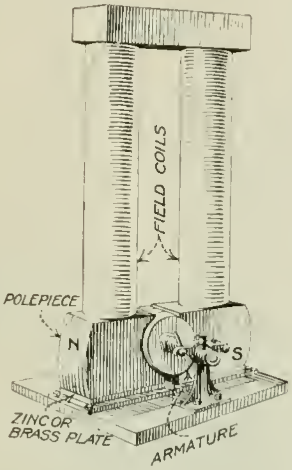

FIG. 2

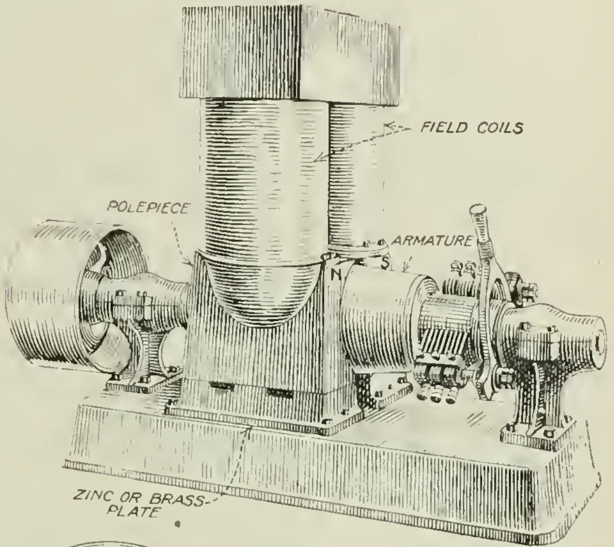

FIG. 3

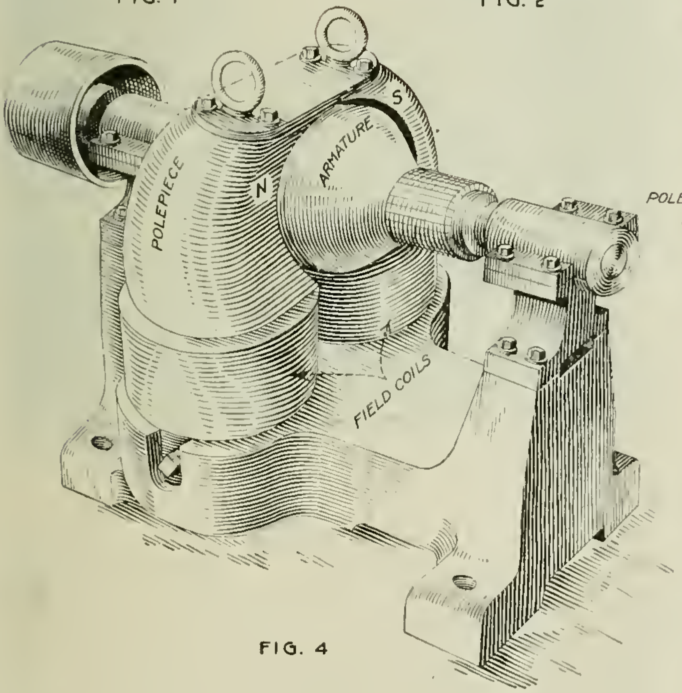

FIG. 4

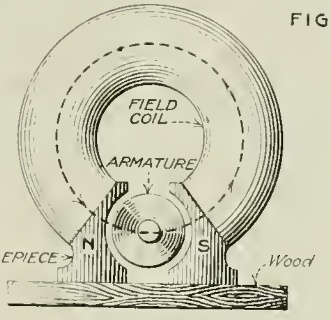

FIG. 5

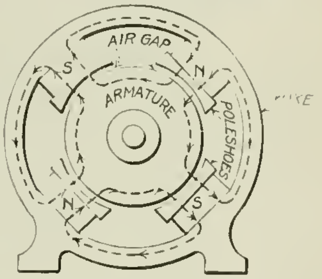

FIG. 7

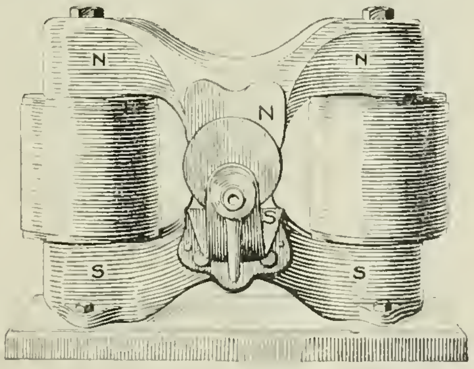

FIG. 6

FIGS. 1 TO 7. DIFFERENT TYPES OF FIELD-POLES FOR DIRECT-CURRENT MACHINES

Fig. 8 shows the layout of the study problem given in the last lesson. The current required by the motors is equal to total horsepower × current per horsepower $= 37.5 \times 3.8 = 142.5$ amperes; the current consumption of the lamps equals the watts required per lamp × the number of lamps ÷ volts $= 75 \times 64 \div 235 = 20.4$ amperes; and the total current is the sum of that required by the motors and lamps, or $142.5 + 20.4 = 162.9$ amperes. The volts drop in the line is $E_d = E - E_a = 240 - 235 = 5$. Then the size of the conductor required is

$$Cir.mils. = \frac{21.4DI}{E_d} = \frac{21.4 \times 475 \times 162.9}{5} = 331{,}176$$

or the nearest larger size standard conductor is 350,000 cir.mils., which is the size that will have to be used. This size rubber-covered conductor can be used, since the National Board of Fire Underwriters allow it to be loaded up to 300 amperes. Total watts = volts × total current, or $W = E_a I = 235 \times 162.9 = 38{,}281.5$; total kilowatts $= \frac{W}{1000} = \frac{38{,}281.5}{1000} = 38.2815$. The total time during which the power was used is hours per day × number of days. In this problem $6.5 \times 26 = 169$ hours. Then kilowatt-hours = kilowatts × hours $= 28.2815 \times 169 = 6470$. The cost of the first 800 kw.-hr. at 7.5c. per kilowatt-hour is $800 \times 7.5 = \$60$. The next 1000 kw.-hr., at 6c. per kilowatt-hour, cost $1000 \times 6 = \$60$. The remaining kilowatt-hours $= 6470 - 1800 = 4670$, and the cost, at 4.5c. per kilowatt-hour, is $4670 \times 4.5 = \$210.15$, and the total cost is $60 + 60 + 210.15 = \$330.15$.

1. What will be the voltage drop per foot of copper wire 18,750 cir.mils. in cross-section, when transmitting a current of 35 amperes?

2. Three lamps having a resistance of 45, 90 and 180 ohms respectively, are connected in parallel at the end of a 75-ft. circuit, the conductors of which have a cross-section of 6530 cir.mils. If 135 volts are applied to the power-plant end of the circuit, what current will flow through the lamps? Also the current taken by each lamp?

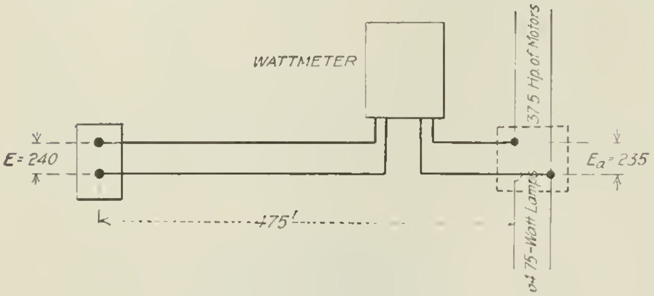

FIG. 8. FEEDER AND BRANCH CIRCUITS

Power Without Cost?

The Paterson (N. J.) *Morning Call* of a recent date contains the description a "near perpetual motion" discovered by a local inventor who, it is said, has been granted a patent on the device, which is expected to develop unlimited power by the upward rush of air through a conical stack or tower containing a vertical shaft on which are several propeller-shaped blades. "The apparatus may permit mills to discard coal." "Model develops 325 r.p.m." (doing no work except—overcoming its own friction presumably). The inventor "is too modest to permit the use of his name." "He does not wish his apparatus to be confused with so-called perpetual-motion machines." The reporter, however, suggests that "if the machine is as successful as he claims it will be, there is no reason why it should not be perpetual, as the air currents are continually mounting skyward." "It is not expected that one of these towers will furnish enough power for ordinary manufacturing purposes, but a whole battery of towers can be put in use at the same time," and "it will not be necessary to use any kind of manufactured drafts or currents."

APPARATUS FOR DEVELOPING POWER

Engineers will recognize the fallacy of the reasoning in the foregoing, in that there can be no upward flow of air except when the air inside a chimney is at a higher temperature, therefore lighter. A chimney is the simplest form of heat engine and at the same time probably the most inefficient. It costs something to "stir up a breeze" in any case, and even if it costs nothing to produce, it might easily cost more than it is worth to get any useful work out of it.

"Ideal" Commutator Resurfacer

A commutator resurfacer made of abrasive nonmetallic material has been perfected recently by the Ideal Commutator Dresser Co., 8 South Dearborn St., Chicago. The resurfacers are made in various sizes to fit any condition of service. They are secured to permanent handles, giving the operator easy control of the device while on the commutator. The resurfacer is designed to do what would be accomplished by putting the commutator in a lathe and turning it down. There are two grades, known as coarse and fine. The former is recommended for bad commutators; the latter for a commutator in fair condition. Both cut down high mica, high bars and smooth out low spots, ridges and grooves. It is claimed that the abrasive material of the resurfacer does not collect copper dust nor wear smooth. Consequently there should be no short-circuiting, so that the device may be applied to a commutator or to collector rings while the machine is in operation. The illustration shows one of several designs of resurfacer with handle, made by the company.

Work of the New Orleans Fuel Administration Committee

By LEO S. WEIL

This article describes the work being done by the New Orleans Committee of the United States Fuel Administration to conserve the supply of coal in that city under the direction of the writer, who is acting as Advisory Engineer to the committee. Considerable saving of coal has already been effected.

THE Fuel Administrator has appointed state administrators with advisory committees, whose duties are (1) to stimulate production, (2) to regulate prices, (3) to control the distribution, and (4) to conserve the supply of coal. While these duties are all important, those which deserve the greatest attention at the present time are stimulating the production and conserving the supply. If these two aims can be carried out successfully, there will be sufficient coal to satisfy the needs of all. The New Orleans Committee of the United States Fuel Administration has inaugurated an energetic campaign for fuel conservation, and an outline of the work being done will probably be of interest to other communities.

After a careful study of the situation, the committee decided that coal could be saved in three ways: (1) By the substitution of other fuel where available, (2) by shutting down unnecessary plants and lightening the loads on plants that must run and (3) by improving operating conditions. Steps were first taken to find a substitute for coal, and to this end a letter was sent to all woodworking plants in New Orleans and vicinity asking for a report on the amount of wood waste they had in excess of their own requirements, with the idea of using this excess instead of coal wherever it was commercially practical. To obtain this information "General Letter No. 4" was sent out.

UNNECESSARY PLANTS SHUT DOWN

Investigation showed that the ice plants of the city operate in the winter months at about one-third of their normal capacity, and an arrangement was therefore made whereby a large number of these plants were shut down and the remainder run at nearly normal capacity supplying ice to those which were shut down. Coöperation to the same end has been received from other industries such as the laundries and the New Orleans Railway and Light Co., which have dispensed with all unnecessary loads. The greatest possibility of saving exists, however, in improving plant-operating conditions, and to this the committee is devoting much of its effort. The Government has appealed to mine workers to speed up the production of coal in order to take care of the increased demand, and it was thought that a similar plea could well be made to power-plant owners, their engineers and firemen not to waste coal, because any amount of coal saved would be of even more benefit than a corresponding increase in production, as it would release freight cars for other service. A meeting of the industrial-plant managers was therefore called, at which the necessity of fuel conservation and the individual duties of owners, engineers and firemen were impressed on those present. It was pointed out to the managers of the plants that one of the principal reasons that they did not receive the most efficient coöperation from their operating forces was because suggestions from the latter were not given proper consideration when these suggestions called for improvements entailing a small expenditure. They were advised to encourage suggestions from their engineers even if they did not always adopt them, because nothing stimulates the interest of a man in his job so much as the realization that his opinion is valued and that any improvement in results that he obtains will not pass unnoticed. The plant owners were given to understand that they would not be expected to make large investments to improve operating conditions, but that they would be expected to keep their present equipment in good condition and to utilize this equipment to the best advantage. "General Letter No. 6" was distributed, pointing out where most of the easily preventable wastes occur in steam plants, and it was requested that the various suggestions on this sheet be checked up to see that these wastes were cut to a minimum.

COMMITTEE OF OWNERS FORMED

The necessity of coöperation on the part of both owners and engineers was strongly urged, and it was decided to form a committee of owners and also an organization of engineers to assist in this work. In pursuance of this policy "Circular Letter No. 8" was sent to all industrial plants in the city, and it is gratifying to state that pledges of coöperation and support were received from all these plants. A committee of five industrial-plant owners has been appointed to confer with the advisory engineer and to help direct this work. "Questionnaire No. 9-A" has been mailed to the engineer of every plant in the city. The information called for on this questionnaire will indicate whether the results being obtained are as good as they should be and will help to show why they are not good if the efficiency is low. A committee of operating engineers will also be appointed to assist the advisory engineer in analyzing these reports, and suggestions will be made to each plant on the best method of improving its operating conditions. This same staff of engineers will also visit the various plants to study conditions and; after consulting with the engineer of that plant, will report to the owner on possible savings that can be effected. A similar questionnaire will be sent out each month, and the replies received will show what saving is being made. Posters that have been prepared by the United States Fuel Administration (General Letter No. 6) will be placed in every boiler room and an appeal made to the firemen to show their patriotism by following directions on these posters.

Both engineers and plant managers have shown every inclination to help the work along, and a considerable saving has already been effected, which will be increased as time goes on, and it is hoped that the results obtained will fully justify the effort made.

GENERAL LETTER NO. 4

To the Woodworking Plants of New Orleans.

Gentlemen: As an aid in the work of fuel conservation, the New Orleans Committee of the United States Fuel Administration request that you give them the following information:

1. What kind of power do you use to operate your plant?
2. Do you make any use of the wood waste obtained in manufacturing your product?
3. Does this waste exceed your own requirements, and what disposition do you make of the excess?
4. State the amount of this excess and advise whether you are willing to dispose of it to other steam plants in your vicinity.
5. Give the names of the plants in your neighborhood that might be able to use this wood waste as a substitute for other fuel.

If further information is needed by you in order to answer these questions, you will please communicate with the advisory engineer of the board, Leo S. Weil, 303 Whitney-Central Building.

Your prompt coöperation will be of great assistance to the committee, and is earnestly requested.

Yours very truly,
HAROLD W. NEWMAN, Chairman.

GENERAL LETTER NO. 6

To the Users of Industrial Coal in New Orleans.

Subject: How To Reduce Coal Waste.

1. Keep the heating surfaces of the boilers free from soot, scale and oil.
2. See that the baffling is in good condition and that the gases follow the proper path.
3. Be sure that the boiler settings are tight and free from air leaks.
4. Work your boilers up to their rated capacity. Do not have more boilers in operation than are necessary to carry the load.
5. Do not have too much grate surface for the size of the boiler.
6. Do not have openings in grates so large as to lose a large amount of combustible with the ash.
7. Fire light and often, spreading the coal over the thin spots in the fire.
8. Keep the fires level and free from holes.
9. Use the dampers to regulate the draft; not the ashpit doors.
10. Do not carry the fires so thin or have so much draft as to draw a lot of excess air through.
11. Do not carry the fires so thick or cut down the draft so much as to have incomplete combustion of the coal.
12. Admit some air over the fire to complete combustion.
13. Do not soak the coal with water before firing.
14. Be sure the blowoff valves do not leak.
15. Do not have the safety valve popping off continually.
16. Use your exhaust steam to heat the feed water; do not waste it.
17. Have the valves on your engines properly set.
18. Minimize radiation losses by covering steam pipes.
19. Do not allow the waste of steam through leaky traps, valves, etc.
20. Never use live steam where exhaust is available and can be used as well.
21. Do not have belts too tight or so loose that they slip; keep all shafting in line.

CIRCULAR LETTER NO. 8

To the Managers of the Industrial Plants of New Orleans.

In accordance with the suggestions presented at the meeting last Thursday night, it has been decided to form an organization of owners of industrial plants in this city to coöperate in the efforts for the conservation of fuel. All coal users in New Orleans will be expected to join this organization, and a committee will be appointed from the members to coöperate with the New Orleans committee of the United States Fuel Administration.

The members of the organization will pledge themselves to use every effort to save coal; to follow suggestions approved by the local committee to this end; to provide the necessary instruments for ascertaining their operating conditions; and to keep records of these conditions, which will be submitted periodically to the Fuel Administration.

The local committee is confident that the patriotism of all steam users here will prompt them to join in this work. You are requested to signify your intention of coöperating by filing your membership pledge with the committee not later than Dec. 21.

The engineers of the local industrial plants will also be organized for the same purpose, and you are requested to bring this matter to the attention of your engineer and ask him to pledge himself to the work, at the same time.

A meeting of the operating engineers will be called to discuss ways and means of conserving coal, as soon as the replies are received.

We urge upon you the necessity of this fuel conservation work, and feel that we may count upon your coöperation.

Yours very truly,
HAROLD W. NEWMAN, Chairman,
New Orleans Committee Federal Fuel Administration
for Louisiana.

December ...., 1917.

Kindly enroll the undersigned in the conservation campaign of the United States Fuel Administration as above indicated.

....
....

Name of engineer employed:
....

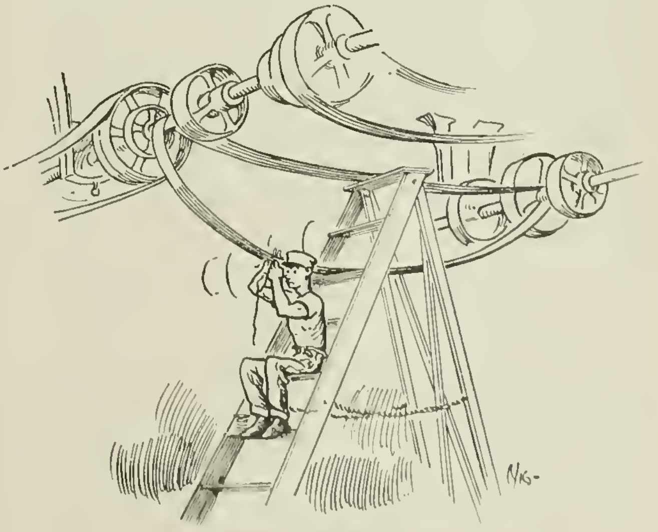
After signing the above, and furnishing the information requested, kindly return to the New Orleans Committee, Federal Fuel Administration, 402 Canal Bank Annex.

QUESTIONNAIRE OF THE POWER PLANT, NO. 9-A

(Date)..................

Name of plant........ Manager........ Engineer........
No. of boilers in plant........ make........ size........ grate surface.......................
Plant runs....hr. per day....days per mo.....mos. per year
Daily output of plant in per cent. of maximum............
No. of boilers operated.........method of firing.........
Kind of fuel used........ Amount per day........ Heating value........B.t.u.
*Water evaporated per day.........per lb. of fuel.........
*Temperature of feed water..........
*Average stack temperature...........
*Average per cent. CO_2...........
*Draft in furnace..........in uptake........(usual).
Usual thickness of fires.............
Do the firemen keep fires level and free from holes?.......
Are the boiler walls cracked or leaky?...........
Is the baffling in good condition?............
Is the heating surface clean from soot and scale?..........
How often are the tubes blown?............. System of blowing................
Do the blowoff valves on the boiler leak?.............
Are the valves on your engine properly set?.............
When indicated last.................
Is steam pipe covered?............
Live steam used for...........................
Exhaust steam used for..............
Can you suggest any way of reducing the fuel consumption of your plant, and how much do you estimate can be saved?......................

*If you lack instruments to measure these, say so.



THERE ARE OTHERS

Faulty Lubricating Methods

By Charles W. Oakley

The brasses of the eccentric rods on a large engine are of the marine type. An oil hole drilled through the end of the brass and an oil cup mounted on a pipe connection, as shown in Fig. 1, were to provide the means of lubrication. As a matter of fact, however, lubrication should be by way of the oil hole *A* in the top of the brasses, the cup being of little value because the oil fed from it flows to the bottom of the brasses and away from the pin, which has its principal bearing at the top. If the pin made an entire revolution instead of a slight rotating movement, the oil from the cup would do some good, but in any event the cup should have been mounted on top of the brasses with an oil hole leading down through the rod end and brasses to the pin.

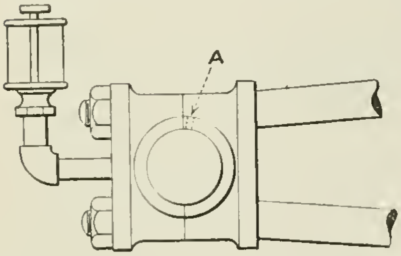


FIG. 1. OIL CUP SHOULD BE AT A

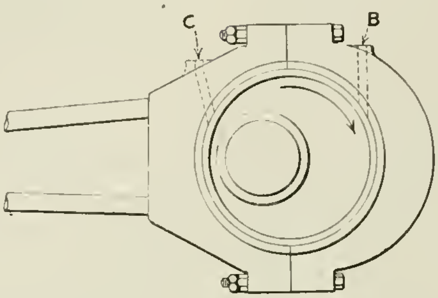

FIG. 2. STRAP SHOULD BE OILED AT C

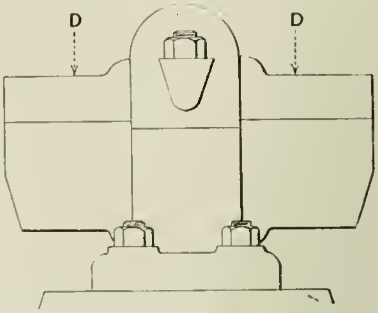

FIG. 3. SUGGESTED RINGS SHOULD BE AT D

Another case of poor design in applying lubrication is found on the eccentric strap of the same engine, where the oil is introduced through the strap at *B*, Fig. 2. As the direction of rotation is toward *B*, as shown by the arrow, most of the oil is carried down and lost at the slack side or bottom of the eccentric strap. If the oil cup were mounted at *C*, the oil would be carried immediately to the top of the eccentric where the weight of the strap and rod are supported, and the lubrication would be accomplished with less oil.

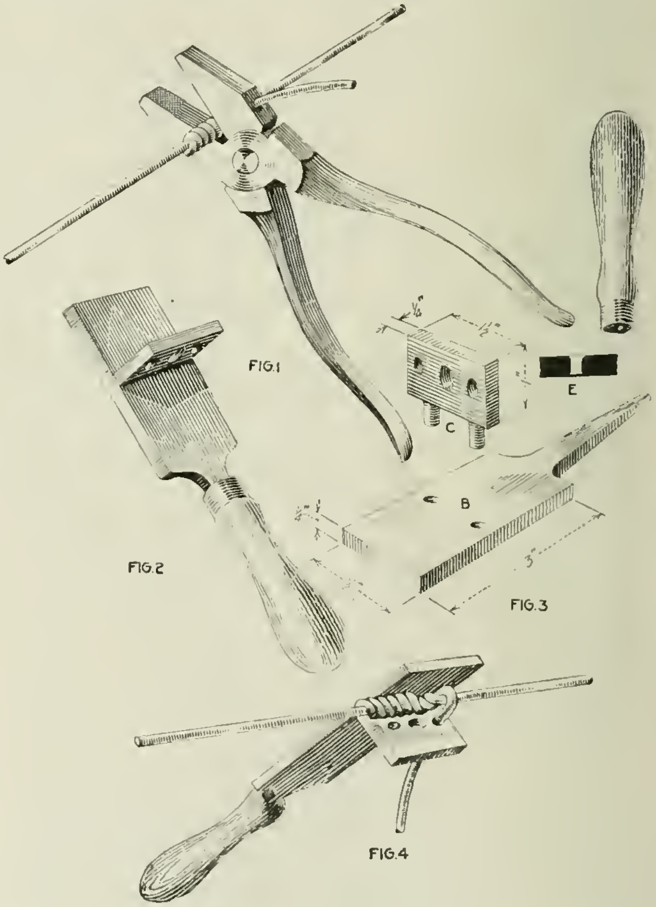
In the same plant a pair of jackshaft bearings carry a $6\frac{1}{4}$-in. shaft, the journal being about 26 in. long and constructed about as shown in Fig. 3. They are of the ring-oiling type with a single ring in the middle of the bearing, covered and hidden from view by the cap and yoke. This single split ring is not only insufficient to carry oil enough to properly lubricate the bearing, but in case of the ring stopping or coming apart, which has happened, there is no way of detecting it until the bearing is overheated. A pair of oil rings placed at *D*, *D*, with an opening over each for observation, would give better results and insure against a possible shutdown from a hot bearing.

Tools for Splicing Wire

By M. P. Bertrande

Everyone knows what a difficult job it is to splice solid hard-drawn copper or iron wire without suitable tools. In order to obtain a perfect joint, tension must be exerted on the wire ends while winding the splice, and this cannot very easily be done with the common type of cutting pliers. The self-explanatory illustration, Fig. 1, gives a clear idea of what may be done to overcome the difficulty. A $\frac{3}{16}$-in. hole is drilled in the soft part of one jaw of the pliers. Then by inserting the end of the wire to be wound and rotating the plier, a perfect tight joint is obtained.

Fig. 2 shows a wire-splicing tool that makes an excellent joint. It winds the joint tight up to the very end of the wire, something impossible with any kind of pliers. While the joint is being made, the other end of the wire is held by a pair of pliers. The tool consists of a piece of machine steel *B*, Fig. 3, to which a right-angle extension *C* is riveted. Three holes for the different sizes of wire are drilled, for holding the ends of the wire to be wound on the splice, as shown in Fig. 4. The holes for the wire should be well rounded, as shown at *E*, Fig. 3, so as to give the wire a good sliding surface.



FIGS. 1 TO 4. SPLICING TOOLS, PARTS AND ASSEMBLY

Editorials

The Pooling of Power

AT THE meeting of the American Institute of Electrical Engineers held in New York on January eleventh, there was read and discussed a very timely paper, "The Effect of War Conditions on the Cost and Quality of Electric Service," by L. S. Goodman and W. B. Jackson. Toward the close of the discussion, W. N. Smith called attention to the fact that in the large manufacturing districts in and about New York and other large cities there are, among the larger factories, many steam-power electric-generating plants which could be made available as auxiliaries to the central stations in times of emergency by commandeering them into a pooling system under the jurisdiction of Federal or state authority, which could be exercised through public-utility commissions or boards of engineers appointed for the purpose. While such auxiliary stations could not generate with as little fuel per kilowatt as the large central station, their load factors would probably be benefited. These distributed facilities and fuel supplies already existing would, in times of shortage, become immediately available for the needs of the community without having to wait longer than it would take to switch the auxiliary equipment to the existing systems of distribution.

The application to public use, on an extended scale, of such stand-by auxiliaries, would, of course, have to be carefully worked out by competent engineers, but it is perfectly feasible of accomplishment, both as to apparatus and circuit connections.

With a system of private plants pooled under control of public authority, it would become possible to enforce greater fuel economy than now exists in many of the factory plants available for commandeering, since they would be supervised by engineers who would be in a position to enforce the most economical methods of operation under the circumstances. It is an unfortunate fact that the average factory plant, in which the expense for fuel and power is small in comparison with the total manufacturing cost, is not run as economically as a similar plant owned by a public-service corporation or a manufacturer whose principal expense is for steam power. The manager of a plant of the former type pays little attention to the manner in which his steam is generated or used, provided he gets it when and where he wants it. In such cases boiler efficiency is as likely to be forty per cent. as seventy per cent. But with the system proposed, there could be brought to bear upon commandeered private plants some authoritative pressure from without, which is about the only method left to persuade an inefficient factory superintendent that it is better for him to improve his boiler and engine efficiency than to have his fuel supply for factory purposes reduced or cut off as a penalty for wasting it. Another advantage to the commandeered factory plant would be the increased certainty of its fuel supply upon becoming an auxiliary public utility.

In localities where war activities have put extra pressure upon all sorts of industry requiring fuel, it is time to apply to the central-station interests the same principles of coöperative pooling as are now being applied to the steam railroads by the highest public authority, to the great advantage of the public interest. It does not require much imagination to perceive both the ready-to-hand possibilities of helping out the central stations and of aiding in fuel conservation at factory plants used as auxiliaries, which would result from the institution of a system such as that outlined, of pooling central stations and private plants in the public interest.

The nonarrival of a single bargeload of coal, prevented by an ice blockade from reaching a central station, would not then be a matter of such moment to the community as it is now, when without warning, any part of the load on a large central station or important substation may be "pulled" by the load dispatcher and some sections of the community deprived of transportation or of the means of factory operation, or plunged into darkness.

We take occasion to remind the engineering profession and the general public of some of the methods of electric-power generation and distribution that were commonly practiced in the largest cities twenty-five or thirty years ago, in the early days of the electric-lighting industry, before the advent of the modern central station. At that period responsible central-station companies operated not only central stations of a few thousand horsepower capacity, but also had tied in with them or operating on separate circuits little isolated stations with a few small belted units in each, stuck around town in basements or in rented space adjacent to convenient boiler rooms; or else bought the output of small units operated by owners of factory plants at wholesale rates and resold the distributed output for both public and private lighting and power. To be sure, rates were higher then than now and fuel and wages were cheaper; but the point is that the public actually received pretty fair electric service from these heterogeneous, disjointed outfits operated in private isolated plants that were auxiliaries to the small central stations of that day. An emergency service from an auxiliary system of commandeered factory plants would certainly be better than no service at all from a large central station.

If this whole matter were taken up under public authority in any industrial district by the utilities commission having jurisdiction or by a board of engineers appointed for the purpose, it would be a simple matter to prepare an inventory of available isolated plants, with all necessary data as to their present duty, hours of service, usual fuel supply and storage capacity, cost of operation and the equipment and connections necessary to harness them to the existing distribution systems. With this information at hand and with the organization for utilizing it in the public interest, the central stations could be effectively supplemented and reinforced in their important functions. The public would then have additional protection against the sudden crippling of a big steam-turbine unit or against a blockade on the fuel supply of some important central station, both of which causes have recently operated to curtail electric service in the New York district.

If the attitude of the central stations is one of helplessness in a difficult situation, for which they are not responsible, they should be willing to be helped by public authority in the interest of the public whose creatures they are and whom it is their main business to serve. No one, least of all a private manufacturing concern, wants to subtract anything from the legitimate business of a central station or any other public utility; but if the public interest in the present vital emergency requires more perfect continuity of service than the central stations can give it unaided, it would seem that a concrete, practical remedy is not nearly so remote as the pessimistic statement of the problem would lead us to believe.

By utilizing the auxiliary steam-plant resources now available, the public will be better served, the strain on man-power and on financial credit will be to a large extent relieved, the available fuel will be more intelligently used than it is at present, the private power-plant owner will be stimulated into realizing his public obligations and will be incidentally rewarded by greater certainty of his fuel supply; and while the central-station interests will not be permitted to assume that their electric-supply facilities are the only ones available in a grave public emergency, they will, on the other hand, not be expected to perform the impossible.

While it is perfectly reasonable under ordinary circumstances to consider that a central-station electric-supply system is best administered as a monopoly, the status of the central station, being primarily just as dependent on the fuel supply as the isolated plant, takes away its apparent independence, after all, and makes it really a competitor of the isolated plants, so that in its economic relation to the community it becomes subject to the principle that, as in the case of the railroads, the public interest is better served by coöperation than by competition.

The War and the Individual

IT IS highly probable that the Third Liberty Loan will be launched about March first; but this much is certain—it will not only exceed in amount the two that have preceded it, but it will be the largest single war loan ever offered by any nation.

The prompt and complete absorption of so vast a sum —and no right-thinking person has any misgivings as to the successful accomplishment of that end—will require the whole-hearted support of every loyal citizen. It will mean sacrifices greater than those that have been made; it will involve self-denial to an extent which neither necessity nor inclination have yet been able to enforce; and it will demand of the individual the giving up of purely personal pleasures and conveniences to contribute to the benefit and well-being of all. But the true American stands ready to undergo all these discomforts when he realizes that by so doing he is strengthening our fighting arm and thus bringing the end of the war nearer.

There has been an unfortunate tendency on the part of some individuals to view the war as a thing remote and detached. They agree that conservation policies are needed to prevent waste, but they have done little themselves to carry out such policies. They continue to indulge in luxuries and extravagances to which they were accustomed in peaceful times, and by that very act they divert to the production of nonessentials a part of the labor and materials which should be devoted to the one great, overwhelming purpose of the present—the winning of the war.

It is charitable to explain away such action on the ground of thoughtlessness; but to admit that excuse is to emphasize the necessity of wider publicity concerning the relation of the individual to the present conflict. We must get away from the bald statement that the nation is at war and realize that we ourselves are in the war; for, after all, the nation is but the aggregate of individuals. The responsibilities and the hardships must rest upon us in equal measure, just as we expect to share in equal measure the fruits of victory.

The scarcity of foodstuffs and the shortage of fuel have done much to impress upon the individual how close the war comes to his own doorstep. He is at last awaking to the fact that his habits of living must be readjusted to meet the greatly altered conditions, and to prevent the rapid recurrence of such stringencies as have already been experienced. The lesson has been taught severely, but the truth is wholesome.

From this time forward there will be a closer watch kept on individual expenditures, greater economy in the consumption of necessities, and a growing willingness to do for oneself the things that were formerly left to others, all of which will result in making available additional wealth and energy for carrying on the war. The Third Liberty Loan will be oversubscribed, exactly as the two that have preceded; but it will be done by the dollars of those who put necessities before nonessentials, service in place of self-gratification, and patriotic devotion above all else.

Yet it is not enough that the loan be fully subscribed; it should be absorbed quickly. The rapidity and spontaneity with which our people answer the appeal of the Government for funds will be an unmistakable indication of their interest in the war and their willingness to assume its burdens. The effect produced on the minds of German militarists by the swift raising of the whole amount of the loan is an advantage not to be regarded lightly.

The cost of running the thousands of lights which are burned unnecessarily may be insignificant, but the cost to the average householder of running a few extra bulbs overtime makes a very significant difference in the monthly account rendered. We are glad to see that Fuel Administrator Garfield has made a positive move toward restricting this waste, and hope his order will be complied with without disparaging criticism.

We have often wondered why some philanthropists and conservationists have not endowed a fund to put a few convincing talkers on the road to show power-plant owners how much their engineers may save with the aid of a water meter, coal scale, Orsat and a few thermometers. Gifford Pinchot, Andrew Carnegie and the Rockefeller Foundation please take notice.

Correspondence

Change in Water Supply for Air Pump of Leblanc Condenser

In *Power* of Nov. 20 Mr. Forseille brings up some interesting points on the subject of the change in water supply for air pump of Leblanc condenser. The two problems as stated in his query are: First, that of furnishing a Leblanc condenser with enough water to get a good vacuum; second, that of getting rid of slush ice on strainers in the water-supply line to the air pump.

The first is by far the most serious as it causes a loss during the whole year. In Table I is given a comparison of the conditions as stated by Mr. Forseille with those that would obtain with larger amounts of condensing water. Water rates of 32 (Mr. Forseille's stated rate), 45 and 60 lb. per pound of condensed steam are shown as representative of the range of possible improvement. For intermediate points curves can be drawn or reference can be had to tables of vapor tension, and this tabulation can be augmented to cover any comparisons required. In this table it is assumed that the exhaust steam discharged to the condenser contains 950 B.t.u. per pound. Under each of the three water rates are tabulated the conditions for cooling-water temperatures of 32, 60 and 100 deg. F., which nearly cover the range Mr. Forseille says he has to operate on.

TABLE I. A COMPARISON OF REPRESENTATIVE CONDENSER CONDITIONS

Lb. Water per Lb. Steam	32			45			60		
Cooling-water temperature, deg. F.	32	60	100	32	60	100	32	60	00
Rise in temperature, deg. F....	30	30	30	21	21	21	16	16	16
Discharge temperature, deg. F.	62	90	130	53	81	121	48	76	116
Vapor tension at above discharge temperature, lb.	0 56	1 41	4 52	0 40	1 06	3 52	0 33	0 90	3 05
Corresponding vacuum with 30 in. barometer...	29 44	28 59	25 48	29 60	28 94	26 48	29 67	29 10	26 95

Actual vacuum is likely to be from 0 3 to 0 4 in. mercury lower than these values.

A rearrangement of the above vapor tensions and vacuums to make the comparisons more clear is shown in Table II.

TABLE II SUMMARY OF VAPOR TENSIONS AND VACUUMS ARRIVED AT IN TABLE I

	Cooling Water Temperatures, Deg. F		
Water per Lb.; Steam, Lb	32	60	100
32	0 56	1 41	4 52
	29 44	28 59	25 48
45	0 40	1 06	3 52
	29 60	28 94	26 48
60	0 33	0 90	3 05
	29 67	29 10	26 95

Referring to the tables, it is seen that increasing the condensing water from 32 lb. to 60 lb. will improve the vacuum about ¼ in. when cooling water is at 32 deg., about ½ in. at 60 deg., and 1½ in. when water is at 100 deg. The result of improvement in vacuum in terms of cash value is brought out forcibly in Mr. Baker's article in the Dec. 4 issue of *Power*.

If the pump turbine in this case is now working to the absolute limit of its capacity, little can be done but to replace it with a turbine or motor big enough for the job; but if it is capable of being speeded up by overhauling or readjustments, there can be no doubt that it would pay.

I notice that Mr. Forseille says that the air-pump supply valve is kept at a constant setting under all conditions. This suggests to me that it may be taking more water than necessary and, if so, is giving the turbine extra work to do from which there is no return.

The vapor tension values used above are from a table given by the Westinghouse Machine Co. in its instruction book WM 102.

The second problem is that of preventing ice formation on the strainers in the supply lines to the air pump. One point involved here is that of vapor tension of the hurling water. As this water is depended on to condense any condensable vapors that may reach the pump, and as it passes through a region of vacuum after it passes through the blades of the impeller, the vacuum produced is controlled by the temperature of this water and its corresponding vapor tension. See the tables.

Another factor of importance is the air discharged, entrained with the water, through the main discharge pipe. There is always some air passing out of the condenser in this way, the amount probably varying with the depth of submergence of the pumps; but if the pumps are run fast enough to lower the water level to the suction opening of the pumps, additional air will be trapped and carried out with the water. To use this water in the air pump would add to the free air in the condenser. It would also be likely to interfere with proper working of the air pump by breaking up the "water pistons" as they leave the impeller blades.

If Mr. Forseille had given more details as to elevations and the vacuum gage readings on suction or injection lines, more might be said about how operating conditions could be improved.

For preventing ice forming on the screens I suggest tapping in a jet of steam or hot water just below where the air-pump line leaves the main line or a jet just ahead of each screen.

The above discussion was written before reading Mr. Johnson's contribution in the Dec. 18 issue, and from the start it was assumed that it was impossible to follow the scheme Mr. Forseille suggests. C. W. BELL.

Hauto, Penn.

Worn Latch Blocks Cause Racing

When I took charge of this plant, which is equipped with Laidlaw-Dunn-Gordon-Hamilton gear pumping engines, I had a great deal of trouble with the latch blocks wearing and the engines racing, caused by the head end letting go too early and the crank end going in full gear or not unhooking at all. I did not know what the matter was; neither did the builders nor those who did the erecting. The crank end would go in full gear about every third or fourth revolution, so you can imagine what a time I was having. I had been a marine engineer and had had no experience with Corliss engines, but it occurred to me that possibly the blocks were unlatching too soon; so I put my thumbs on the springs to help the tension of the springs, and to my surprise the engine stopped racing. I then got wise and turned the blocks around so that new edges or sides came together. That was all right so far, but all the service I could get out of the new edges was about 15 days, after which they would begin to cause racing again.

One day when *Power* came, I sat down to read it, and under the head of "Correspondence" I came across a letter by an engineer who had been having the same kind of trouble that I was having. He said that he had had blocks made out of No. 00 steel and it cured the trouble. I made up my mind that if it was a good thing in his case, it would be good in mine; so I had similar blocks made and put a set on one engine Aug. 3, 1911, and on another Sept. 30, 1911. I have not had a bolt out of one of them since.

If there is anything in this that you think worth publishing, do so, but do not send me anything for it, for I do not want it and will surely send it back if you do, as it is written in gratitude for the "pointer" received from *Power* several years ago. I hope this may do someone some good. R. A. DAVIDSON.

Colton, Calif.

Operating Two-Phase Motors Single-Phase

A number of years ago, when the plant in which I am employed was built, two-phase alternating-current equipment was selected, consisting of one 50-kw. and one 75-kw. generator, with exciters, supplying twenty 5-hp. induction motors of the squirrel-cage type, some fifty inclosed arc lamps for general illumination and about two hundred and fifty 16-cp. carbon lamps for local lighting. The motors were 220 volts as well as the carbon lamps. The arc lamps were of the multiple type, and groups of four were served by compensators or balance coils, furnishing 110 volts. Shortly after the plant was put in service, business became dull, and as a result many of the machines were shut down; consequently a number of the motors were running considerably under full load, causing the power factor of the plant to be low.

A test was made, and the load conditions of the plant at that time were about as follows: Apparent kilowatts as shown by the ammeters and voltmeters, 47.4; true kilowatts as shown by direct-reading wattmeters, 19.6; power factor at switchboard, equal true kilowatts ÷ apparent kilowatts = 19.6 ÷ 47.4 = 0.41.

As the 50-kw. generator, which was supplying the load at that time, was heating considerably, it was decided if possible to improve the power factor. After considering several plans, I fell upon the idea of operating the two-phase motors single-phase, starting on two-phase and then cutting one phase out when the machines were up to running speed. This would give the single-phase in use nearly full load and perhaps correct the power factor. I also discovered that by removing two contact blocks I and II, shown in the figure, from the drum of the auto-starter, one phase could be cut out when in the running position. Since with this type of compensator the drum always turns in one direction, the section with the two contacts removed would be in phase *A* at one time when starting and the next time in phase *B*. The motors were started and stopped twice per day, consequently if phase *A* was in service in the morning, phase *B* would be in use in the afternoon, so that both sets of windings of the stator would be in use during alternate halves of the day. However, if for any reason any of the motors were stopped during the day, the handle of the starter would have to be thrown over twice to maintain the load balance in the phases. Two ammeters on the main distribution-panel box circuit indicated the load in each phase, therefore making it possible to see that the system was kept as nearly balanced as possible.

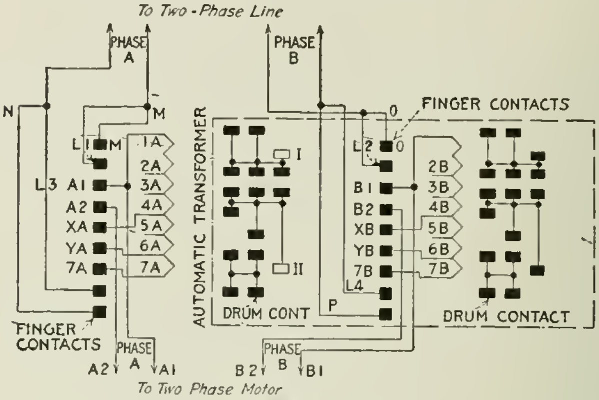


DIAGRAM OF COMPENSATOR CONNECTIONS

One motor was at first arranged to run single-phase as planned, and operated for a week with no trouble. The manufacturers of electrical equipment were then consulted as to what would result from the change. They replied that under the circumstances there would be a slight improvement and that no harm could come to the apparatus operating under such conditions. Eight motors were run on that plan during slack seasons, which occurred during every summer and recently both summer and winter; but I had never known, owing to the lack of proper instruments, how much improvement the change had produced until in October, 1916, when, owing to the high price of coal and the difficulty in obtaining it, the manager was persuaded by a central-station company to permit a test to be made by their expert. The result of the test was as follows: Apparent load, 37.125 kw.; true load, 19.4 kw.; power factor = true load ÷ apparent load = 19.4 ÷ 37.125 = 0.52. It will be seen that although the true load in both tests was nearly the same, the apparent load was much less with part of the motors running single-phase.

During recent years the tungsten incandescent lamps have been substituted for the arc lamps, and in order to permit the use of the 110-volt current necessary, the old balance coils of the arc lamp were employed with satisfactory results, 3000 watts or less being carried by each without difficulty and with very little heating. These coils are arranged on the roof trusses, one in the center of each group of lamps. When the incandescent lamps are burning, they have practically 100 per cent. power factor, and the power factor on the whole circuit is 76.8 per cent., the power factor of the motor load being as stated. With every machine in the factory running and all motors operating two-phase, the motor-load power factor was 66 per cent. With this motor load and the lights all on, the power factor was 77.4 per cent. These are the central-station company's own figures.

Weehawken, N. J. F. W. **Plumb.**

[Operating polyphase motors single-phase is a practice that in general is advised against, but under the conditions it would seem to have some advantages. *Power* invites the opinion and experience of interested readers on the foregoing subject for publication.—Editor.]

Modification of the Pitot Tube

It would appear that the modified Pitot tube depicted on page 876 in the issue of Dec. 25, 1917, is not fully described or else is entirely erroneous. The static pressure within the pipe would cause a full-caliber flow through the valve even if there was little or no flow in the main, therefore the slight velocity head added in any case would make little difference.

It is possible that the intention is to calibrate or measure the flow through a restricted orifice under a given pressure at no flow, then measure the flow under the combined influence of the static and velocity head and calculate the velocity from the increased delivery. At any rate the contrivance does not seem to be logical as presented. J. **Lewis.**

New York City.

Electric Lights for Small Plants

When on an automobile trip recently, I stopped at the pumping station of a Massachusetts town. I was cordially greeted by the engineer who, among other things, took pride in his lighting set inasmuch as it was original and, as he thought, cheap to operate. Fig. 1 shows the set, which consists of a small Pelton waterwheel direct-connected to two small direct-current generators. The wheel's water supply, at 180-lb. pressure, is through a 2-in. pipe connected with the pressure pipe of pumping engine, and the discharge from the wheel is connected to the pump suction. The engineer claimed that the cost of current was considerably less than two cents per kilowatt-hour.

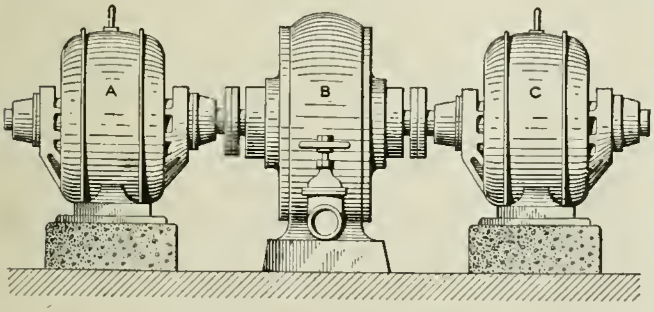

FIG. 1. TWO GENERATORS DRIVEN BY A WATERWHEEL

In another plant visited, the generator was driven as shown in Fig. 2. Two heavy iron columns *D* were erected near the flywheel of the pumping engine, and two long screws *E* were secured to them on which two bearings *C* could be raised or lowered at will to bring the leather-covered pulley *B* in contact with the flywheel.

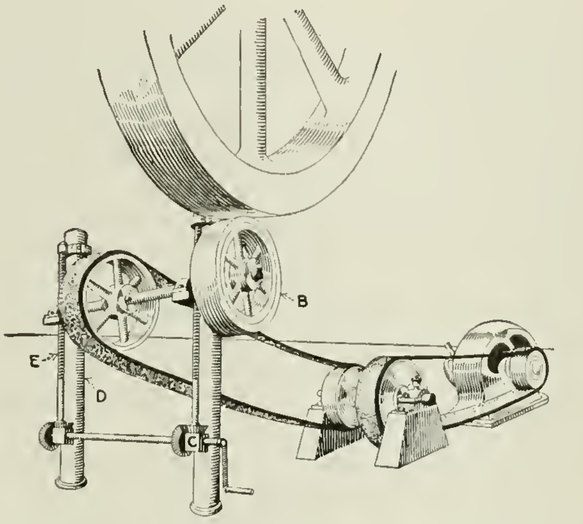

FIG. 2. DYNAMO DRIVEN FROM A FRICTION PULLEY

By this means the station was electrically lighted, otherwise oil lamps would have to be used.

Methuen, Mass. P. E. **Merriam.**

Care of Hydraulic Elevators

Hydraulic elevators require more attention than electric, and where there are a great many cars in service they should be placed under the management of a competent elevator man.

On high-pressure systems the pilot valves will most frequently require attention, as they become clogged with dirt and particles of packing carried through the pipes, and must be blown out. Next comes the packing of operating valves with leather cups, which either blow out if end cups or blow through if inside, either of which will cause the car to creep or settle. Motor valves, operating the pilots, should also be inspected and the flax packing rings renewed if necessary.

Each morning the water that has accumulated in the lunger pans should be removed and the plungers oiled (while running) with lard oil, as this is best where there is water. When the glands are within a half-inch of all the way in, the stuffing-box should be refilled with flax packing.

Hoisting cables will need to be shortened occasionally as they lengthen with wear. This will be determined by running the car to the upper floor and observing whether it comes flush with the floor or falls short. Cutout, operating (or tiller) and governor ropes should be inspected weekly, because much damage can be caused by the failure of any one of them. The practice of relying on the insurance inspections, occurring as they do about once in three months, is very bad.

Phosphor-bronze is the best material for the main operating valve, as a soft brass one will soon wear to a shoulder from the constant rubbing back and forth, and these valves should be purchased as unfinished castings so that the small holes can be drilled in as desired. The brass bushings in the pilot valves will require to be renewed occasionally and of course must be made a driving fit.

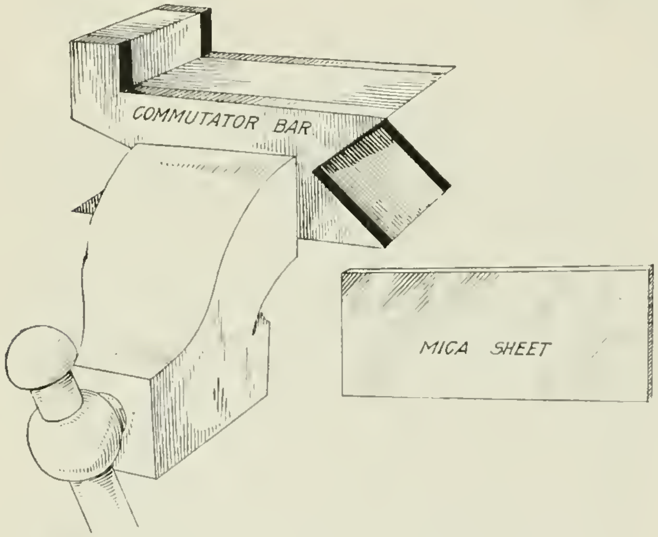
Of the safety devices on elevators, there is one that I believe should be especially mentioned, and that is the valve lock that prevents the car from being moved if any gate in the shaft is open even a fraction of an inch. Many accidents occur at the gates, as the operator is prone to start the car first and shut the gate afterward, but with this device in operation the car remains stationary until the gate is closed. It will not, however, prevent a car from settling or creeping, as that is caused by defects before mentioned, but it does prevent the operator from starting the car before closing the gate.

The surge tank will need a thorough cleaning out about once a year to keep the system clear of dirt, etc., that may lodge in the pilot valves and cause serious trouble. W. T. Osborn.

Newark, N. J.

Cutting Mica for Commutators

The following may help someone in a small shop, who has the job of cutting mica for refilling an old commutator. In a good many shops the practice is to take one of the bars, lay it on a single piece of mica, mark it off with a scriber and then cut it out with a pair of shears. A much quicker and more accurate way is to cut the mica in pieces slightly larger than the bars, then clamp about a dozen of these sheets between two of the bars in a vise and saw out to approximately the shape with a hacksaw and finish the dressing with a file.



MICA SHEETS CLAMPED FOR FINAL SHAPING

Stone, Ky. J. E. May.

A Wooden Tank Repaired

A wooden water tank on the roof began to leak, and it was found that some of the planking was decayed at the tongue-and-groove joints.

It seemed that the old tank had seen its day and would have to be replaced, but one of the maintenance men suggested that it be emptied, cleaned, dried out and lined with portland cement. Lathing nails were driven all over the inside walls at about six-inch intervals, leaving each nail head projecting about one-quarter inch, after which the whole interior was plastered over, about three-eighths inch thick, and when set, the surface was washed over with a thin coating of clear cement a couple of times.

The result was gratifying, for the tank is tight, and there are no signs of further deterioration.

Concord N. H. Charles H. Willey.

Gas Engines of Former Times

In going over our data file recently, I found a letter from a man in Pennsylvania who was using a gas engine, and I am sending you an exact copy, thinking it may be of interest, as indicating the status of gas engines at that time, the kind of service to which some were put, etc. Seventeen years have shown remarkable development in equipment of this kind.

Newark, N. J. N. A. Carle.

.... Opera House
.........., Pa., July 30, 1900.

To united Electric Company of New Jersey

Gentle Men Yours of July 27 received In regard to Gas Engines I have used automatic Gas Engine for running Dimo to Light my Opera house last winter 25 horse Power I got 300 lights I got 15 Kilowatt Dimo I had good steady light Engine run from full load to no load you now Opera house Lighting To hard on Engine we go so many dark cein we would have on 300 lights and then we would have nothin. I use natral Gas Cost me 20 cents Per thousand avrige cost Per night of run of 10 hours 27 cents Repairs on Engine for 7 months $5.67 all the Engine want is care no experimenting with It and It will work all right I consider the Engine as a hole a good one

Now for Its disinantiges It Is hard Engine to Start I have been starting mine with Powder and It Is dangerous and leavs a bad smell In house your Electric Spark must be Perfect and your Storige battry must be all right the battries I got with Engine Is now Plaid out there was 4 cells I wish you would send Me the adress of some good firm I will have to have Storige battries before I star up again I am goaning to Put In a air Pump & Tank and Start It with air this season the Engine cannot be started By hand there Is a saving to Me of about 60 Dollar Per month I consider the Engine will Pay for It self In 3 years we run the Engine 280 revelutions Per minut we get Explosing Every time If you want to now any other Point about It let me now and I will Try and Explane It as well as I can

Yours Truly, ...

Sucking from a Condenser

In reply to Mr. Baer's request, on page 807 in the issue of Dec. 11, for a sketch and description of how an engine could suck up a cylinderful of water from the condenser, I will say that I cannot furnish a sketch of the piping as I have been away from the plant for some time and cannot get a correct sketch of it. Maybe I was in error in saying the engine sucked up a cylinderful of water, for the least little bit over clearance volume is enough to wreck the engine as water is practically incompressible.

The condenser was an old-time Conover with vertical pumps working on the same shaft. The circulating water also sealed the condenser, and when the latter was shut down and the circulating water not shut off, the steam could not exhaust and was condensed, and when the engine made a return stroke the water was sucked back, or a portion of it, owing to the vacuum not being entirely gone. W. H. Nostan.

Philadelphia, Penn.

Inquiries of General Interest

Dry Materials for Extinguishing Fire—What material could be used in dry powdered form for extinguishing fire? L. S. E.

Pulverized bicarbonate of soda (baking soda) or pulverized salt is a good material for extinguishing fire. Dry sand is a good material for smothering small oil fires.

Lengths of Splices for Leather Belts—What is the rule for the length of splices for leather belting? W. R. K.

For belts up to 10 in. wide, make the splices 10 in. long. Belts that are 10 to 18 in. wide should have the splices as long as the belts are wide. Eighteen inches is the greatest length required for the splice of a double belt.

Steam Cylinders for Compound Duplex Pump—A compound duplex steam pump of 12-in. stroke and having 8½-in. water cylinders is to work against a discharge pressure of 180 lb. per sq.in. What should be the sizes of the high- and low-pressure steam cylinders if exhaust takes place against 2 lb. pressure above the atmosphere? G. R. W.

With ordinary clearance and other proportions of design, each side of the pump should have a 9-in. diameter high-pressure and 15½-in. low-pressure steam cylinder.

Rating Boiler Size on Heating Surface—In rating boiler horsepower according to the number of square feet of heating surface, is not superheating surface to be included? L. G.

The horsepower rating according to heating surface is purely commercial. Water-heating surface, or surface in contact with fire or hot gases on one side and water on the other, is very effective in transmitting heat, and this is the principal kind of heating surface in nearly all types of boilers and in most boilers it is the only kind. The heat transmission through superheating surface which has fire or hot gases on one side and steam on the other side is very slow, and it is not customary to count in this kind of heating surface in rating the nominal or manufacturer's horsepower of a boiler. The superheating surface should be separately stated as such.

Air Gathered in Feed-Water Oil Filter—The returns of a vacuum steam-heating apparatus are delivered to an air-separating tank and thence discharged to a receiver and boiler-feed pump. After being discharged by the pump, the return water, on its way to the boiler, is passed through a cloth-bag filter for removal of the oil. Air collects in the upper part of the filter. What is the cause and remedy for removal of the air gathered in the filter? G. G. W.

It is probable that the "air" complained of consists of oil vapor and air liberated out of the water when the pressure of the water is suddenly reduced, after being subjected to the greater pressure necessary for forcing the water through the filter. If it is permissible to have a small air space in the top of the filter, the air or vapor can be relieved automatically by connecting a float type of radiator air valve with the upper part of the filter chamber, or with an appropriate enlargement of that space by employing a small air chamber made of pipe and fittings.

Advantages and Disadvantages of Steam Dome—What are the advantages and disadvantages of providing a horizontal return-tubular boiler with a steam dome? L. D.

The advantage of a steam dome on a boiler is that it increases the volume of the steam space and allows the steam to be taken from the boiler at a point somewhat removed from the surface of the water, thereby insuring a supply of drier steam than if the supply were taken directly from the shell. The leading disadvantages are the added expense, difficulty of making and maintaining safe and tight connections of the dome with the shell and the uncertain weakening effect of the dome opening on the shell. The advantage of obtaining drier steam can be met, however, by a good form of dry pipe or separator placed within the shell or by employment of an exterior steam drum. A steam drum with nozzle connection to the shell is usually less expensive than a dome, and besides affording the opportunity for much safer construction has all the advantages without any of the disadvantages of a dome, excepting the requirement of practically the same if not less headroom.

Independent Stacks for Horizontal Return-Tubular Boilers—For a suburban factory power plant, begun with the installation of two horizontal return-tubular boilers that probably will be duplicated within a year, would it be better to supply each boiler with a separate steel stack set over the uptake, or provide a steel stack that will be adequate for all boilers? J. B. N.

The best draft control would be obtained by furnishing each boiler with a separate stack, but placing the stacks directly over the boiler uptakes is objectionable on account of the expense of providing supports suitably independent of the boiler settings and trouble will be experienced from soot and scale dropping from the inside of the stacks into the uptakes of the boiler. The arrangement also would be likely to give trouble from rain water running down the sides of the stacks and finding its way to the boiler settings. These disadvantages can be obviated and nearly the same draft advantages of independent stacks can be secured by setting the stacks at the sides of the settings or to the rear of the firing spaces, and providing the connections from the uptakes to the separate stacks with easy bends. For most situations the independent stack supports and connections should cost no more than proper provision for independently supporting the stacks directly over the uptakes of the boilers.

Sufficiency of Chimney Draft—Trouble is experienced in burning sufficient coal and keeping up steam in two return-tubular boilers each 72 in. in diameter and containing 92 tubes 3½ in. diameter by 18 ft. and with breechings connected to a brick stack 48 in. in diameter at the smallest part and 80 ft. high. Is the chimney size at fault, or if not, what may be the cause of the trouble? W. K. C.

The rated size of each boiler is about 150 boiler horsepower. Allowing for combustion of 5 lb. of coal per boiler horsepower, ordinary form of breeching and other smoke connections, a fair quality of fuel and proper firing, the chimney should be adequate for about 310 boiler horsepower or ample for the boilers. It may be that the draft is impaired by proximity of high hills, or that air enters cracks or opening in the chimney flue or connections. The size and form of the connections from the boilers may be at fault for realizing the draft effect of the chimney. The uptake from each boiler should have an unobstructed cross-sectional area of not less than 775 sq.in. The cross-sectional area of the breeching and connections to the chimney should be not less than 1600 sq.in.; the breeching should be provided with a baffle for carrying the smoke of the boiler farther away from the chimney over or around the uptake of the boiler nearer the chimney,and the breeching connections, especially the junction with the chimney flue, should be beveled or curved to admit of easy passage of the gases.

[Correspondents sending us inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—EDITOR.]

The Failure of Boiler Plates In Service[*]

BY E. B. WOLFF[†]

The author's investigations show that peculiar cracks in boiler plate occur at the riveted joints in all boilers examined. These cracks are found on the inner surfaces of the rivet holes or on the surfaces of the plates where they are held together. The cracks are due to fatigue.

THIS research was undertaken with the view of finding the causes of the cracking of boiler plates over the riveted seams.

The boilers were of the single-ended ordinary marine type, with three flues. The shell plates and the rivets were generally approximately 32 mm. (1 in.) thick, made some from basic and some from acid openhearth soft steel with an ultimate tensile strength of 42-48 kg. per square millimeter (59,700 to 68,000 lb. per sq.in) and an elongation of 23 per cent. to 20 per cent. on 10 diameters. The phosphorus and sulphur contents had to be under 0.05 per cent. Most of the boilers with the cracked plates belonged to steamship companies, the boats of which made voyages with a great many stops, so that the fires were frequently extinguished and relighted. Most of the boilers being oil-fired, this could be done very easily. The plates of coal-fired boilers, however, cracked in the same manner. Boilers made of the same material for other companies, the boats of which had only long nonstop runs, did not fail.

CRACKS AT FIRST OF MICROSCOPICAL DIMENSIONS

All the cracks found are, in the beginning, defects of microscopical dimensions. After having increased in length and breadth, they could be detected. It would occur that a boiler, the side seam of which had failed, would be sent back to the boiler shop to be fitted with a new shell plate. After detaching the front plates, nothing abnormal would be seen, and it would be decided to make use of the old front plates and fit new shell plates to them. The shell plates were bent with great care to the radius of the front plates and bored in position. When the first rivet joining the front and shell plates was put in, cracks appeared in some of the old rivet holes of the front plate. By a renewed examination of the other rivet holes, after cleaning the metal by scraping it carefully and later etching it, minute cracks were detected. The etching of the front plate, in the manner presently to be described, disclosed a great many miniature cracks, so that it was impossible to use it any more.

As already stated, the cracks were found in the butt joints as well as in the lap joints, but in all cases they started either from the inside of the holes, in two places, where the highest tensile stress occurred, or at the surfaces of the plates, where they were pressed on the surfaces of other plates. The fact that cracks start frequently on the inner surfaces of boiler plates has been mentioned by several investigators,[1] but a good indication of the causes has not been given.

The cracks cover a certain part of the surface, depending on the direction of the stresses that acted on that part. Where they are found in the rivet holes of the plates, they occur generally on two sides of the holes; in the case of the pipe holes of the tubular boiler, they spread from the top of the hole inward. When they occur on the surface of the plate, it is in general mostly around the rivet holes, but also in other places.

As mentioned, the cracks start as miniature surface cracks of microscopical dimensions; it appears that every little crack has been formed by itself, without the slightest reference to its neighbors. A polished and etched section through these cracks shows that the crystallites in the immediate neighborhood have not been deformed. The structure of the material has in most of the cases been found quite normal, no free cementite being present. Afterward the cracks grow in length and depth, and unite in longer ones, forming a peculiar stepped line.

PECULIAR DESTRUCTION OF SURFACE LAYERS

All evidence points to a peculiar form of destruction of the surface layers of otherwise very plastic metal. As the cracks always started at the surface of the metals and in the holes over the entire thickness of the plate, phosphorus or sulphur segregations, if these had occurred, could have had no influence. No segregations of importance were, however, found in most of the cracked plates. At first it was thought that the deformation of the material in the rivet holes made by the boring of these holes might have had a great influence. As it was not possible to produce similar cracks in holes that were bored with a blunt drill, and as pieces cut out of such a hole and bent open till the deformed surface broke showed sufficient deformation before breaking, it was concluded that if the deformation had been one of the causes, it could only have been a secondary one. As hand-riveted joints cracked in exactly the same manner as joints where the rivets had been pressed in by the hydraulic riveting machine, the pressure of this machine on the plate also cannot be the cause of the cracking.

Parts of the cracked plates, where no cracks occurred, were tested by joining them by rivets, driven in with the maximum pressure the press could give. Afterward the rivets were taken out and the plates examined and bent. Here a great deformation of the surface also preceded the rupture.

To reveal the miniature cracks it was found necessary to etch the metal with dilute sulphuric acid (1 : 10) during twenty-four hours or more. Before this etching the cracks were covered by the surface oxides, and they could not even be detected after scraping the plates thoroughly. It was necessary to ascertain that this etching did not cause similar cracks. It was found that in no case of deformation could cracks be seen after etching, not even if the metal were left in the etching solution for an abnormally long time. The deformed places were corroded in most of the tests before the rest of the metal, but this corrosion never caused sharply defined cracks. By an abnormally long immersion the deformed places could not be differentiated from the neighboring metal; the cracks, however, showed very clearly. Microscopical sections through nonetched parts showed that the cracks were clearly to be seen without the aid of an etching solution.

Some parts of plates from other seams of the cracked boilers did not even show cracks after prolonged etching.

ETCHING AN AID IN DETECTING BAD PLATES

The etching with sulphuric acid has been of great aid in detecting the bad plates from those that could be used again. It dissolves the metal quite regularly and discloses even the finest cracks. The only phenomenon known where cracks of the kind described have been observed in plastic material is that known as "fatigue." The beautiful researches of Ewing and Humfrey have disclosed the mechanism of the formation of these very local hair-cracks in plastic metal. A case of the formation of similar cracks in a large shaft, where overloading in service could be proved, showed quite the same kind of cracks after etching with diluted sulphuric acid.

Photomicrographs show that the crystallites in the immediate neighborhood of the crack were not deformed. This

[†] Bussum, Holland.

[1] C. Sulzer, "Wärmespannungen und Ritzbildungen," "Zeitschrift des Vereins deutscher Ingenieure, 1907. Report by the National Physical Laboratory of an investigation of some unusual defects in the plates of two combustion chambers on board a foreign-going passenger steamship, and note by the engineer-surveyor-in-chief; "The cracks themselves were unusual, as they appear to have started at the inner surfaces, where the plates were laid together for riveting, and were invisible until extended through the plates." —"Engineer," 1910

was also the case with the boiler-plate cracks. These parts in the boilers being subjected to stresses of such magnitude, it may be asked how it is that the few alternations during the lifetime of a boiler can cause these cracks. It may be observed, in the first place, that the ships with boilers that have cracked made relatively short voyages along the coast, and that in the beginning no care was taken to avoid changes in the steam pressure. When, later, care was taken to maintain the steam at a regular pressure, the cracking diminished, but did not stop altogether. The first boilers were oil-fired and were made of basic openhearth material; afterward boilers, both oil- and coal-fired, made of first-quality Scottish acid steel, cracked in the same manner. Notwithstanding the severe conditions of the service, the number of the alternations is, however, only few when compared with that required to produce ordinary fatigue breaks. Only when it can be proved that at the places where the cracks are found abnormally high stresses can occur, may we accept "fatigue" as the cause of these cracks. It was necessary, therefore, to start an investigation of the stresses occurring in these parts of a boiler.

It is known from the theory of Kirsch and Leon and the tests by Preuss that the tensile tension at the edges of a hole in a bar loaded in the direction of its axis may amount to three times the average tension calculated for that bar. When it can be proved that the holes of a riveted joint can behave as in ordinary bars, we have an explanation for the fact that the tension at the edges of the holes can reach a very high value. The average tensional stress in the cracked plates was approximately 11 kg. per mm. When this value is trebled we reach such a high stress in these places that very few alternations will suffice to cause a crack. It is thus necessary to prove that the friction between the plates will not be sufficient to counteract the deformation of the sides of the holes.

USING SPECIAL TYPE OF EXTENSOMETER

With a view of testing this, and to learn the values of the local stretch in different places of the surfaces of the plates that are pressed against each other, the author has made use of a special type of extensometer, designed by Mr. Okhuizen.

It consists of two knife-edges that are pressed to the surface where it is sought to ascertain the elongation as a measure of the stress. The change in the distance between these edges, one of which belongs to the fixed part, the other to a movable one, can be read from a scale by means of a simple arrangement of levers.

The Lap Joint—It can be clearly seen that although the plates are pressed together by the rivets, the material of both plates shows a similar elongation only in the immediate neighborhood of the rivets. In all other places the elongation is different, so that the surfaces move along each other.

It can be seen that the load is more or less gradually taken over from the shell plate by the cover plates; the gradual change will be different for every vertical section through the joint, depending on the position of the neighboring rivets in relation to the section and on the pressure of these rivets on the plates.

Photomicrographs of the separation line of the two plates disclose that in those cases where the plates have been cleaned before riveting by scraping them with a stiff brush, as in normal practice, the metallic parts do not come together, but are separated by a very compact layer of some sort of oxide. This layer has irregular breadth, the surface of the plate being very irregular under this magnification. When elastic displacements of the plates occur of the magnitude demonstrated, we can easily accept the supposition that stresses will hereby be caused high enough to explain the cracking of the plates.

P. D. Merica[2] has published the results of an investigation on the embrittling action of sodium hydroxide on mild steel and its possible relation to seam failures of boiler plate. The conclusion drawn is that the influence of alkali on steel can be detected principally by means of the alternate bending test, the number of alternations being some 20 per cent. lower for the metal treated by the alkali than the values for the untreated metal. A recovery of the material occurs after a week's time of treatment at the temperature of 180 deg. C. (356 deg. F.).

I should like to observe, in the first place, that the same kind of cracks mentioned in the present paper was found by Mr. Merica in different kinds of boilers; that the cracks described by me have occurred not only in the water space, but also in the steam space of boilers; that the cracks being extremely local, in most cases no leakage was observed and no boiler scale was found between the plates; that as the boilers crack after having been in service for one or more years, recovery of the material from the effect of the alkali, mentioned by the author, should have taken place long before the cracks started.

Baltimore Encourages Fuel Economy

Baltimore, despite its proximity to the coal fields, and that it is a great coal-distribution center, suffers in common with other Atlantic coast cities from shortage of coal. The water power available, chiefly from the large station at McCalls Ferry on the Susquehanna River, has prevented such extended interruptions of service as more northern localities have experienced.

Recognizing the need not only of interesting the industries in fuel economy, but of discussing specific measures to achieve it, the Baltimore Section of the American Society of Mechanical Engineers, the Engineers' Club and the City Club held the first of a number of large meetings at the City Club, Thursday evening, Jan. 10. The meeting was made possible chiefly through the efforts of Prof. A. G. Christie, of the engineering department of Johns Hopkins University. Harry D. Bush, president of the Engineers' Club, presided. Besides many plant owners and managers and professional engineers, there was the largest gathering of operating engineers and firemen that ever came together in a local meeting, it was said.

The main address was made by Charles H. Bromley, associate editor of *Power*, and that part of it directed particularly to firemen and the operating men appears on page 146 of this issue.

Mr. Bromley said that while the many efforts made to educate the fireman would doubtless do good, it was his opinion that because of the urgency of coal saving, the best way to meet the situation was the payment of bonuses to the boiler- and engine-room crews for coal saved. The most suitable method of bonus is not to be expected at first, but some form may be used in the beginning and perfection developed as the result of experience gained. The speaker regretted that it was not possible to give more than the fundamentals on which to base a bonus system, declaring that an equitable bonus for a particular plant required particular study. The fundamentals, he said, were, first, the ease with which saving could be effected; second, the magnitude of the saving; and third, the number of persons to participate in the bonus. In conversation subsequent to the meeting Mr. Bromley said he believed the rate of payment in bonus should be based either upon the weight of coal saved per unit of output or upon the price per unit weight of coal saved per unit of output.

The speaker urged manufacturers and plant owners to inquire into the equity and adequacy of the wages paid their power-plant employees, declaring that there is no small measure of unrest among engineers and firemen. It would be well, he said, to inquire if it would not be well to anticipate organized effort on their part to secure fairer remuneration. Engineers, on the whole, have not organized in a labor way, having faith in the "learn more, earn more" slogan. The employer would do well to strengthen this faith rather than weaken it.

The fuel crisis has lent great impetus, Mr. Bromley said, to the use of the lower grades of coal, and although the engineers and firemen of Baltimore scorned hard coal, it is likely that they, in common with men of other sections of the country, must learn to burn mixtures of the Somerset semibituminous, widely used in Baltimore, and culm.

It is the speaker's opinion that the advantages of operating engines and turbines on a compromise back pressure are not widely enough known or thought of by those in-

---

[2] "Metallurgical and Chemical Engineering," May, 1917.

stalling power plants for mills, buildings, etc. With compromise back pressure the engine or turbine is operated condensing, the condenser being "hooked up" to the return of the heating system, while the steam supply to the heating system is taken off the main exhaust steam line between the unit and the condenser, with a valve to control the steam flow. The back pressure on the engine is varied from the most economical vacuum, say 26½ in. in summer to, say, 1 lb. gage during extremely cold weather. Mr. Bromley referred to the Mar. 27, 1917, issue of *Power*, in which he described, with drawings, an installation of this kind at the Lynn (Mass.) Realty Co.'s buildings. The extraction turbine offered similar possibilities, said the speaker.

Following Mr. Bromley, George Goodwin, engineer at the Sheppard-Pratt Institute, representing the American Association of Steam Engineers, spoke on coal saving by care in ventilating buildings. John Powell, of the International Association of Steam Engineers, encouraged the use of combustion and other appliances for saving coal. Charles L. Mintien, of the National Association of Stationary Engineers, advised the consolidation of the various engineers' organizations that better educational and conservation measures might be made possible to the engineers of Baltimore. John Milne, inspector, United States Steamboat Inspection Service, encouraged saving in the small boats that ply the shore and harbor. Robert Mugford, chief engineer, Monumental Brewing Co., pointed out how licensing and examining of engineers would promote economy in power-plant operation. Philip Kirkwood, of Sharpe & Dohne, spoke on firing methods.

Prof. A. G. Christie, of Johns Hopkins University and secretary of the Baltimore section of the American Society of Mechanical Engineers, through whose efforts, chiefly, the meeting was brought about, spoke briefly, saying that if Baltimore could save 15 per cent. of its usual consumption of coal, it would amount to over $2,000,000 per year.

Captain Webster, of the Ordnance Department, gave a few rousing remarks, in which he said that it required about four pounds of coal to get one pound of steel in the form of shells to where it would do the most damage to the Germans.

The Engineer's Public Duty

In the course of an address before the New York Chapter recently, President Edmund T. Perkins, of the American Asosciation of Engineers, said:

There are 56,000 engineers enrolled on the membership lists of the various engineering societies of the United States. This easily indicates a total of 100,000 engineers in active practice throughout the United States. The profession has existed and been recognized for centuries and shows a remarkable growth in numbers engaged therein, but unfortunately does not show an equal growth in position and standing in the community, for the engineer has been too much engaged with the complex problems that arise in his daily labors, to reflect on the part he has actually played or should play in society.

It has been said that the engineer is all head and no heart. This may be true of the composite head and heart of the engineering profession, but there is no more companionable, congenial, lovable man among his familiar associates than the engineer.

Now, while the engineer himself is to blame for his present position, a greater amount of blame can be attached to our engineering organizations and societies. For with the exception of the American Association of Engineers, there has not been one engineering organization or association which deals with the human side of the engineer. This one exception has awakened to the fact that engineers are not occupying their rightful position of usefulness. Engineers have considered politics as undignified and corrupting. It is true that there are corrupt politics, but this is so because men who should have kept them righteous have stood aside. There is no class of educated people more bound to traditions than the engineer. No one has made slower progress toward collective efficiency. We must join together, we must coöperate in working out reforms. A technical education never made a real engineer; 40 per cent. of his work has to do directly with humanity rather than with technicalities.

In the past the trouble has been too much modesty—too little public interest; too much independence—too little coöperation; too much technicality—too little humanity; too much aloofness—too little goodfellowship.

The engineer of tomorrow, if he is to assume and maintain the position in society that his past achievements entitle him to, must become a man of larger sympathies and wider visions. He must play more and work less by himself. He must aspire to hold the honorable offices of the state, that he may administer them for the public welfare. He must be an arbiter, not an advocate, and he must have for his watchwords, Service and Coöperation.

Electric Motors for Ammonia Compressor Drive

The largest meeting yet held by the New York Section of the American Society of Refrigerating Engineers occurred Tuesday evening, Jan. 15, at the Machinery Club, 50 Church St., New York City. About sixty were present. The section has forty members, all of whom are members of the American Society of Refrigerating Engineers, the parent body. At the yearly meeting of the parent society in December, changes to the constitution were proposed to allow local sections to have affiliated members who are not members of the parent society. This amendment will likely pass at the next yearly meeting, and in the meantime the New York Section will take in affiliated members, refunding their dues of $6 per year if adverse action is taken on the amendment at the parent society's meeting next December.

The question of a suitable emblem for affiliated members came up for considerable discussion, but was left open.

A committee of three will be appointed by the president to assist the A. S. R. E. Subcommittee on Refrigeration in the Council of National Defense. F. E. Matthews and Henry Torrance are the members of the parent society serving on this subcommittee.

The nominating committee, consisting of F. E. Matthews, William Ross and Karl Zesterdahl, nominated L. Howard Jenks, New York manager of the Frick Co., president of the section to succeed John E. Starr, whose term expires. Mr. Jenks has been acting president during nearly the whole year, Mr. Starr having been and still being ill. Mr. Jenks was elected. The secretaryship was left open on the expiration of the term of Van R. H. Green. Charles Herter, who has been acting secretary during most of the year, was requested to continue as such. Mr. Herter is responsible for much of the success of the section's meetings.

Without attempting to criticize, President Jenks emphasized the need of greater thoroughness in drawing up specifications for refrigerating apparatus specified by the Government for various purposes. The sixteen specifications now circulated show the need of the application of engineering attention, suggested Mr. Jenks.

W. J. Moore, of the New York office of the General Electric Co., requested that some disinterested member check over test results of and examine some small refrigerating machines about to be shipped to France for the Red Cross hospitals and food bases. The Red Cross has asked some of its members connected with the New York office of the General Electric Co. to ship these machines. The examination would, of course, have to be gratis. President Jenks appointed Fred Ophuls to give his services, which Mr. Ophuls expressed himself as most willing to do.

Suggesting papers desirable for presentation before the section, Mr. Herter reminded President Jenks that Adolph Koenig promised a paper on brine-circulating systems; that Harry B. Joyce, of the United Electric Light and Power Co., New York, promised one on electric drive for ice plants; F. L. Fairbanks, one on high-speed compressor valves. Mr. Herter said that Mr. Dickerman, of the De La Vergne Machine Co., would be pleased to present a paper on ice storage.

F. J. Bartlett, of the Electric Machinery Co., 161 Devonshire St., Boston, Mass., read a paper on the synchronous motor for ammonia compressor drive. Following are the chief points brought out by Mr. Bartlett.

Compressor design has followed closely the development of the compressor prime mover. The very slow machines of years ago were driven by long-stroke engines; the Corliss engine increased speeds somewhat, while a marked increase in speed has been brought about by direct motor drive, aided by the introduction of the high-speed plate valve of low lift for the compressor. The plate valve is good for speeds up to 240 r.p.m. About 40 per cent. is saved in floor space and headroom by use of the high-speed, motor-driven compressor. While direct drive is usually desired, Mr. Bartlett recognized that belted motors are sometimes necessary.

The speaker aimed to show that for motors of similar horsepower and speed, the full load efficiency of the synchronous motor was appreciably higher than that of the induction motor by 5 to 10 per cent., although he gave a general statement of 15 per cent. difference credited, he said, to a handbook distributed by the Condit Electrical Manufacturing Co., of South Boston. Mr. Moore said such a difference was very much too high and was not true of average standard motors of both types. Mr. Bartlett agreed with Mr. Moore.

In the past objection has been raised to the synchronous motor because of the separate excitation required. Advance in design has eliminated this objection, said Mr. Bartlett, and experience has shown that exciter troubles are not even serious enough to be a factor.

Air compressors are now without flywheel effect other than that given by the rotor of the motors driving them. This does not mean that ammonia-compressor builders should strive to eliminate the flywheel; but it is likely that they will find it advantageous to cut down the weight of flywheel used. The reason for lightness of flywheel is to reduce the starting torque.

The air gap in the induction motor is smaller than for the synchronous motor; therefore wear of the bearings may be greater without fear of mechanical and magnetic troubles.

The central station more and more demands that its distribution lines be working at high power factor. Because the synchronous motor gives unity power factor, its use is highly desirable from the central-station standpoint. Considerable emphasis was laid on this point by those discussing the paper, the substance of their remarks being given farther on in this report.

Mr. Bartlett hoped that there would be the closest coöperation between the manufacturers of motors and the builders of ammonia compressors.

DISCUSSION

J. W. Moore, General Electric Co., New York City: Relative to the efficiencies of the two types of motors a synchronous motor of 600 r.p.m. and 200 hp. had an efficiency of 94 to 94½ per cent., and a slip-ring induction motor of the same speed and capacity would have an efficiency of 89 per cent. This represented the difference in efficiency to be expected usually.

J. C. Carpenter: It should be pointed out that the power factor would have to be considerably sacrificed to design an induction motor which would have characteristics similar to a synchronous for the same purpose.

Air-compressor builders have gone through the experience of induction and synchronous motor drive, and they have widely adopted the latter type of motor. For air-compressor drive the synchronous motor requires, to give a broad figure, about 30 per cent. with about 15 per cent. pull in. It is not certain that the ammonia compressor will take as much. Mr. Carpenter also urged the motor manufacturers and builders of ammonia compressors to come together.

Charles D. Neeson suggested that the section seek a paper dealing with results found in experimental work to be done by the motor and compressor builders some time during the year. He urged that the central station present its suggestions and claims in the same paper. The matter was left open other than that President Jenks appointed Mr. Neeson to get such a paper before the section.

J. W. Moore: Four years ago the first electrically driven ice plant in this section was installed on the plant of the Syracuse Ice Co. Much had been learned from this installation, and the chief thing it taught, Mr. Moore believed, was that the best plant is one that can use standard apparatus "taken from the shelf." The belted induction motor was the only logical motor at the time the Syracuse plant was built.

As showing the growth of the synchronous motor for air and ammonia compressor drive, he said that during 1917 motors to the number of 177, aggregating more than 65,000 hp., had been sold by his company.

It is Mr. Moore's belief that a compressor of speeds up to 500 r.p.m. is yet to come, and will come, and that when it does, the induction motor will be more suitable as the prime mover than the synchronous motor. Between 350 and 500 r.p.m. the controversy as to which motor is most suitable is chiefly one around the questions of simplicity and efficiency.

Harry Joyce (United Electric Light and Power Co., New York City): It is customary in this locality for the consumer to pay for the transformer losses. These are so very much greater with the induction motor than with the synchronous that it is of vital concern to the consumer. The time is not far distant when the central station must compel the consumer to stand the costs occasioned by low power factor.

Mr. Hill, of Ophuls, McCreery & Hill, consulting engineers, New York, pointed out that for the same service an induction would cost more than the synchronous motor. He also laid emphasis upon high power factor as desirable to central station and consumer, stating that a line loaded to 80 per cent. power factor gave 20 per cent. less return on the investment than was true for unity power factor, meaning return to the company selling power.

The section requested Charles H. Bromley, associate editor, *Power*, to give a paper on "Specific Fuel Wastes and Their Reduction," at the next meeting, Mar. 19. Mr. Bromley will give such a paper.

Ordnance Department Needs Civilian Workers

The Ordnance Department urgently needs several thousand civilian workers to serve in the United States. The Civil Service Commission is conducting an extensive campaign to obtain this needed help. Among the positions to be filled are the following:

Clerical Positions: 2000 stenographers and typewriters, men and women, $1100 to $1200 a year; 2000 typewriter operators, men and women, $1100 to $1200 a year; 2000 general clerks, men and women, $1100 a year; 500 index and catalog clerks, men and women, $1100 to $1200 a year; 200 clerks qualified in business administration, $1200 to $1500 a year; 300 schedule clerks, men and women, $1400 to $1600 a year; 300 production clerks, not more than $1500 a year; 200 clerks qualified in statistics or accounting, $1100 to $1800 a year; 100 statisticians, $1800 a year; 100 multigraph operators, men and women, $1000 to $1200 a year.

Testing Positions: 200 engineers of tests of ordnance material, $1500 to $2400 a year; 200 assistant engineers of tests of ordnance material, $1000 to $1500 a year.

Mechanical Trades Positions: 2500 machinists, $4 a day; 500 machine operators, $2.75 a day; 200 drop forgers, $5.75 a day (piecework); 300 tool makers, $4.50 a day; large numbers in practically all other trades.

Drafting Positions: 500 mechanical draftsmen, $800 to $1800 a year; 50 gage designers, $2000 to $3000 a year; 100 apprentice draftsmen, $480 a year.

Inspection Positions: 300 inspectors of small-arms ammunition, $1500 to $2400 a year; 100 inspectors of artillery ammunition (high-explosive shell loading), $1500 to $2400 a year; 100 inspectors of artillery ammunition (forgings), $1500 to $2400 a year; 100 inspectors of artillery ammunition (ballistics), $1500 to $2400 a year; 300 inspectors of field artillery ammunition steel, $1500 to $2400 a year; 300 assistant inspectors of field artillery ammunition steel, $3.50 to $5 a day; 500 inspectors of small arms, $1500 to $2400 a year; 100 inspectors of material for small arms, $1000 to $1800 a year; 100 assistant inspectors of cannon forgings, $1500 to $2400 a year; 100 assistant inspectors of finished machine parts, $1500 to $2400 a year; 100 assistant inspectors of gunfire-control instruments, $1200 to $1500 a year; 50 assistant inspectors of steel helmets, $1000 to $1800 a year; 50 assistant inspectors of cleaning and preserving materials, $1000 to $1800 a year; 400 inspectors and assistant inspectors of powder and explosives, $1400 to $2400 a year.

Salaries named are the usual salaries at entrance. Higher or lower initial salaries may be paid in exceptional cases. Positions paying salaries higher than those named are usually filled through promotion.

Men only, unless otherwise specified.

For further information apply to the representative of the United States Civil Service Commission at the post office or custom house in any city, or to the Civil Service Commission in Washington, D. C. Except for the positions of stenographer and typewriter, typewriter operator, multigraph operator, and general clerk, applicants are not assembled for a written examination, but are rated principally upon their education, training, and experience, as shown by their applications and corroborative evidence.

Fuel Economy in Private Generating Plants

Engineering Offices
PERCIVAL ROBERT MOSES, E. E.
366 Fifth Avenue
New York, Jan. 15, 1918.

Mr. Albert H. Wiggin,
State Fuel Administrator,
61 Broadway, New York City.

Dear Sir—My attention has been called to your circular letter, addressed to owners and operators of private electric generating plants.

I do not think it is possible that my letters on this subject have misled you, because I have tried to be very clear in bringing out the fact that fuel economy can be obtained by operating the private plants to their limit during such part of the year as their exhaust steam can be used for heating.

If you will call up any one of fifty private-plant owners in your immediate vicinity, you will find that practical experience has shown them that they will use no more coal during the months of January, February and March, and in many cases also in April, for supplying their total requirements of heating and electricity than they would for supplying their requirements of heat alone. This is such a well-known fact that it is hardly disputed by unbiased engineers.

Mr. Bion J. Arnold, the great exponent of central plants, who is now a major in the United States Army, stated the other night at the American Institute of Electrical Engineers that there could be no question that the private generating plant using its exhaust steam was the most efficient method of producing electricity.

I would suggest that you call up Mr. Harris A. Dunn, of the Columbia Trust Co., whom you probably know, and ask him for his experience. In that building, the actual coal used in two successive years—one buying Edison current, and the other making the current—was less when the current was made than it was when the current was bought.

The same thing was true in a test we made in the Mutual Insurance Co.'s building in Richmond, and you will find that this is the universal experience.

I would like very much to come down and have a talk with you about this matter, and explain exactly what I did mean in my previous letters.

Yours very truly,
P. R. Moses.

Research Fellowships

At the end of the academic year there will be 12 vacancies in the 14 research fellowships maintained by the University of Illinois. Two other such fellowships have been established under the patronage of the Illinois Gas Association. These fellowships, for each of which there is an annual stipend of $500, are open to graduates of approved American and foreign universities and technical schools. Appointments are made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Not more than half of the time of the research fellows is required in connection with the work of the department to which they are assigned, the remainder being available for graduate study. Nominations to these fellowships, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the director of the station each year not later than the first day of February. Appointments are made in the spring and take effect the first of the following September.

As to the attitude of the War Department toward graduate students in engineering, the office of the Chief of Engineers has ruled that resident graduate students in engineering who are candidates for an advanced engineering degree may avail themselves of the privileges provided by the new regulations, under which engineering students may be enrolled in the Enlisted Reserve Corps of the Engineer Department and placed on the inactive list until they have completed their educational training.

Shipping Board Schools

Official announcement was made Jan. 19 by Henry Howard, Director of Recruiting for the United States Shipping Board, that under a recently issued regulation of the Provost Marshal General's department all students entering Shipping Board schools for deck officers or engineers will be exempted from military duty and will remain exempted so long as they pursue the calling for which the school fits them. This affects six hundred or more students now in Shipping Board schools and will apply to students enrolled in the future.

There are now thirty of these schools training deck officers for the merchant marine and eight training engineers. Only men who have had two years' seafaring experience are admitted to the schools. On graduation a student is either sent to sea for further training as a reserve officer in the merchant marine or is licensed at once for the grade in which he is eligible.

About four thousand new officers for the merchant marine have been licensed since the United States entered the war. The Shipping Board schools will continue to receive a limited number of students monthly, the course being one month in the engineering schools and six weeks in navigation schools.

Soldiers' and Sailors' Insurance

The Treasury Department is making every effort to have each member of America's fighting forces take advantage of the Government-insurance plan, which Secretary McAdoo asserts to be "the most just and humane provision ever made by any nation for its soldiers and sailors."

The purpose is rapidly being achieved, the insurance having passed the third billion mark in the total of policies written, and there are many military units in which every member has taken insurance.

The automatic insurance provided by the law is only partial and limited protection, payable only to wife, child, or widowed mother and ceases after Feb. 12, 1918. It is important, therefore, not only to the soldiers and sailors of the country, but to their families and dependents, that before that date they avail themselves of the full Government protection, which can go as high as $10,000 and is payable to a wife, husband, child, grandchild, parent, brother or sister.

Materials Division, Quartermasters' Corps

The following is the report of the Quartermaster's Corps, U. S. Army, Materials Division, 15th and M Sts., Washington, D. C.:

Major J. N. Willcutt in charge. Purchasing: Capt. O. F. Noss, assistants N. A. Lufburrow, J. C. McCubbin, C. G. Graves and R. T. Vaughn, buying plumbing, tank heaters and hot-water tanks; J. H. Prentiss, buying refrigerating machinery; M. O. Pinkham, buying hydrants, storage tanks, valves, wood pipe, steel pipe, cast-iron pipe and pipe fittings; E. W. Case, assistants A. F. Knibiehly and L. W. McCrea, buying ash hoists and conveying machinery; Lieut. A. C. Nell, assistant H. H. Easterly, buying pumping equipment, air compressors, rail and track materials, locomotive cranes, sprinkler systems, water meters, recording apparatus, coal and engines; Capt. W. H. Riblet, assistants S. W. Newcomb and H. Goodkind, buying heating equipment, heating boilers, heating pipe, heating tanks, feed-water heaters, boiler-feed pumps, insulating material, valves, fittings, traps, regulators and radiation; J. E. Erickson, assistants M. S. Donally and M. A. Closs, buying motors, power transformers, oil switches, switchboards, lightning arresters, series regulators, wire, electric supplies, battery-charging equipment and storage-battery trucks.

Considerable speculation has been occasioned by an advertisement which appeared on the front page of the New York *Tribune* daily for a couple of weeks, which read, "Employ Your Local Consulting Engineer," but was signed by John A. Stevens, of Lowell, Mass. It seems that the wide-awake chairman of the Boiler Code Committee got to thinking of all the coal that could be saved if everybody would follow the advice of a competent mechanical engineer, and so he ran the advertisement, hoping that it might lead to an improvement in the fuel condition by the employment, by those who might see it, of the nearest or most available consulting engineer.

New Publications

"VULCAN"

The December, 1917, issue of "Vulcan," which is the house organ of the Vulcan Steel Products Co., 120 Broadway, New York, appears in an attractive and seasonable cover. The history of steel making, another installment of which is given in this issue, is doubly interesting because of the reproduction of woodcuts illustrating early steel-working machinery. Articles on export business and a profusion of halftones round out an excellent number of this well-edited journal. Copies may be obtained free on application to the publishers.

THE OXIDATION OF COAL

Bureau of Mines Technical Paper 98, by S. H. Katz and H. C. Porter, under the title of "Effect of Low-Temperature Oxidation on the Hydrogen in Coal and the Change in Weight of Coal on Drying," gives the following as the results of the investigation:

The temperature basis of nearly all the recorded work of previous investigators of the oxidation of coal as related to the hydrogen of the coal substance was at the temperature of boiling water and above, and water was invariably produced in readily determined quantities, but three different investigators have studied the subject with regard to changes at ordinary temperatures. The results obtained by these investigators vary widely—from the statement that "quite a large amount of water is produced in oxidation" to those of the authors who can find no water produced by their method of experiment. The third investigator found that in some cases very small amounts of water were produced and in others none whatever. The authors of this paper conclude that at ordinary temperatures coal undergoing oxidation produces no water. They have also determined that the change in weight of the coal is less than that of the water removed from the coal when drying takes place in an inert atmosphere. Others have noted this discrepancy. A possible explanation is that the discrepancy results from the absorption of gas by the coal on drying.

The conclusions are: (1) There is a lack of agreement between the weight of water evolved by coal and the loss of weight when dried in an inert atmosphere; the excess weight of the coal may be due to absorption of gas. (2) A study of the vapor tension of water in coal, as indicated by the water removed by a regulated current of dry nitrogen and air used alternately, shows no production of water by the oxidation of coal at ordinary temperatures.

Obituary

C. H. Newhall, chief engineer and building superintendent of the Chamber of Commerce of Minneapolis, died Jan. 7, 1918, of pneumonia. Mr. Newhall was well known among the engineers of Minneapolis. He came from Chicago in 1909 to take the position he held until his death.

Personal

Prof. A. N. Talbot, of the University of Illinois, has been elected president of the American Society of Civil Engineers.

Guy E. Tripp, who was chairman of the board of directors of the Westinghouse Electric and Manufacturing Co., has been placed in charge of the Production Division of the Ordnance Department.

John D. Stout has been appointed Chicago representative for The Terry Steam Turbine Co. Mr. Stout was at one time assistant engineer of the company and was recently transferred from the New York office, where he was assistant manager.

Milton Rupert was recently elected vice president and assistant treasurer of the R. D. Nuttall Co., of Pittsburgh, Penn. He has been with the Nuttall Co. since March, 1893, holding various positions. In 1903 he was appointed head of the general offices. During the latter part of this period he was assistant to the president and general manager. In his new position Mr. Rupert will have charge of sales and manufacturing activities.

Engineering Affairs

American Institute of Steam Boiler Inspectors will hold its regular meeting Thursday evening, Jan. 31, in Engineering Societies Building, 29 West 39th St., New York City. The annual election of officers will take place and business in connection with the annual dinner will be taken up.

New Chapter of the A. A. E. Started in Philadelphia—The first meeting of the American Association of Engineers was held at the Bellevue-Stratford Hotel on Friday, Jan. 18. Frank P. Roth was elected chairman and a temporary club was formed with fifteen new members. A. H. Krom, general secretary of the organization, was principal speaker and he outlined the "National Association Plans." Discussion followed by T. J. Stone Edelen, Kern Dodge, Joseph B. Smith and Howard K. Hayes. The spirit of the meeting indiciated that Philadelphia will soon have a local office of the national business organization for engineers. The meeting was a close "second" to the one in New York City on the evening of Jan. 16.

Miscellaneous News

Boiler Explosion Wrecks Train — The night express train of the Rutland R.R., bound from Montreal to Boston, was wrecked near Middlebury, Vt., early Jan. 22, by an explosion in the locomotive. The fireman was killed and the engineer probably fatally hurt. Some of the cars of the train were derailed and several passengers received minor injuries.

A Boiler Explosion occurred at the sawmill of D. K. Walters at St. George, S. C., on the afternoon of Jan. 7, severely injuring three persons, including the owner and his son, the latter's condition being serious, and completely destroying the mill and machinery. Several negro workers were shaken up and mules and horses which were nearby were injured. The cause of the explosion is unknown.

A Boiler Explosion wrecked the plant of the municipal water-works at Swansea, Ill., on the night of Jan. 12, killing two men and seriously injuring two more. The plant, a story and a half brick building, was completely destroyed by fire, the village having no fire department. The cause of the explosion is unknown, but it is supposd it was because of low water in the boiler. The loss is estimated at $15,000.

A Boiler Head Blew Off in the heating system in the basement of the Chittenden Hotel, Columbus, Ohio, on Jan. 8, flooding the engine room with boiling water and steam, and injuring six men, one severely, who died later at the hospital. At the time of the explosion the men were busy removing coal from a pit near the end of the boiler to the fuel room, and when clouds of steam made it impossible for them to find their way out, they were forced to stand in the scalding water until firemen and police arrived to remove them in ambulances. The hotel manager stated that the system had been inspected and approved more than a month ago. A weak tube in the boiler was probably the cause of the accident, it was said.

Business Items

Orleans Cotton Mills, Inc., is the new name of the corporation formerly known as the Kohlman Cotton Mill and Manufacturing Co., New Orleans, La.

The Hydraulic Press Manufacturing Co now occupies its new buildings at Mount Gilead, Ohio, and the plant is again in operation to its full capacity. The new equipment is specially adapted for the building of hydraulic presses, pumps and valves.

Ford, Bacon & Davis, Engineers, announce the formation of the Ford, Bacon & Davis Corporation, organized for the purpose of conducting a general contracting business, with particular reference to industrial, public-utility and power plants, steam and street railroads, docks, steamship and railway-terminal facilities, subways, tunnels, hydro-electric and irrigation projects. In effect this means the continuance in corporate form of construction work which heretofore has been handled by the firm direct. The corporation's organization comprises men skilled and experienced in engineering and contracting work by the most modern and economical methods. It is provided with ample capital to insure the successful completion of any work which it may undertake, and starts business with important work already entrusted to it. Its headquarters are at 115 Broadway, New York, with offices at New Orleans and San Francisco. The facilities available to the new corporation from the firm of Ford, Bacon & Davis, now in its 24th year, which continues as heretofore, assure a continuance of this firm's standard of both engineering and construction efficiency and enable both design and construction to be carried on with a degree of coördination which should make for economy and rapidity of work.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Jan. 24, 1918	One Year Ago	Jan. 24, 1918	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Jan. 24, 1918	One Year Ago	Jan. 24, 1918	One Year Ago
Clearfields....	....	$3.00	....	$4.25—5.00
Cambrias and Somersets...	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Jan. 24, 1918	One Year Ago	Jan. 24, 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$7.00—7.25
Buckwheat ..	4.30—5.00	2.75	5.50—6.00	6.50—7.00
Rice	3.75—3.95	2.20	4.50—5.00	4.50—5.00
Barley	3.25—3.50	1.95	4.00—4.25	3.25—3.50
Boiler	3.50—3.75	2.20	....	....

Bituminous smithing coal, $4.50—5.25 f.o.b.

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)...........................	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide		Independent
	Jan. 24, 1918	One Year Ago		Jan. 24, 1918	One Year Ago
Buckwheat ...	$3.15–3.75	$2.00	$3.75	$2.90	$4.15

Black Creek, Cababa ...	2.40	2.65	2.15

Government figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

PROPOSED CONSTRUCTION

Ala., Geneva—The Geneva Power Manufacturing Co. has plans under consideration for the erection of a hydro-electric plant on Double Bridge Creek.

Ind., Ft. Wayne—The Board of Public Works plans to build extensions to the electric-lighting plant. Estimated cost, $25,000. F. M. Randall, City Engr.

Iowa, Independence—The State of Iowa plans to build a power house in connection with the State Hospital for Insane, including the installation of 1 generator and 2 boilers. H. T. Liebbe, State House, Des Moines, Arch.

Kan., Oakley—City plans to install new generating equipment in its electric lighting plant, including a 150 to 175-hp. engine and a new well and motor. G. Maurer & Son, Engr.

Ky., Jackson—The Jackson Light and Ice Co. plans to rebuild its power plant, which was destroyed by fire.

Minn., St. Cloud—The Pan Motor Co., care of G. Booth, is having plans prepared for a power house and a drop forge plant.

N. J., Kearny—The Federal Shipbuilding Co. plans to build a large power house to cost $60,000 and a boiler shop to cost $70,000 in connection with its new plant.

N. J., Toms River—The Toms River Electric Co. has been granted permission by the Board of Public Utility Commissioners to issue $15,000 bonds; the proceeds will be used for addition and improvements to its plant.

N. Y., Brooklyn—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard, Brooklyn, under Schedule No. 1664, 15,000 ft. single, stranded, rubber covered wire and interior communication plain cable.

N. C., Esmeralda—J. T. Patrick and associates plan to build a new hydro-electric plant here.

Ohio, Akron—The Goodyear Tire and Rubber Co., East Market St., plans to build a brick addition to its boiler house. Estimated cost, $100,000.

Okla., Aline—City is considering the installation of an electric-lighting plant. Burns & McDonnel, Inter-State Bldg., Kansas City, Mo., Engr.

Okla., Wewoka—City plans to install an electric-lighting plant.

Okla., Woodward—City voted to issue $20,000 bonds for the erection of an electric-lighting plant. Noted Dec. 25.

Penn., Clifton Heights—The Kent Manufacturing Co. is having plans prepared by F. E. Hahn, Engr., 1112 Chestnut St., Philadelphia, for the erection of 1-story, 40 x 67-ft. power plant. Estimated cost, $50,000

Penn., Norristown—The Counties Gas and Electric Co. plans to issue $300,000 bonds; the proceeds will be used for extensions and improvements to its system. H. H. Ganser, Gen. Mgr.

Penn., Williamsport—The Lycoming Edison Co. plans extensive improvements and additions to its plant during the coming year. About $250,000 will be appropriated for this work.

Tex., Burnet—The Southwestern Graphite Mining Co. plans to rebuild its power house which was destroyed by fire. Loss, $6000.

S. C., Lockhart—The Lockhart Power Co., a subsidiary of the Monarch Mills, Union, plans to build a hydro-electric power plant here. E. Nicholson, Union, Treas. of the mills.

S. D., Faith—City has plans under consideration for the installation of an electric-lighting plant.

Va., Dungannon—C. F. Hagan, Bristol, trustee of P. Hagan Estate, has plans under consideration for the erection of a hydro-electric power plant on the Clinch River near here.

Va., Glenlyn—The Appalachian Power Co., Bluefield, W. Va., is having plans prepared by Viele, Blackwell and Buck, Engrs., 49 Wall St., New York City, for the erection of a steam driven electric generating plant on New River, including the installation of new equipment. Estimated cost, $2,000,000. H. Markle, Bluefield, W. Va., Gen. Mgr.

Va., Petersburg—The Virginia Railway and Power Co. plans to build an electric transmission line from here to Suffolk. C. B. Buchanan, Gen. Mgr.

Wash., Puget Sound—(Bremerton P. O.)—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard, Puget Sound, under Schedule No. 1658, air pressure reducing valves, 56 gate valves, brass, high pressure, steam and water valves, and brass low pressure, steam and water valves; under Schedule No. 1663, 16,000 ft. single-conductor, lighting and power wire and 13,000 ft. 2 conductor, lighting and power wire.

W. Va., Hartland—The French Coal Co. is in the market for an electric hauling locomotive.

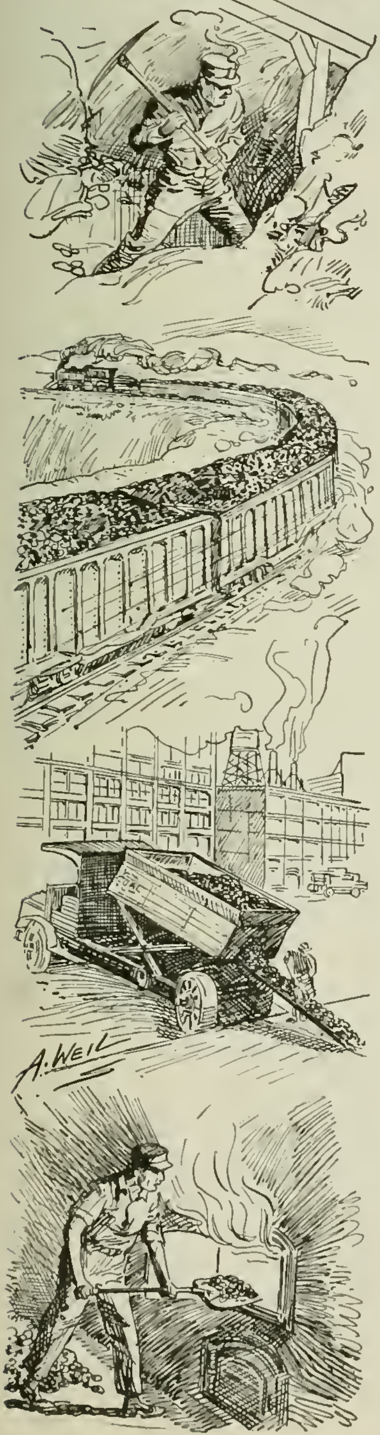
POWER

Vol. 47 NEW YORK, FEBRUARY 5, 1918 No. 6

The Greatest Ally

By

RUFUS T. STROHM



FROM crowded cities and scattered farms,
With sobered spirits and simple trust,
The thousands answer the call to arms
To humble tyranny in the dust;
But all their courage and all their strength
May yet come short of the final goal,
Since every effort depends at length
On Coal.

FOR every loyal and sturdy son
Must be accoutered from head to heel
In regimentals of drab and dun
With belt and rifle and blade of steel;
But looms and spindles are still and dead
And forge nor furnace can give its dole
Till boiler fires are gleaming red
With Coal.

WITHOUT its power by rail and sea,
The richest harvest of fruit and grain
Would waste and molder on bush and tree
And rot ungarnered on hill and plain;
While shot and shrapnel that burst afield
Would cease their thunder and crash and roll
If mine and stripping should curb their yield
Of Coal.

FOR coal unleashes the force of steam
That drives the engine and turns the shaft
And pricks the night with the blinding beam
That stabs and searches for hostile craft;
But cold and famine bestride the earth,
And want and suffering claim their toll,
When through disaster there comes a dearth
Of Coal.

LARGEST HIGH-HEAD FRANCIS TURBINE

By Arnold Pfau

The hydro-electric equipment installed in the White River plant of the Puget Sound Traction, Light and Power Co., near Sumner, Wash., is described. This plant contains two 18,000-hp. Francis turbines operating under a net head of 440 ft., which have developed over 44,000 hp. without any detriment to their efficiency. On account of the hydraulic conditions special engineering problems were involved, which have been solved by special features in design. A new 25,000-hp. unit is now being installed, which is the largest hydraulic turbine of this type in the world.

THE commercial results obtained from the electrified operation of the Rocky Mountain Division of the Chicago, Milwaukee and St. Paul Ry. have been so eminently satisfactory that it was decided to immediately proceed with the electrification of the Cascade Mountain division, which extends from Othello, east of the Columbia River, over the Cascades, to the end of the transcontinental line at Seattle and Tacoma. The western slope of the Cascade Mountain division will receive about 25,000 kw. of electrical energy from the Puget Sound Traction, Light and Power Co., at Seattle, Wash. This concern has a number of hydro-electric developments, the largest of which is the so-called White River plant near Sumner, Wash. The plant (see headpiece) with an initially rated output of 36,000 hp., developed by two hydro-electric units, designed and built by the Allis-Chalmers Manufacturing Co., was placed in commercial operation in November, 1911 (Stone & Webster, Engineers), and has since delivered power uninterruptedly and without requiring any repairs. It has been found that the turbines and generators can carry, without difficulty or detriment to their efficiency, a total load of 30,000 kw., or over 44,000 hp. on the shaft. Figs. 1 to 4 show a 25,000-hp. unit recently built, to be installed in this plant, which is the most powerful high-head Francis turbine in the world and is practically a duplicate of the two 18,000-hp. machines already in service.

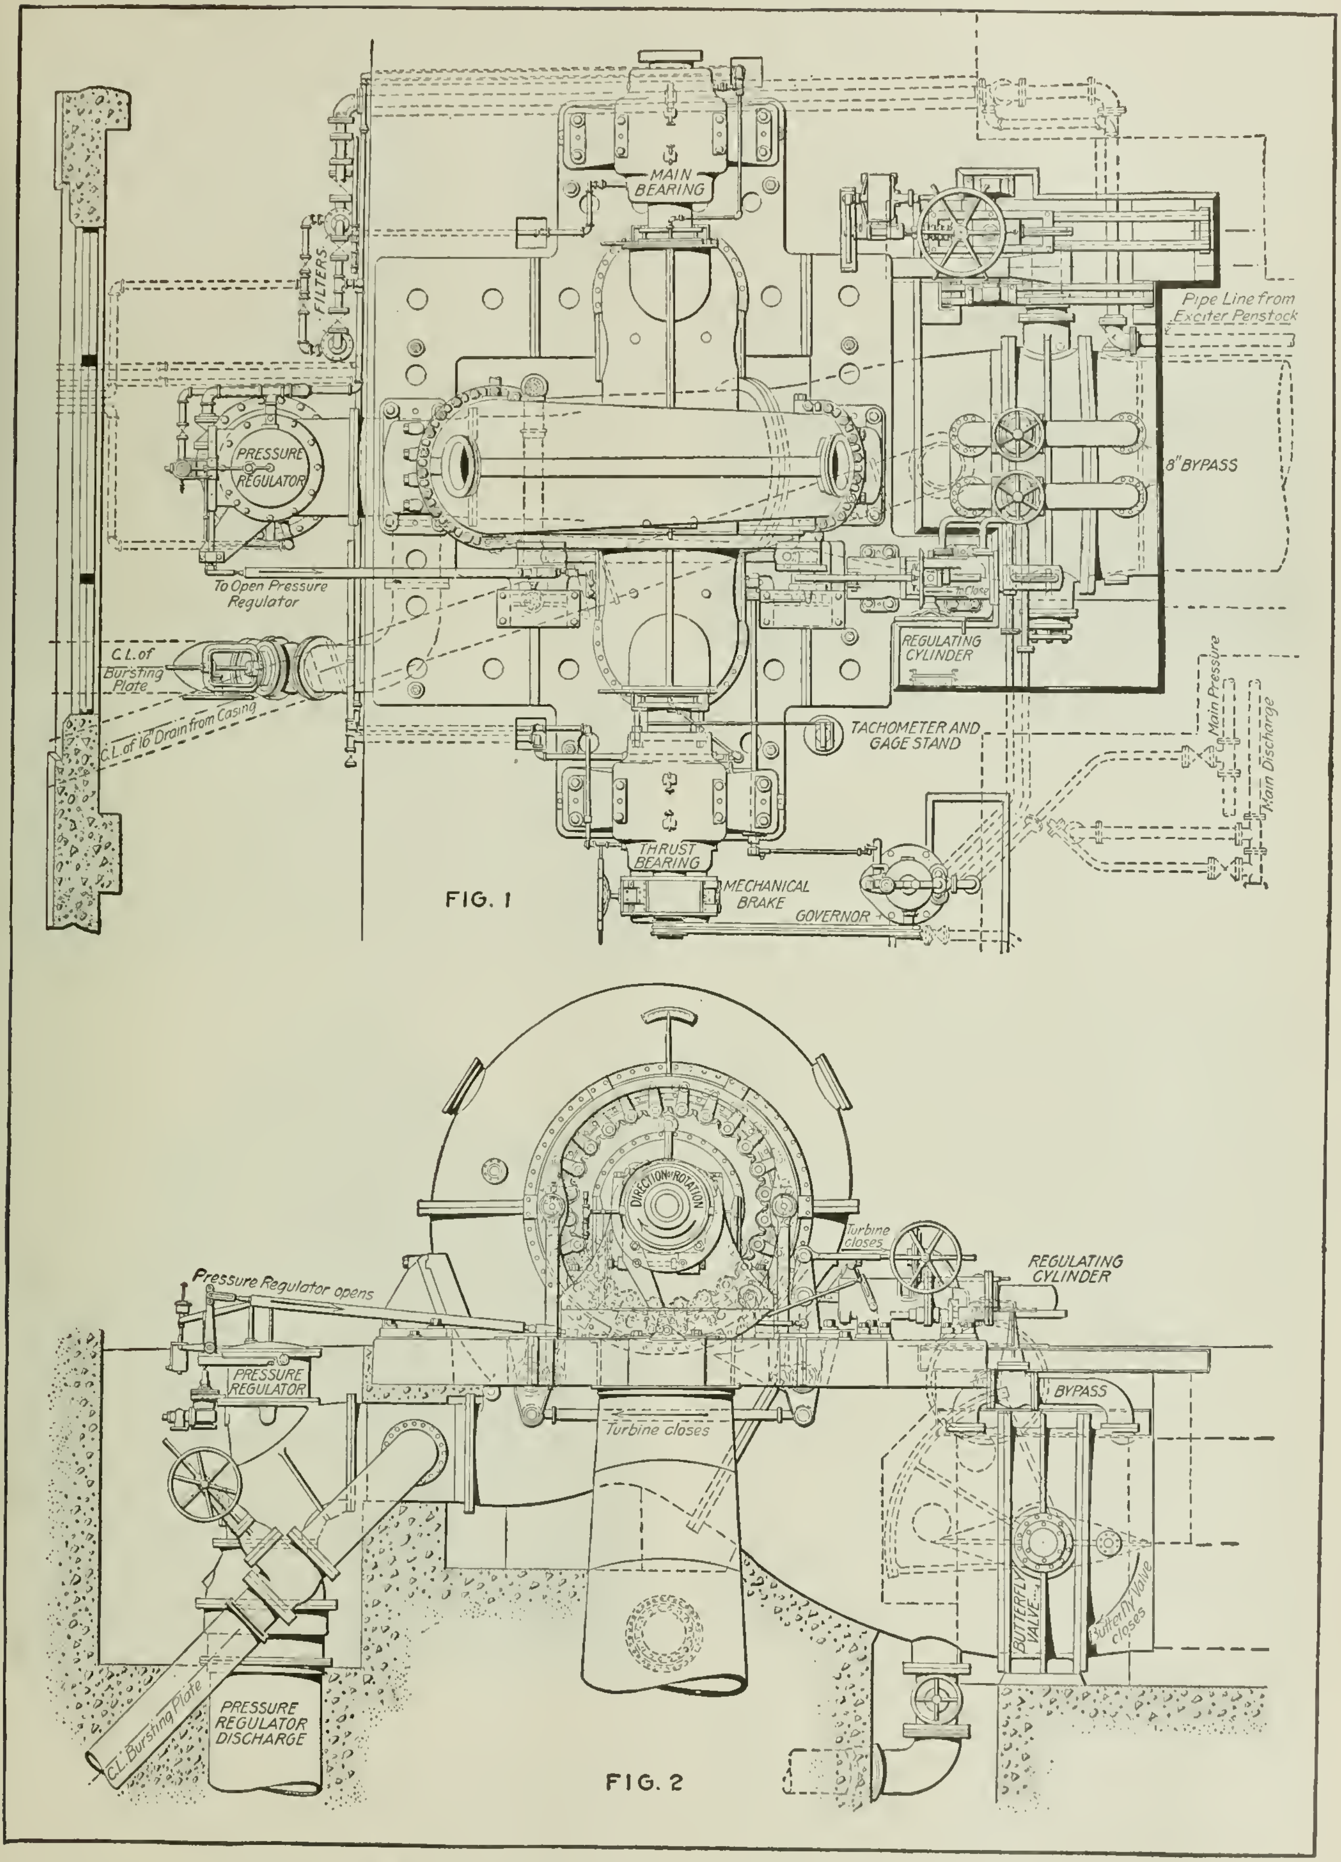
The plant has been laid out with a view of maintaining the highest economy of water, since it is combined with a large storage capacity, which serves to furnish the necessary operating water during dry seasons. The course of the White River, a typical mountain stream fed from one of the glaciers of Mount Rainier, is blocked by a timber-crib dam near Buckley, Wash., on one of the branches of the Northern Pacific's transcontinental line. The water is controlled by sturdy steel gates and led through a heavy timber flume into a forebay, which serves as a settling basin for the glacial silt, carried by the river at times in large quantities. Provision is made for draining and flushing this forebay to prevent its being filled up with deposits.

An open canal leads to the storage reservoir, called Lake Tapps, which was a small natural lake, now greatly enlarged by raising its water level about 35 ft., bringing its storage capacity up to 2,250,000,000 cu.ft., equivalent to 18,000,000 kw.-hr. obtained under the net head of 440 feet.

From Lake Tapps the water is carried through a deep open cut and a tunnel about 3000 ft. long and of sufficient area to carry 3000 cu.ft. of water per second. The tunnel ends in a forebay from which individual 8-ft. steel-pipe lines lead down to the power house.

In order to adhere to the principle of conservation of stored hydraulic energy of this plant, it was necessary to provide hydraulic equipment which is capable of controlling the bulk of the momentary variation of the commercial load of the Puget Sound Traction System. This variation is sometimes very severe, owing to rapid and large changes of the power required by the freight trains of the Puget Sound lines.

The long tunnel combined with the steel pipe lines, about 2500 ft. in length each, together with the requirement of a water-saving method of speed regulation under heavy fluctuations of load over a high-tension transmission line, offered a problem to the hydromechanical engineer, which required careful study and practical experience.



FIGS. 1 AND 2. PLAN AND ELEVATION OF 25,000-HP. FRANCIS TURBINE

In order to prevent excessive variations in speed and voltage of the power system, it was necessary to use a very sensitive governor and to quickly control the gates of the turbine. A sudden change in the flow of the water through the pipe lines and tunnel would cause pressure variations which would not only impair the regulation, but might accumulate to such an extent as to wreck the whole plant. A careful analysis of all the precautionary methods was made, and as a result it was decided to use:

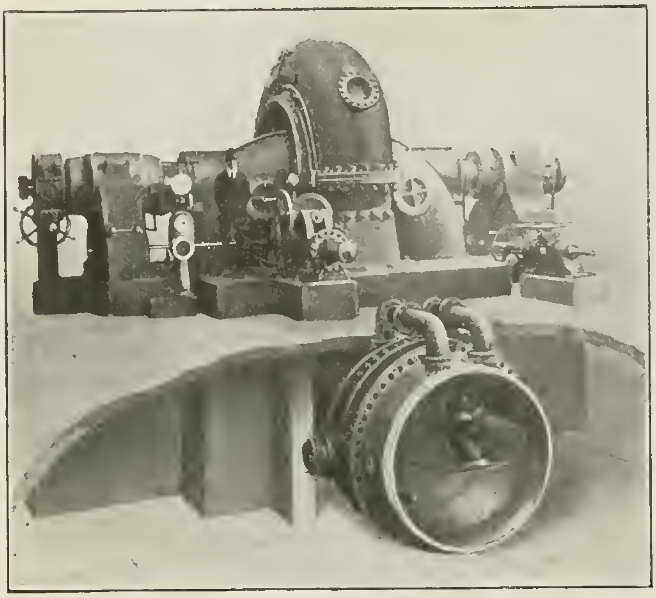


FIG. 3. COMPLETE TURBINE AND BUTTERFLY VALVE

1. A surge reservoir at the end of the tunnel for the purpose of preventing surges set up by the tunnel from materially affecting the pressure in the pipe lines and vice versa.
2. Pressure regulators so combined with the turbines that they permit of a sudden release of the water, otherwise brought to a stop when the governor closes the gates of the turbines quickly. In order to prevent excessive waste of water, these releases or bypasses slowly and automatically close at a rate so adjusted that the flow of water is gradually stopped without causing any appreciable secondary-pressure rises.
3. Air-cushion tanks, which supply hydraulic energy to the turbines when the demand of load is so sudden that the water cannot accelerate in the pipe line sufficiently fast to prevent a serious drop in pressure.

The proper combination of these devices, together with a fairly liberal flywheel effect of the revolving parts of the generators, made it possible to attain an accuracy in speed regulation which has been the subject of considerable comment in engineering circles.

The turbines of the initial installation are of the double-discharge, horizontal-shaft spiral-case type operating under a net head of 440 ft. at 360 r.p.m., similar to the unit shown in the figures.

The water from the penstock passes through a steel butterfly valve, shown in Figs. 1 and 2 and below the turbine in Fig. 3, of seven feet inside diameter, which, when closed by hand or electrically, is sufficiently tight to permit inspection of the interior of the turbine. The total normal pressure on the gate of this valve is about 1,000,000 lb. and it is far in excess of this when the valve is closed against the full penstock pressure in emergency cases. The water is brought to the runner through a steel casing of the scroll type, this being the most efficient method because the flow of water is steady and direct. Before reaching the runner, the water passes between a series of steel guide vanes or wicket gates, by means of which the quantity is quickly changed by the governor in accordance with the load to be carried by the generator.

The steel runner of the turbine is bolted to a flange forged solid with the turbine shaft and is of the double-discharge type, dividing the incoming water into two equal portions which discharge separately through a quarter turn and a tapered steel draft tube. The shaft revolves in two ring-oiling bearings with self-aligning ball-and-socket seats, one end having a solid flange for direct connection to the generator. The opposite end carries the mechanical hand brake (see headpiece and Figs. 1 and 3) for bringing the unit to a dead stop. The bearing near the brake serves also as a mechanical thrust bearing; the main thrust, however, is taken care of automatically by means of a simple and very efficient hydraulic balancing arrangement combined with the two runner rims and the adjacent portions of the stationary cover plates.

The spiral casing, quarter turns, bearings and brake are bolted to a heavy cast-iron bedplate, grouted into the foundation. The guide vanes are held in three bearings and are operated from a concentric steel shifting ring located outside of the casing. Two steel rods connect the shifting ring to bell-crank levers which in turn are actuated by a regulating piston guided by a crosshead. The oil pressure acting on both sides of the regulating piston is controlled by a double-acting, hydraulically balanced regulating valve bolted to the separate governor stand, Fig. 5, containing the flyballs and the relay of the governing device. The oil pressure is obtained from a central oil-pressure system located in the basement of the plant. It is produced

FIG. 4. COMPLETE TURBINE AND PRESSURE REGULATOR

in pumps of the rotary-gear type driven by electric motors or by a small waterwheel operated from the penstock pressure. The governor has a capacity of about 50,000 ft.-lb. and is capable of moving the turbine gates over their full stroke in one second.

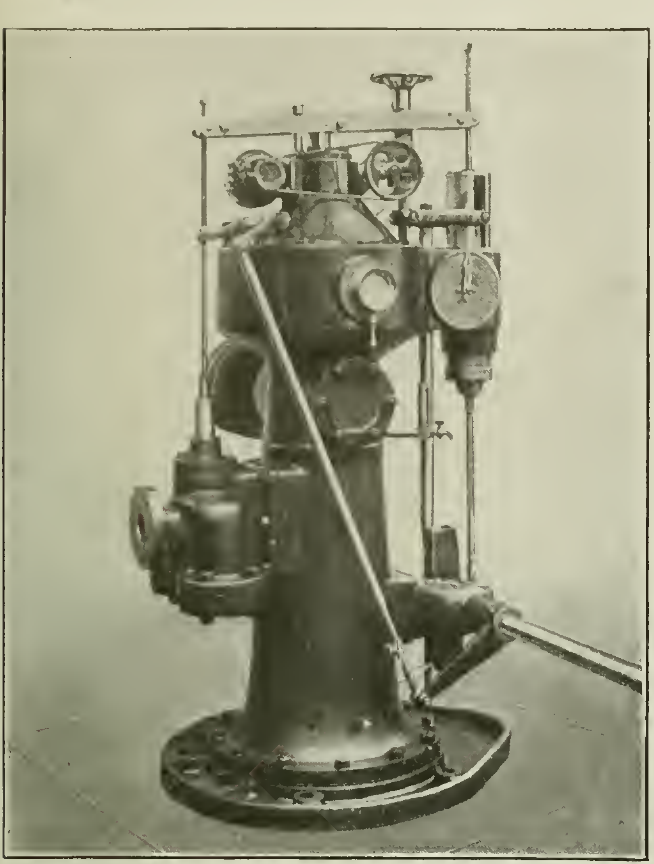

FIG. 5. GOVERNOR ACTUATOR FOR 25,000-HP. TURBINE

A pressure regulator (see Figs. 1, 2 and 4) is directly connected to a branch pipe provided on the lower portion of the spiral casing. It consists of an elbow with a circular disk valve, opening and discharging water downwardly through a plate-steel pipe into the tailrace. This disk valve is connected to a piston subjected to water pressure controlled by a regulating valve, which in turn is relay-operated from a direct connection to the turbine gates. An oil dashpot is so inserted into this connection that the motion of the turbine gates is transmitted to the regulating valve only when the governor closes the former quickly, a slow motion only being completely absorbed in the dashpot. Thus the discharge of the turbine can be quickly switched over from the turbine to the pressure regulator, and is there reduced slowly in accordance with the setting of the bypass in the oil dashpot, determining the rate of the closing motion.

The turbine discharges about 450 cu.ft. of water per second, and when the flow is stopped through the turbine gates in 1.5 sec., it will discharge through the pressure regulator to its full amount by the time the governor has closed the turbine gates. Thus the velocity of the water in the pipe line is not changed abruptly and no serious pressure rises occur.

After the units were placed in commercial operation, elaborate efficiency and regulation tests were carried out by the owner. It was found that the efficiency exceeded 90 per cent. and was still above 80 per cent. at about one-fifth load.

The full load of 20,000 hp. was thrown off suddenly, causing the governor to close the gates quickly. The speed did not rise more than 12 per cent. above normal, and the maximum pressure rise in the pipe line above normal did not exceed 5.5 per cent. as against a guaranteed pressure rise of 15 per cent. and a speed rise of 18 per cent.

After five years of continuous service one of these turbines was opened up for careful examination. The parts subject to hydraulic and mechanical wear were measured up and photographs taken in order to establish their durability. The unit was taken out of service Saturday evening and was delivering its regular power again after midnight, Sunday. No repairs whatever were considered necessary, and it was estimated that it would be good for another five years of continuous service under similar conditions.

The results of this examination were so gratifying that it was decided to build the new third unit, practically a duplicate of the first two. The results obtained as regards efficiency and speed regulation encouraged the purchaser to increase the rated horsepower from 18,000 of the original contract to 24,000 without increasing any parts except those directly affected, such as the runner, shafts, guide vanes, etc. It is expected that 25,000 hp. will be delivered to the generator shaft and that both the efficiency and the speed regulation will be at least as good as they are with the first units.

Conserving Waste Heat

Economists are continually calling attention to the necessity for intensified conservation of resources and greater efficiency in our methods of development. As respects the conservation of heat, it is doubtful if the manufacturers of reciprocating steam engines are giving that study to the saving of the heat of exhaust steam which their interest demands. The practicable savings through higher pressures, increased expansion, superheat, improved vacuum, reduced cylinder condensation and radiation are fairly well realized, but all these are nothing as compared with the potential conservation of the heat of exhaust. Here is presented to the engineer an extended field for endeavor. Where this heat is available for heating or mechanical purposes, the thermal efficiency of the reciprocating engine is vastly beyond that of the Diesel or any internal-combustion engine. Power then becomes a byproduct and the use of any other heat engine is prohibited. By persistent exploitation of this field a new lease of life for the languishing engine trade is possible. It devolves upon the steam engineer to extend the application of waste heat. He should consolidate the diversified industries in such a way that the manufacturer requiring power will take his modicum of heat from the steam and pass the remainder on to his neighbor, for use in mechanical or other processes. At the present time, we utilize, on an average, only 5 per cent. of the heat value of coal. The combustion engineer is rapidly whipping the boiler end of the steam plant into shape; an exhaust engineer is now in demand to coin into money the waste at the exhaust end—*Steam.*

While the Idle Millions Shiver

An exposition of the deplorable conditions at the great coal terminal at Perth Amboy, N. J., from which coal for New York and lower New England is shipped by water after arrival at the terminal by rail.

WALK slowly along the east side of Ninth Avenue between 34th and 35th Streets any day from daylight until after darkness falls and you will see a line of shivering wretchedness.

It is a coal line. It is a full block long and three persons wide. You find there aged women, rheumatic old men, sturdy workmen, young women, young men and belligerent yet laughing children. Each has a bag or a box, a wash boiler, baby carriage, trunk—anything to hold the treasure coal that is portioned out to each while three policemen preserve order. Be there snow, or rain or wind and biting cold, the shivering line is there.

Imagine standing in that line for hours, waiting, waiting, eagerly, hopefully watching for the coming of a two-ton wagon only to see it come in—empty! That happens.

This line is but one of hundreds in that city of six million souls, and it is truly indicative of the cruel suffering throughout the whole of the greater city and the country.

That line has nothing to do with power. But the industries, the buildings, the schools and hospitals are waiting in line just as are these stamping, crying people. And this not only in New York, but from the Atlantic to the Pacific.

This is written on the day following the collapse of industry and commerce at the order of the Fuel Administrator. We are not arguing the expediency of that order, for we believe that as a measure to relieve rail and terminal congestion it is warranted. It cannot have been issued to conserve fuel because for this purpose it is too obviously doomed to failure even for contemplation.

Having seen the woeful coal lines and experienced the shock of the Garfield order, let us see the conditions at the great coal-distribution center that supplies Greater New York and lower New England, as seen by two *Power* representatives on the day the Garfield order went into effect. These are anthracite-consuming sections for the most part. The distribution centers are Perth Amboy and South Amboy, on the New Jersey coast, the former handling hard coal, the latter soft coal almost exclusively. The coal comes from Pennsylvania to the water front by rail and is there transferred to barges which take it to the New York and New England waterfronts. It is not more than twenty miles from Manhattan Island to Perth Amboy—a short tow.

The waterways from the coal-unloading piers have been seriously obstructed with ice; but at the time of our visit they were free. At the docks near the unloading piers was one group of 55 empty barges, averaging 850 tons each. Farther to the left were other groups of a few barges each. Some had just come in, but the greater number had been there many days. To make the irony of the situation most stinging, the "Hurry Up," of New York, had been there 27 days up to Jan. 18, the day of our visit. Demurrage of 5 cents per day per ton capacity is what the coal consumer must pay—is what those wretches in the coal line must pay. The capacity of the "Hurry Up" is about five hundred tons. Twenty-seven days' demurrage means that the consumer of the coal she gets must pay $1.35 per ton, not for coal, but for demurrage. Fig. 2 shows some empty barges.

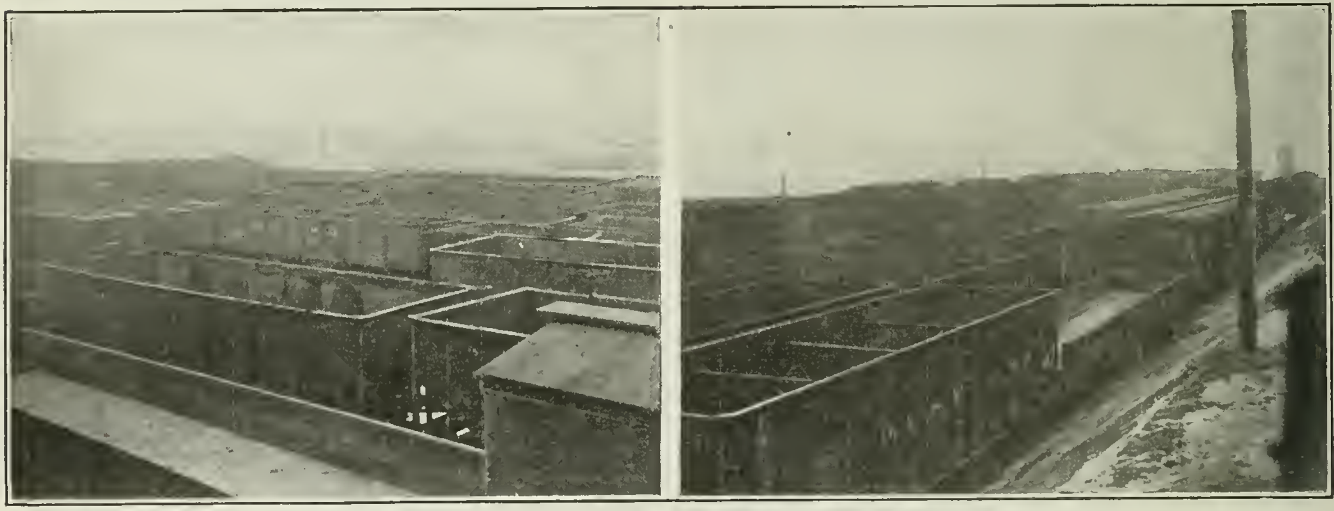

FIG. 1. VIEW OF EMPTY CARS, LOOKING EAST AND WEST, PERTH AMBOY, N. J.

And this while thousands and thousands of tons of coal stand in cars at the unloading piers not a thousand feet away, and while well above 300,000 tons lie farther back along the rails waiting to come in. (See Fig. 1.)

It is to weep!

At Perth Amboy there are two unloading piers where coal is dumped from the cars to the barges. One pier has a machine unloader which lifts and dumps one carload at a time. At the other or large pier the cars are unloaded by hand. There are thirty chuteways down which the coal may run to the barges below. On the day of our visit three were being used—the pier working at one-tenth full capacity. True, a few chutes are missing from the chuteways; but their absence only adds to the neglect so strikingly, so astoundingly, manifest.

Six men per car is the crew used in unloading the frozen coal. Twenty-six men were all that were working on that pier unloading on Jan. 18. There should have been six times as many.

The coal is frozen solid in the cars, and the finer the coal the more solid the frozen mass. Back at the entrance end of the pier are 114 steam thawing heads, all piped, valved and ready for use. Four were in use during the time of our visit. Two cars had one steam lance each stuck into the middle of the coal, and one car was using two lances. It is easily possible to so place cars that four lances per car may be used.

Frozen coal is the most serious cause of the delay in unloading and of the congestion which, remember, affects not only those local yards, but the whole line back to the very mines, where lack of cars to reecive their coal is causing miners to walk the streets even while this is written. And this while the shivering coal lines wait and weep; while industry dumps its fires and the victims of enforced idleness shiver and, in many instances, lose the wages with which they hoped to buy coal.

FIG. 2. A FEW OF THE MANY EMPTY BARGES

But this is not the worst. The writer got into a car of culm on the pier, which the crew, gone to lunch, were unloading. He picked at it with pickax and bar. It was as hard as concrete. Six men have been allowed to spend two full days unloading a car of culm! They were unloading it while we were there. Think of it. Six men two days unloading one car of culm while that shivering line pleads for the nut and stove and pea and egg that lies by the thousands of tons right at this very pier. Fig. 3 shows the little ice in the bay.

No attempt seems to be made to sidetrack the frozen culm until the other grades which, though equally frozen, may, because of the larger particles, be unloaded ten, aye, fifty times as fast. And then there is the relative heating value. Fig. 4 shows frozen culm.

As things are managed now, a dealer must have his barges on the spot or he can get no coal. If one or a hundred cars of his coal come into the yards and his barges are not there, the coal remains in the cars until *his* barges arrive.

They work nine or ten hours a day on this pier, and if it is worked at over one-tenth its capacity there were no evidences of it when we were there. Why has not someone provided for 24-hour day operation?

FIG. 3. THE ICE IN THE BAY IS NEGLIGIBLE

The machine-unloading pier works very slowly owing to the coal being frozen.

At South Amboy, the soft-coal terminal, there is every evidence of adequate and proper equipment, of organization, directive intelligence and adequate labor. There are three thawing sheds, while at Perth Amboy there is no thawing shed.

One who knows something of the bitter suffering, of the idleness, of the loss of production and the general serious disturbance of the whole social, economic and industrial fabric, wonders if the conditions described in the foregoing are general. He cannot but seek a motive for it all. It is preposterous to say that the conditions at Perth Amboy simply happen.

The Fuel Administration may know the answer. The public rightly assumes that it does, and it rightly expects it to lose no time in correcting such conditions.

Through it all one thought frequently creeps into the fore of the writer's mind: Some of the public utilities tried hard to get coal, to keep going. They pleaded, demanded and finally precipitated a crisis by turning off the lights and stopping the industries. Then came action. If that shivering line, that line of humans and of buildings, hospitals and industries discover too many Perth Amboys, how long before it will precipitate a crisis as only the constituents of such a line can precipitate it?

It is worth pondering over, Dr. Garfield.

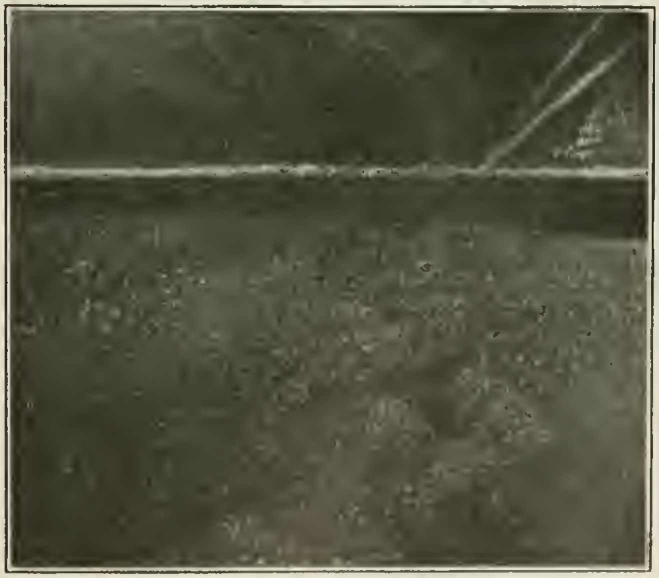

FIG. 4 CULM FROZEN AS HARD AS CONCRETE

Alternating-Current Automatic Starters for Squirrel-Cage Induction Motors

By W. H. PATTERSON
Manager Resale Section, Industrial Department, Westinghouse Electric and Manufacturing Company

An explanation of the operation of an automatic alternating-current starter for squirrel-cage type induction motors. Some of its applications and limitations are pointed out.

ALTERNATING-CURRENT automatic starters are now quite commonly used for squirrel-cage induction motors, especially where it is desired to start the motor from a remote point, such as a motor driving a centrifugal pump, an air compressor, a fan or a blower.

One type of these starters, built by the Westinghouse Electric and Manufacturing Co., consists of a slate panel, Fig. 1, upon which are mounted two alternating-current contact switches—one two-pole switch *R* and one four-pole switch *S*. Both these switches are equipped with magnetic blowouts for quickly destroying the arc when opening the switch. An accelerating relay *H*, a transfer relay *T* and a no-voltage protection relay *P* are also mounted on the panel. Either fuses or overload relays are mounted on the panel to protect the motors from overload. In Fig. 1 fuses *F* are shown on the front of the panel, and in the wiring diagram, Fig. 2, two overload relays *O* and O_1 are used. An auto-transformer is mounted on the rear of the panel. Fig. 2 shows a complete wiring diagram of the controller for starting a two-phase motor. With the line switch closed and all contactors on the controller in their normal position, all circuits through the controller and to the motor are open. The different steps in the operation of the controller are explained as follows:

Closing the start push-button, as in Fig. 3, establishes a circuit through the operating coil of the no-voltage protection relay *P*. This circuit is established from L_1 of the supply circuit through the contact on overload relay *O*, down to 9 on the no-voltage protection relay *P*, through this coil up to the contact on the overload relay O_1, then down to the start push-button to the stop push-button, which is normally closed, back to L_3 terminal on the control board, and to the other side of the supply circuit L_3 on the line switch, as indicated by the arrowhead. This energizes the coil on the no-voltage protection relay *P* and causes it to close its contact *L* and the auxiliary contact 11-12 at the bottom of the relay, as in Fig. 4. Closing contact 11-12 establishes a holding circuit for the relay coil *P*. This circuit is the same as in Fig. 3 excepting, instead of the current passing from terminal 11 on the controller down to the starting button, it goes through the auxiliary contact 11-12 on relay *P* and to terminal 12 on the stop button, through this button back to L_3 terminal on the line switch, as indicated. This shunts out the starting button; therefore it can be released and allowed to take its normally open position, without in any way interfering with the operation of the controller.

The closing of the no-voltage protection-relay contact *L* also establishes a circuit through the operating coil *X* of the four-contactor switch *S*. This circuit is made from L_1 of the supply circuit, through the contact of the no-voltage protection relay, to terminal 6 on coil *X*, through this coil and up to point 1 on the transfer relay *T*, then to point L_3 on the transfer relay, which is directly connected to L_3 on the supply circuit, as shown by the arrowheads. Energizing coil *X* causes it to close the four-contactor switch *S*, as in Fig. 5. With the contactors in this position the motor is connected to the low-voltage taps of the auto-transformer.

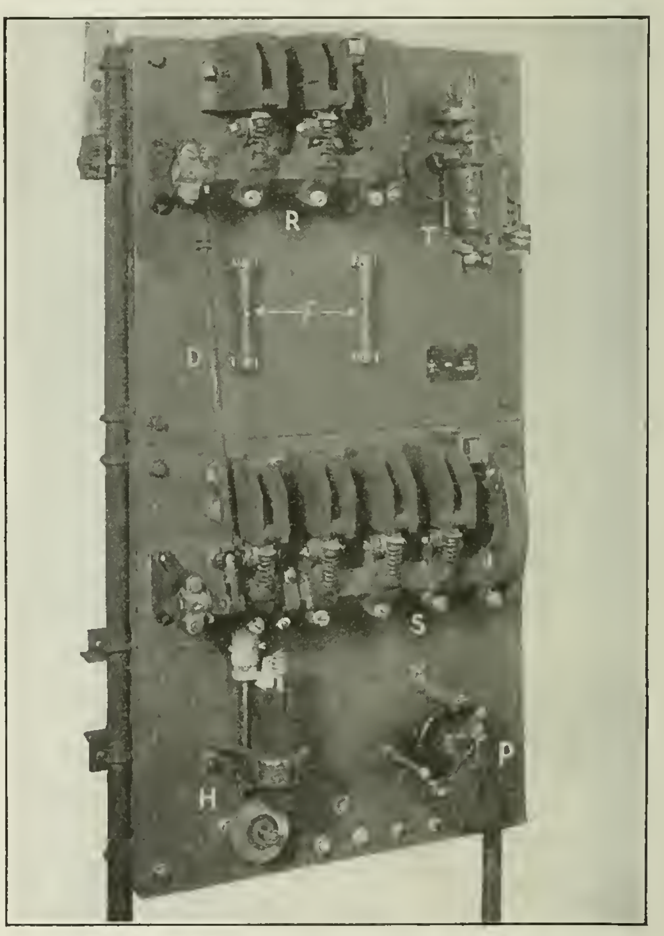

FIG. 1. AUTOMATIC STARTER FOR SQUIRREL-CAGE TYPE INDUCTION MOTOR

Contactor *A* on the four-pole switch is connected to terminal A_3 at the center of one leg of the auto-transformer. This connection gives 65 per cent. normal voltage at the motor terminals at starting. Connecting terminal *A* on the switch to A_4 or the auto-transformer will give a higher voltage, while connecting to A_2 will give a lower starting voltage at the motor terminal.

The circuit to the *A* leg of the auto-transformer is from L_1 on the line switch down to L_1 contactor on the four-pole switch *S*; from here to terminal A_0 on the auto-transformer through the transformer to A_3, then to the accelerating relay coil *H* to contact *A* on switch *S* and down to the *A* terminal on the motor; through one phase of the stator winding to A_1 terminal and up to L_3 terminal on the controller to the L_3 pole of the line switch. Current flowing through section A_5-A_3 of the auto-starter induces an opposing voltage in section A_3-A_1. This opposing voltage causes a secondary current to flow from A_3 through the motor as did the primary current, but instead of passing from L_3 terminal on the controller to the line switch, this current takes the path from L_3 to A_1 on the auto-transformer, thus completing the secondary circuit as indicated by the arrowheads. The circuits for the *B* phase may be traced out in the same way and are indicated by arrowheads. Accelerating relay *H* is adjusted so that the inrush current when the motor is first connected to the line holds contact 2-L_3 open, but as the motor increases in speed and the current through coil *H* decreases, its strength decreases to a point where the contactor is allowed to drop and establish a circuit between points 2 and L_3. This completes the circuit for the transfer-relay coil *T*.

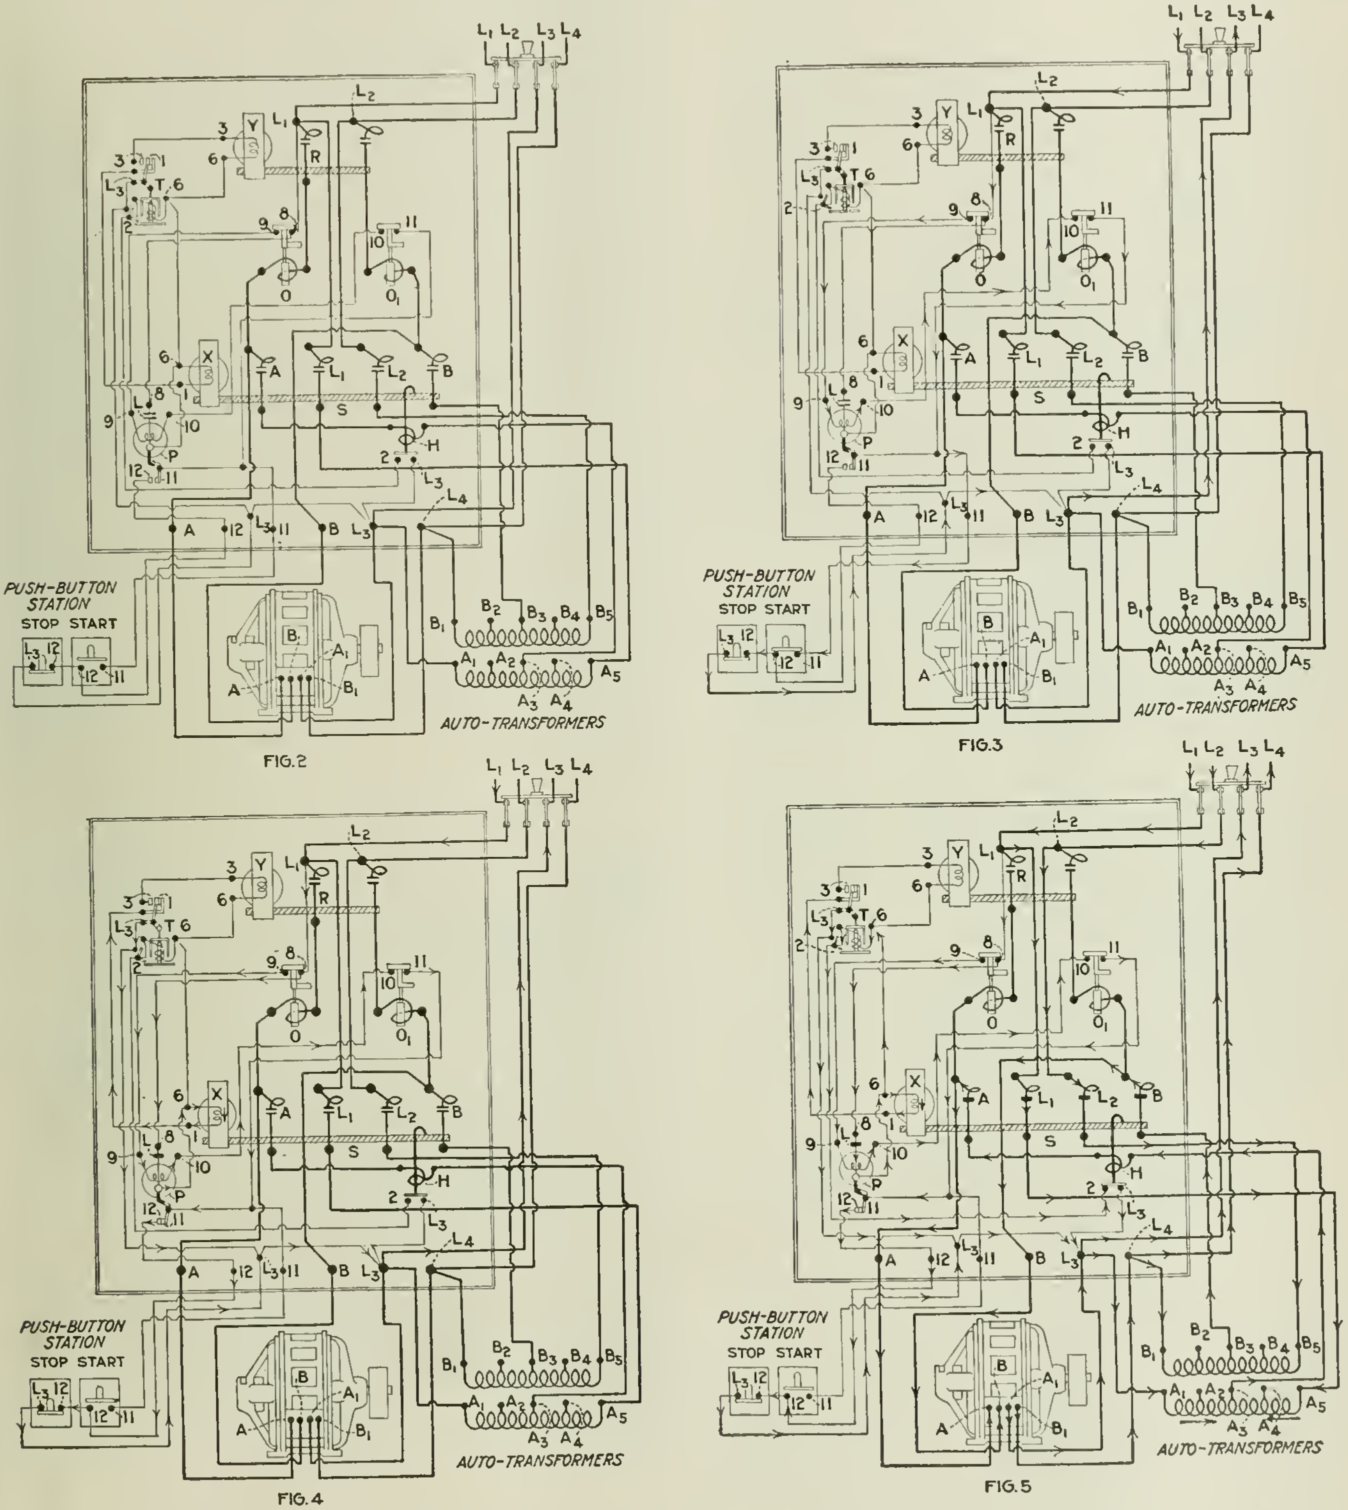

FIG.2 FIG.3 FIG.4 FIG.5

FIGS. 2 TO 5. WIRING DIAGRAMS OF CONNECTIONS FOR THE CONTROLLER, FIG. 1, IN DIFFERENT STAGES OF STARTING A TWO-PHASE, SQUIRREL-CAGE TYPE MOTOR

The circuit for relay coil *T* is from terminal 6 on the coil *X*, through the coil on relay *T* to terminal 2 on the relay down to 2 on relay *H*, to the L_3 terminal of the line switch. The operating coil on the transfer relay *T* being energized, draws up its core and makes contact at point 2 at the bottom and opens contact 1 at the top, and closes contact 3, as shown in Fig. 6. Closing point 2 creates a direct circuit for the transfer-relay coil from 6 on coil *X* to 6 on the transfer-relay coil, to contact 2 up through the core to terminal L_3 and down around to the L_3 terminal on the line switch. This establishes a holding circuit for the transfer-relay coil and shunts out relay contacts 2-L_3 on relay *H*, so that their opening when the four-pole contactor switch *S* opens will not interfere with the operation of the transfer relay.

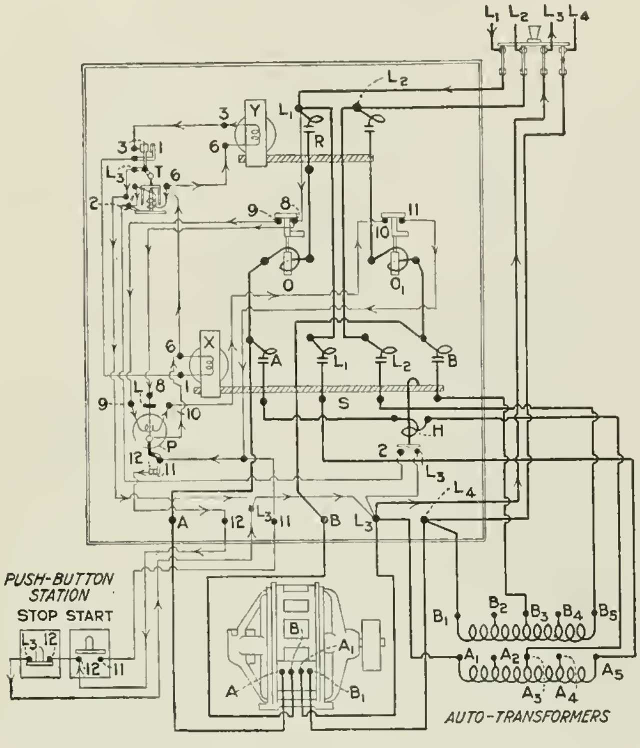

FIG. 6

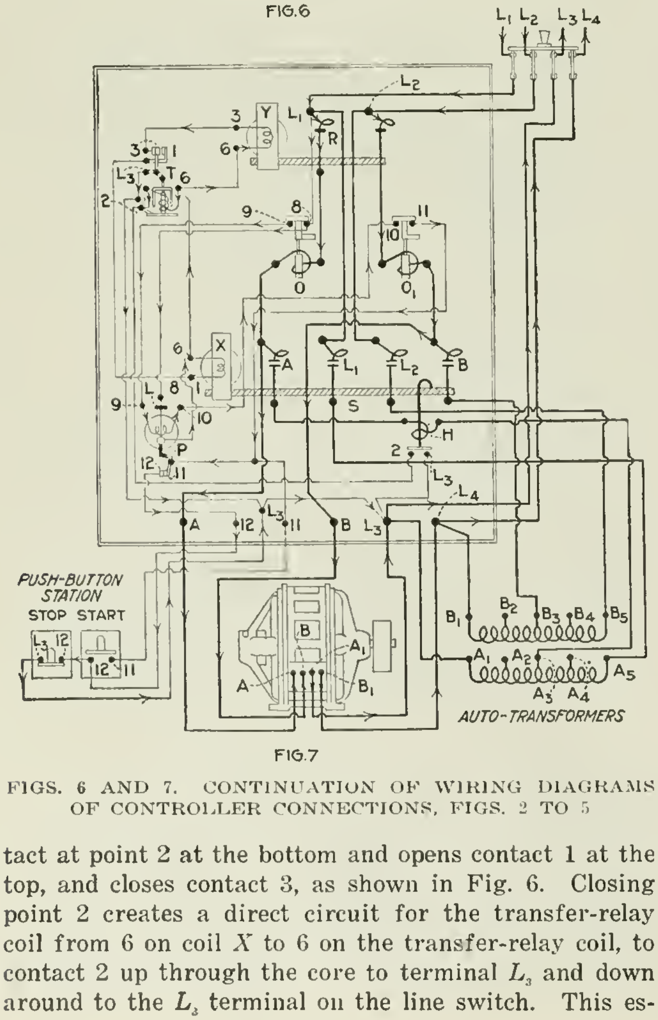

FIG. 7

FIGS. 6 AND 7. CONTINUATION OF WIRING DIAGRAMS OF CONTROLLER CONNECTIONS, FIGS. 2 TO 5

Opening contact 1 on the transfer relay interrupts the circuit of coil *X* on switch *S* and allows the switch to fall open, as shown in Fig. 6. The closure of contact 3 on the transfer relay *T* establishes the circuit for the operating coil *Y* on the two-pole switch *R*. This circuit is from terminal 6 on the transfer-relay coil over through coil *Y* around to terminal L_3 on the transfer relay, and to the L_3 terminal of the line switch. This circuit causes the two-pole contactor switch *R* to close, as in Fig. 7, and connects the motor directly to the line. The circuit through the motor is from L_1 on the line switch down through *A* phase of the motor and back to L_3 on the line switch, and from L_2 down through the *B* phase of the stator winding back to L_4 on the line switch, as indicated by the arrowheads.

Since the circuit of the transfer-relay coil *T* and operating coil of the two-pole contactor switch *R* passes through the no-voltage relay *P* it will be seen that the opening of the no-voltage protection relay *P* will break the circuit, allowing the two-pole contactor switch and the transfer relay to open and remain open as in Fig. 2, until the start button is again pressed.

The pressing of the push-button marked stop breaks the circuit through the no-voltage protection-relay coil, allowing this relay to open, thus breaking the coil circuit of transfer relay *T* and switch *R*, allowing the latter to open and stop the motor. It will also be seen that the operation of either of the overload relays *O* and O_1 will open the circuit that holds the no-voltage protection relay closed, thus opening the circuit through the coil of the main two-pole switch *R*.

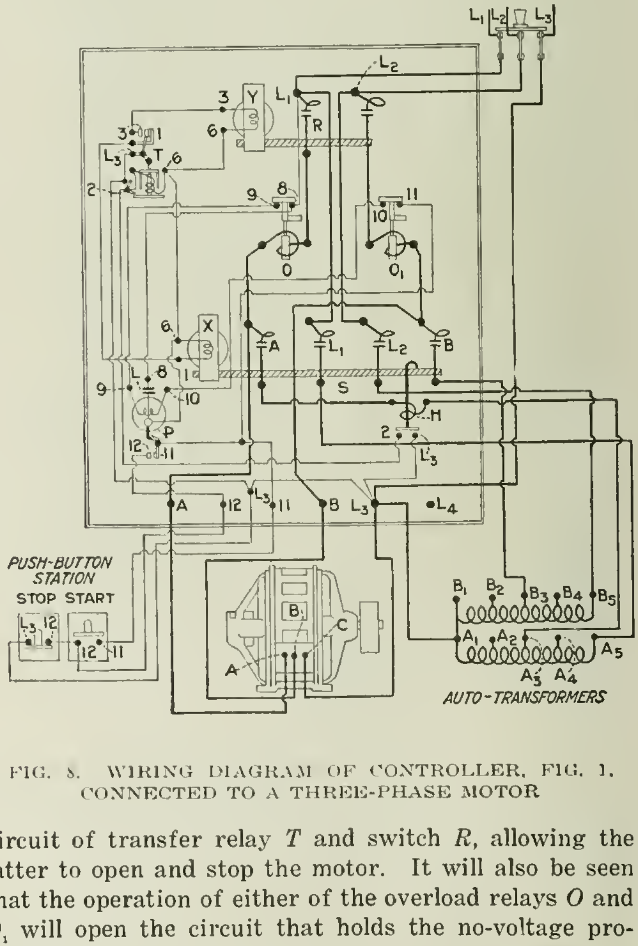

FIG. 8. WIRING DIAGRAM OF CONTROLLER, FIG. 1, CONNECTED TO A THREE-PHASE MOTOR

In general, the operation of the automatic autostarter is the same for either two- or three-phase motors, Fig. 8 shows the connection for a three-phase motor. The principal difference is in the connections; in the case of the three-phase panel line L_3 is used to replace the line marked L_3 and L_4 in the two-phase diagram.

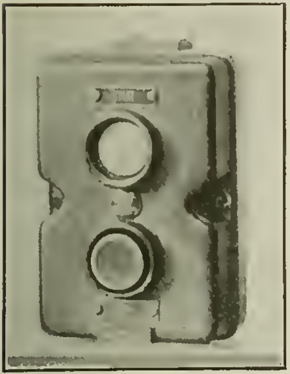

FIG. 9. PUSH-BUTTON STATION

The two contactor switches are mechanically interlocked by the rod *D*, Fig. 1, so that it is impossible for both switches to be closed at the same time. With one type of this controller without the no-voltage protection relay *P*, in case of failure of voltage, the switches automatically open and upon return of the voltage will automatically close again in their proper sequence. This is termed "no-voltage release," and it is satisfactory to use a controller of this kind with a motor driving a centrifugal pump, air compressor, fan or blower. However, on a motor driving a machine tool or a woodworking machine, where unexpected starting up of the tool would render possible injury to the workmen, the controller is equipped with the additional relay *P*, shown in the lower right-hand corner of the panel, Fig. 1, which prevents the switches from closing upon return of power until the master switch or a push-button station is again closed. A controller equipped with this relay is termed as having no-voltage protection.

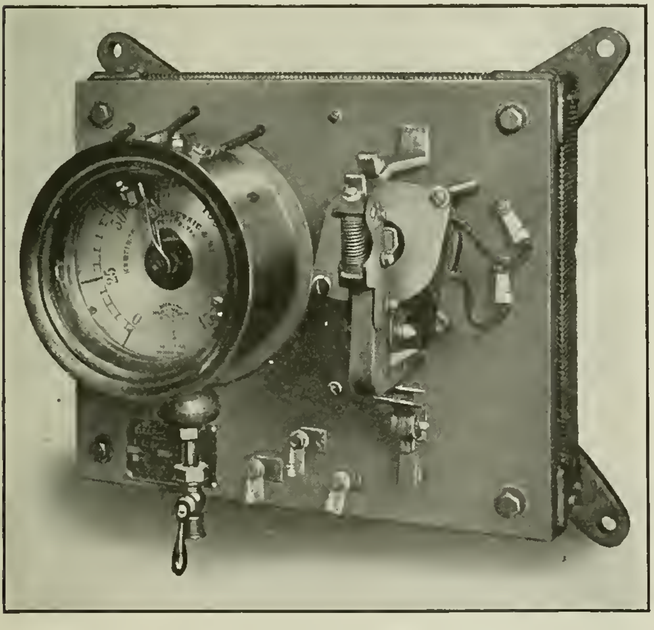

FIG. 10. PRESSURE-GAGE MASTER SWITCH

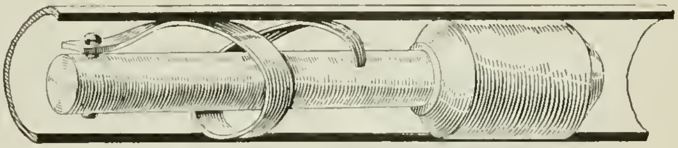
These controllers may be operated by hand by "start" and "stop" push-buttons, Fig. 9, or automatically by a float-type switch or a pressure-type master switch, Fig. 10. The float-type switch is used in liquid tanks, and the motor is started when the level falls to a certain point and is again automatically stopped at the desired upper level. The pressure-gage master switch is used with a motor driving a compressor or pump emptying into a closed pressure system. The switch makes the connection to start the motor when the pressure falls to a predetermined point and stops it when the desired pressure is reached.

Griffin Condenser-Tube Cleaner

Cleaning condenser tubes is not agreeable work, and with many of the methods employed, considerable time and labor are spent in cleaning them. Several devices for doing this work have recently been described in *Power*. The latest one that comes to our attention is illustrated herewith, and it has been devised by C. M. Griffin, 114 Spruce St., Newburgh, N. Y.



CLEANER IN CONDENSER TUBE

The tool is designed to clean condenser tubes by being forced through them by water pressure of about 100 lb. per sq.in. Its scraper blade is loosely attached to the front end of a central bar, and is tempered and ground to fit the tube, the size depending upon the tension desired. The head or piston at the rear end of the bar is made about 0.04 in. smaller than the tube. The scraper is made with clearance and rake, and retains a sharp edge while being used. Each tool will clean 1000 or more tubes before it is worn out. It is not necessary to provide protection for the tool while being used, and it may be shot against the head of the condenser and dropped to the bottom of the water box without damage.

Although it is not intended that the tool shall revolve by going through the tube, it does make three or four revolutions in passing through an 18-ft. tube, which requires about 3 sec. time, and with 20 or 30 tools at work, two men can clean about 200 condenser tubes per hour.

Automatic Damper Regulation

By C. A. Morris

We may put a force in motion and with a fixed degree of control operate it within a given range and with maximum efficiency, but if the use of this force is not required at the maximum all the time, yet still must be held in readiness to meet any demand within the range governed, then I believe it is necessary to have some method of automatic regulation in order that maximum efficiency may be maintained. If the mind and hand of man through the medium of the eye are depended upon for proper regulation, it is better than no regulation, but a mechanism that will act automatically and at a point not discernible to human senses, it seems to me, will be more efficient and less exacting on the attention of the men in charge of the actual operation of the equipment.

When boilers are operating at a high point of rating against a load that is constantly swinging, frequently as much as 80 per cent., the judgment and action of the human element are inadequate to obtain the highest efficiency, and in this day of conservation we should put the accent on efficiency—not alone for pecuniary benefit to ourselves, but to help in a national crisis.

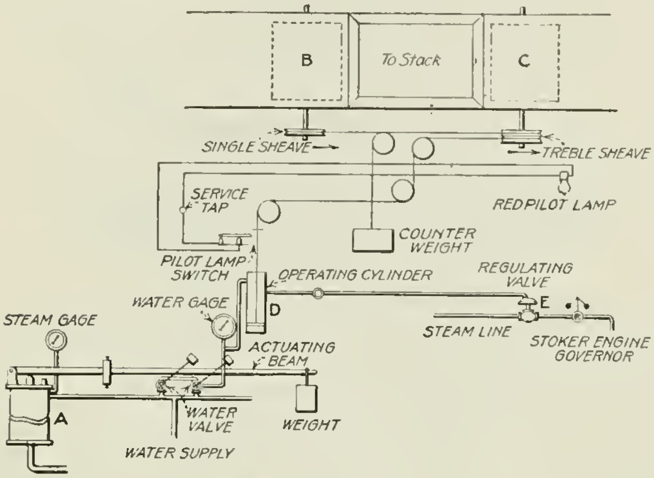


DIAGRAM OF DAMPER CONTROL

We have a station rated at 10,000 kw. with 4000 hp. in normal rating of boilers. The boilers are the Stirling type, eight in number. Two are in disuse owing to the fact that they are equipped with a type of stoker that is not efficient with the kind of coal we use. The other six boilers are served with chain-grate stokers that are driven from a lineshaft by a small engine. It is necessary to operate these boilers constantly at 175 per cent. of rating, and on peak periods they carry 225 per cent., using Indiana screenings and mine-run coal. Steam pressure is carried at 195 lb., with 100 deg. of superheat. Our load is divided about equally between commercial and railway power.

About four years ago the question of higher efficiency in the boiler room was under consideration at our plant, and we installed a system of automatic control of the draft and stokers that has given us continued satisfaction up to the present time at a total maintenance expense of about $12, and we have every reason to believe that it will render good service for years to come. Owing to the finer degree of regulation we were able to secure with this system of automatic control over our old method, our boiler rating was increased with a saving of about 14 per cent. in fuel. The variation of steam pressure was reduced from 20 to 5 lb., and the average CO_2 was increased materially. The boilers now require less cleaning inside and out owing to more complete burning of the coal and to the rapid circulation of the water, and the general expense on the upkeep of our furnaces has been lessened.

Our regulating system consists of a damper regulator *A* attached to two master dampers *B* and *C*, each 10 x 5 ft., which operate vertically in rectangular smoke breechings, one on either side of the chimney, which is 12 ft. in diameter and 225 ft. high. The regulator is actuated by the steam pressure, and the actuating beam releases a water pressure which, acting in a cylinder *D*, closes the two master dampers to the desired point within 30 sec. Simultaneously with the action of the water in the cylinder, the same pressure is transmitted to a special regulating valve *E* on the stoker-engine steam pipe, so that the speed of the stoker is cut to a point in relation to the closing of the dampers, and after hours of operation the fires are maintained at the proper thickness and length without manual effort. It is this particular feature of the equipment that distinctively places it in the efficient class. The design and connections of the master dampers are such that any desired degree of operation can be secured and also the stoker valve can be so adjusted as to be always in true relation to the operation of the dampers.

One of the most important features in connection with this system is a red signal lamp, which is suspended centrally in the boiler room. This signal is flashed the instant the regulator goes into action and remains burning until the dampers are closed again. This lamp is to the firemen what the compass is to the sailor, and without it the system would lose a great deal of its value. Should the light remain on more than two minutes at any period, it denotes that something is interfering with the boilers in meeting the demand for power. The flow meters will indicate whether it is an increase in load or not; if the load is regular, there has been a change in fuel and the proper adjustment is made on the stokers. Low steam pressure permits water pressure to open the dampers, and as soon as the normal steam pressure is regained, the dampers are released from the water-pressure cylinder and counterweights close the dampers.

With the increased load the plant now carries over that which it carried previous to this installation, three boilers in full operation meet all demands, the fourth being used as a buffer. Previous to the installation of the regulator four boilers were required at high service, with the fifth as a buffer. The initial cost of the regulator was met by the fuel saving effected during the trial period.

J. R. S. Low-Grade Fuel Burner

In these days of high-priced fuel and coal shortage throughout the country, manufacturers are turning their attention to perfecting devices that will burn the lower grades of fuel. Among others who have been working on the problem is the Mechanicville Specialty Supply Manufacturing Co., Mechanicville. N. Y., which is manufacturing the J. R. S. Low-Grade Fuel Burner. The object of this apparatus (Fig. 1) is to burn such

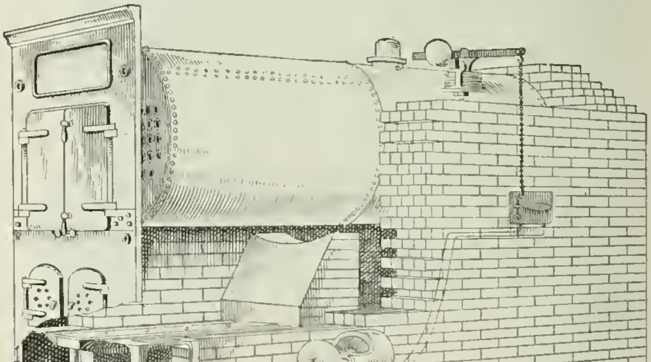

FIG. 1. BURNER AND DRAFT FAN AS APPLIED TO FURNACE

low-grade fuels as coal dust, screenings and buckwheat, both anthracite and bituminous coal, and especially such grades as cannot be burned with natural draft.

The burner is made of cast iron, as are also the "filling-plates." Two burners are usually placed in a furnace, the "fillers" being bolted to them. The burners are spaced so that about half of the width of the furnace is between them, and midway is an ash dump so constructed that it is practically gas-tight when closed. The design of the burner and also the ash dump is shown in Fig. 2.

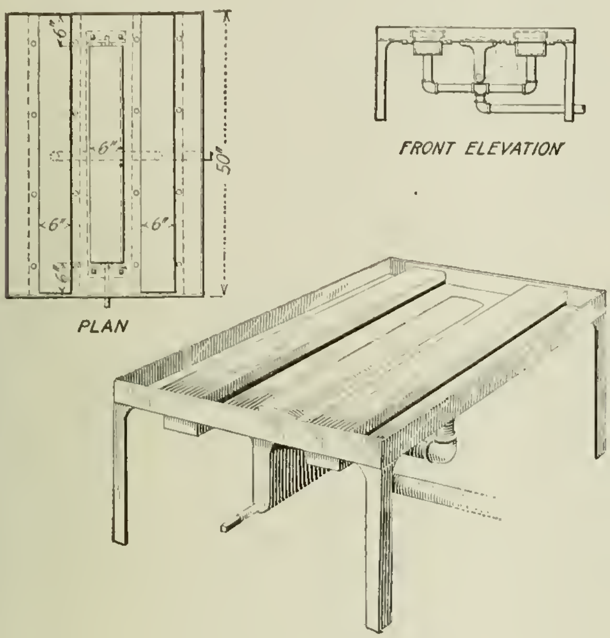

FIG. 2. DETAILS OF BURNER

No grates are used, and the edges of the burners, where they come against the brickwork, are sealed with a noncombustible substance so as to prevent the flow of air from the ashpit into the furnace.

Each burner consists of an air-box over which is a cover plate so separated from the box body proper that there is from $\frac{1}{2}$ to $\frac{5}{8}$ in. opening between them on the sides. In other words, the design is about what would be obtained with an ordinary cardboard shoe box with the cover a couple of sizes too large for it and lifted about one-half inch from the body. Air is supplied to the burner through a bottom connection, as shown. In the case of a double burner the air connection is made as indicated by the elevation in Fig. 2.

The discharge of air from the burner box is underneath the cover plate and along the two sides in a semilateral flow downward, and rebounding under a pressure at the points of discharge into the coal, it is distributed to the fuel surrounding the burner. The air pressure can be carried as high as 12 in. of water, thus enabling the operator to carry a heavy fire as is frequently necessary in plants that are operated at their full capacity. With a clean fire the draft would, of course, be much less than would be necessary with a heavy, dirty fire.

Air is supplied by means of either a direct-connected motor-driven or a belt-driven fan. The operation of the motor is controlled by a diaphragm-pressure regulator. For instance, if the damper regulator is set to control the steam pressure at 100 lb., the motor and blower will supply air to the fire until the steam pressure reaches that point. The diaphragm regulator then operates a switch and shuts down the motor. A drop in the steam pressure causes the regulator to throw the switch again to start the motor.

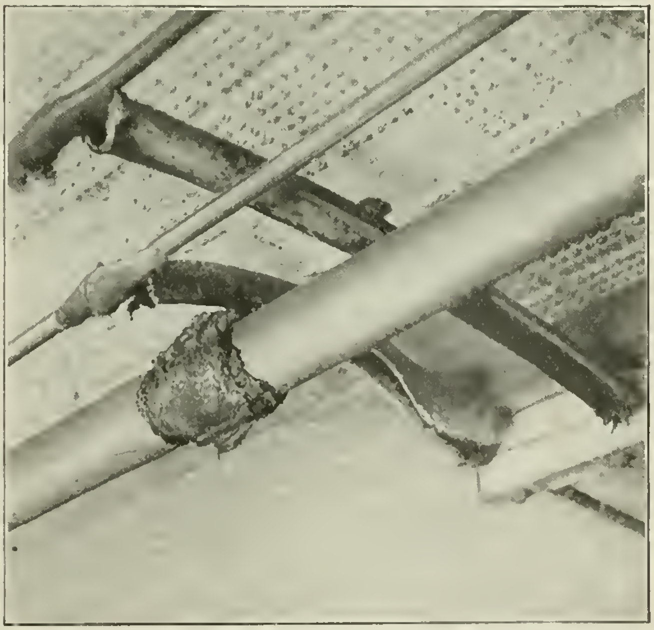
The fuel is fired as with the ordinary grate furnace, and the ashes are discharged into the ashpit through the dumping gate.

Lighting Circuit Caused Water-Pipe Joint To Corrode

By B. A. Briggs

The effects of eddy currents, produced by stray magnetic fields set up by alternating-current circuits, are probably not appreciated as much as they should be. The illustration is an example of what may happen to a pipe coupling where an alternating-current lighting circuit is installed near it. This installation is in a perfectly dry basement that is heated in the winter. The pipe line, which is used for water supply to the building, is only a few inches away from a ceiling covered with plaster boards.

The electric installation has been in use for a period of only about three years; previous to that time the joint was not corroded, neither has any other pipe joint, either gas or water, corroded in the building since the electric circuits were installed. Therefore it appears to be quite evident that the presence of the electric circuit at the pipe joint caused the corrosion. The corrosion had gone so far when this photograph was taken that in some places the threads of the coupling were visible.



ELECTRIC WIRING AND PIPE JOINT

[Although the foregoing is not positive proof that the presence of the lighting circuit caused the coupling to corrode, nevertheless it brings up the question as to the advisability of running electric circuits across a pipe coupling as in the figure. *Power* would appreciate an expression of opinion from interested readers for publication on the foregoing question.—Editor.]

Buying an Ash-Handling System

BY HERBERT E. BIRCH

How to intelligently purchase an ash-handling system to remove ashes from boiler ashpits is a question that is confronting many engineers and is discussed here. It is a timely subject, and there are many ways of solving this apparently simple problem.

TO ONE who is not thoroughly familiar with the effect of ashes on conveying machinery, it seems like a waste of time to give the subject much consideration, but it requires more thought to design or purchase ash-handling equipment than it does a system to convey coal. Any conveyor to handle coal may be installed with reasonable expectations of a minimum upkeep cost, but with ashes it is necessary to proceed cautiously, for there are many points that demand consideration.

Perhaps the first one is whether to install a single conveyor to handle both coal and ashes. The claim in favor of this method is that it avoids a multiplication of machines and driving parts and so reduces the cost of operation and maintenance. Against this, there are the claims of those who prefer a "divorced" system, where the ashes are handled in a conveyor set apart for that purpose only. Briefly, these are that it is often necessary to handle coal and ashes simultaneously, which it is impossible to do with the "one for all" conveyor; that the equipment runs only about one-tenth of the total time to handle ashes, and that it is subject to the wear of the ash grit in the chain joints the remaining nine-tenths; that wet ashes sometimes pack in the buckets and they have to be cleaned out before coal can be handled, and that inasmuch as the conveyor was made heavy and ponderous to resist the destructive effect of ashes, it is foolish to pull this extra load around the boiler room when handling coal.

MOST ENGINEERING FIRMS PREFER "DIVORCED" SYSTEM

These points must be carefully weighed before deciding which system to follow, but in this connection it may be well to state that most of the large engineering firms prefer and the large New York and Philadelphia boiler houses use the "divorced" system.

Assume that it is decided to follow in their footsteps and see just what there is to watch and where there is a probability of being tripped up by the salesmen who present for consideration the various systems on the market. Perhaps the best way to do this is to first look at the ashes—examine their make-up. It is well known how destructive a few grains of grit in a bearing would be. The ashes may be dripping wet, red-hot, dry and dusty, or hard with sharp corners, but they are never just plain ashes.

All of this suggests abrasion. Consider first what effect they will have on the system that is being investigated. Are there any chain joints or other moving parts that are likely to wear out? Perhaps there are no chains. Then do the ashes move in, over, or through anything? It does not make much difference whether they move and the part that wears out is stationary, or whether the ashes are stationary with respect to the moving part; wear occurs in any event, and the result is that the repair bill is high or, as often happens, the outfit is thrown out by someone higher up.

Power requirements often lead to the rejection of a conveying system, for power costs money. Will the apparatus under consideration consume much power? Will it use power at its maximum rate all the while it is in operation, or does it consume energy only while it is actually conveying its full load? Some systems operate under full power while the ashman is lighting his pipe or while it is conveying only at one-half its maximum capacity. Is the power consumption so large that it is necessary to keep 90 or 100 hp. continually floating on the line ready for ash-handling service at any instant? One argument for large power-consuming devices is that ashes are handled only when there is a large head of steam on that would be wasted anyway. Beware, for it is but a snare and a delusion. What is the intelligent engineer doing with so much steam to waste?

BREAKING THE CLINKERS

What size clinkers do the stokers make? Perhaps they are working under an overload and the clinkers are extremely hard. Must these clinkers be broken into small pieces before they can be fed into the conveyor, or can they be put in just as they come from the furnace? Do not let anyone minimize this point by suggesting that it is easy to put a concrete block at each conveyor intake upon which to break any recalcitrant clinker; plant operators are not in the butcher business.

Frequently it is desirable to get rid of boiler-room refuse by means of the ash conveyor. Will it handle firebrick, flue dust, soot, etc.? Do not take the salesman's say-so. Investigate, use common sense and find out.

How about dust prevention? Maybe the plant is at a textile or paper mill, where dust is frowned upon. Will the conveyor under consideration handle a finely powdered material and deliver it to the ash bin without kicking up a cloud of dust? If it will not, can it be wet and then will the conveyor handle it? Will the putty-like mass that is formed clog up the system and will it be necessary to poke it out in order to start the apparatus working again? Or, if it is handled dry and quenched just before it is discharged into the ash bin, is the quenching system subject to freezing in winter? Possibly, where steam is used as the propelling agent, mud will be produced, which is apt to cause trouble at the turns. Consider what happens to the ashes (or mud) in the conveyor when it stops handling them. Is it necessary to poke things clear before it is possible to start up next time? Is the mud likely to settle at the lowest point and cake there, and if it does, how easy is it to find where this occurs?

How about a dirty appearance around your plant? Will it be necessary to drop the ashes from the stoker hoppers and then rake them into the conveyor? An ashman is not apt to be overly clean in sweeping up after he is through, but can he be blamed?

How about safety? Some systems explode occasionally, doing severe property damage. See *Power*, page 468, Apr. 3, 1917. In this accident two men were killed.

The capacity of the system should be of interest also. It is possible that it will take several men to tease the ashes through an intake opening in order to handle the amount that is made. Then there is the distance the system will convey the ashes and the height to which it will lift them. Perhaps if there is a long run in the basement and a good high lift, the power consumption will be enormous.

NOISE A FACTOR TO BE CONSIDERED

Another factor that may influence judgment is the noise the apparatus is likely to make. Some conveyors emit a grinding noise which is extremely disagreeable to those who live close by. At several plants, the municipal authorities prohibit the conveyor working at night, and at least one, to my knowledge, was refused permission to operate on the ground that it was a common nuisance.

Will the proposed installation meet the exacting demands of the *OMIA* formula? This means that operating charges O plus maintenance charges M plus interest on the total money invested I plus the adaptability A of the plant (which can hardly be measured in dollars) must be less than the labor saving effected. Operating cost includes power, labor to operate, oil and such incidentals. Maintenance charges include all repairs of any nature whatever and the labor expended in making these repairs. Under this head is usually included depreciation, which is likely to be high in an ash-handling plant. Conveying-machinery depreciation is figured at 10 per cent., but in some types of ash conveyors, where no machinery is used, the depreciation is likely to be 30 or 40 per cent.

Interest on the investment includes not only the interest on the parts purchased from the manufacturer, but on the cost of labor to install, foundations, and any preparatory work that may have to be done, bunkers built, etc.

OPERATING COSTS

Just a word in passing from this phase to the next. Do not be fooled by the oft-repeated statements of "a few cents per ton to handle ashes." Just figure it out. At 30c. an hour for labor, if 5 tons of ashes are handled per hour with the system, that is 6c. per ton for labor alone. How about power, which is apt to cost 20c. per ton in some systems? The cost per ton to handle ashes is determined by dividing the *OMI* cost per year by the tons of ashes handled. If an ash-handling system is already being operated, sit down right now and figure it out, but be prepared in advance for a big surprise. Instead of 6c. per ton it is more likely to be 30 to 40c. Then perhaps one will wonder just what is the trouble with a wheelbarrow, which has no operating difficulties, interest, maintenance and other charges to speak of. It may be that if an "educated wheelbarrow," with ball bearings and four wheels running on tracks is used, it would prove to be just about the right thing. There will be use for a man anyway, so why not let him push the wheelbarrow?

Speaking of having to have a man is a reminder that there is an opportunity to say just a little about the design of ash hoppers. If the plant runs night and day, the ash hoppers ought to be large enough to take care of the accumulation of ashes during the night and thus avoid a night shift of ashmen. The best condition is where all the ashes can be handled by one shift. It would probably be advisable to figure out how much labor would be saved by rearranging the ash hoppers to accomplish this, and determine what could be spent to do the job. Roughly, an expenditure of about $2200 is warranted for every dollar per day saved.

The engineer who spends his time thinking of such problems as this is the one who grows. Such a man cannot be kept down. Let someone else polish the brasses, or else do away with them, for if a man thinks and acts in such small terms, then surely will the real job, the job worthy of an engineer, be taken from him.

ASH-HANDLING METHODS THAT MAY BE USED

Now to get back to ash conveyors. The following methods may be used to handle ashes:

1. By vacuum systems, which are divided into two classes: (a) Complete vacuum systems, where the vacuum is maintained by exhausting the air from the ash bin; (b) partial vacuum, where the jet of steam creates a vacuum in the conveyor pipe back of the jet, but where the jet itself has a positive action on the ashes ahead of it.

2. Ash drag in a trench in front of the boilers or in a tunnel beneath the ash hoppers. This drag consists of a wide malleable chain running in a cast-iron trough and dragging the ashes with it. It may discharge to another drag conveyor which operates on an incline, or it may discharge to a:

3. Bucket elevator of the centrifugal discharge type, which is usually vertical or but slightly inclined. This bucket elevator may be used in connection with wheelbarrows or a push car.

4. Ashes skip hoist, which consists of a large bucket that runs up steel guides and dumps into an ash bin. This system is usually arranged so that the operator pushes a button and the bucket full of ashes ascends, dumps, reverses and descends automatically, coming to a stop in the loading pit. This skip hoist can operate in a vertical path or on an incline of, say, 45 deg., or anything between these two conditions. The skip bucket may be filled by means of a push car, wheelbarrow or ash drag. In the last case, it becomes necessary to provide an equalizing hopper to take care of the ashes which accumulate while the skip bucket is hoisting a load. (This is always necessary where a continuous conveyor delivers to an intermittent one.)

5. A grab bucket operated by a monorail crane may be used to dig ashes out of a pit where they have been discharged, by barrow, push car, steam jet or ash drag. The pit is then made large enough to take care of storage, thus eliminating the overhead bunker. However, an experienced man is usually required to operate a grab-bucket crane, which is one disadvantage of handling ashes in this way.

6. Cold ashes can be handled on a belt conveyor, but if the clinkers are large the belt must be wide, say 36 in. for large clinkers, unless they can be broken.

This applies to several of the other types of conveyors, where the clinkers have to be broken before they can be teased through a 6-in. hole.

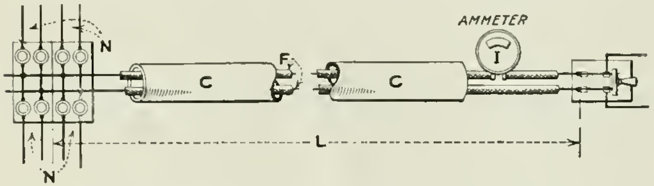
The foregoing are the principal methods used, and although others may exist, they are of minor importance. Even No. 6 could be omitted, but was mentioned to bring out the point about the clinkers.

Get acquainted with the various methods, applying to each the points mentioned in this article and then you will be in an excellent position to recommend the type of equipment to buy. The boss will not be in a mood to accept excuses when it becomes necessary to throw out a bad investment, but you will never be in this position if a little study is given to the subject now.

Conduit and Wire Sizes for Two-Wire Feeders

By T. A. Nash

A table showing what size conductors will be required to carry different numbers of 660-watt branch circuits with a 2 per cent. or a 3 per cent. drop is given herewith. The first column indicates the number of 660-watt circuits in each case. The second column, headed "Amperes," indicates the approximate number of amperes in each case, and the third column shows the smallest size of wire that can be used for the feeder without excessive heating of the wire. The fourth column indicates the normal size of conduit that can be used, assuming double-braided, rubber-covered wires are installed. The fifth and sixth columns indicate respectively the maximum distances to which the currents indicated in column *I* can be carried in the wire size of column *F* with a 2 per cent. drop and with a 3 per cent. drop. An indication of what the table stands for in the circuit is given in the figure; the letters at the top of the columns correspond to those on the illustration.



FEEDER AND BRANCH CIRCUITS

TABLE SHOWING FEEDER AND CONDUIT SIZES FOR 110-VOLT TWO-WIRE SYSTEM

N Number of 660-Watt Circuits	I Amperes	F Size of Feeder	C Size of Conduit for Rubber-Covered Wire	L Extreme Distance for 2 per Cent. Drop	L Extreme Distance for 3 per Cent. Drop

Operating Costs of Electric Elevators

By Charles W. Naylor

Chief Engineer, Marshall Field & Co., Chicago; Member A. S. M. E.

The electric passenger elevator has now been in service for a period long enough to enable the engineer to report intelligently on its cost of operation, maintenance and repair. Hitherto, reports on electric-elevator costs have been in a great measure based on tests made at the time of, or very soon after, installation, and the real cost, such as could be shown only by records of years of operation, has in the main been a matter of conjecture. The repair or maintenance side of the ledger, in which cost records are tabulated, shows a marked increase as the machine becomes older, after making due allowance for the advance in the cost price or repairs, which is now so noticeable.

This article will be based on the records for ten years, ended Dec. 31, 1916, for 50 worm-gear, drum-type elevators having a 150- to 230-ft. lift and running in passenger service at a maximum speed, loaded, of 350 ft. per min. The elevators cited are all in one building, operated in a similar manner, doing exactly the same kind of work for equal numbers of hours per day, and cared for by the same set of mechanics, using the same oils, grease, cables, ropes, brushes, etc.

They are all of the overhead drum type, as shown in the figure, overbalanced as to counterweight and equipped with all the standard accessories that go with this make of elevator. They are operated on direct current at about 226 to 230 volts, with magnet control of the usual construction and steel guide rails for cars and counterweights. There are two sets of counterweights, one for the drum and one for the car. All cables are standard, ¾ in. diameter, running over idler sheaves and drums of approximately 46 in. diameter. The car-counterweight cables, two in number, pass directly over the vibrating or idler sheave *A*, while the car-hoisting cables wind on the drum *B* as the drum-counterweight cables unwind, and vice versa.

There are no equalizing or compensating cables or chains. The cars, or cages, of a rather heavy pattern, weigh approximately 4000 lb. each, and the double counterweights about 5000 lb. The drums are driven by double, or fore-and-aft, bronze worm gears meshing with steel worms on an extension of the armature shaft, with the magnet brake installed on this shaft between the armature and the worm. The armature revolves at 850 r.p.m. when on high speed, and the drums make about 30 revolutions during the same period. Of the cars listed, five have a travel, or rise, of 150 ft., forty have 200 ft. and five 220 to 230 feet.

In addition to the overhead type of passenger cars, there are five machines of the basement type, the driving mechanism being at the lower landing, with traveling idler sheaves over the drum. The lift is about 40 ft. For the various items shown in the table the operating costs are about the same. The extra cable wear is in a measure compensated for by the shorter length, the cables wearing out in two or three years as against six to ten years for the longer lifts. There are also 11 freight elevators of overhead type, 220 ft. travel, with a somewhat slower speed and smaller motors. These machines cost 10 per cent. less for all items shown in the table, except for cables, and 50 per cent. less for these. Their speed is 250 ft. per min., and they travel about 6 to 8 miles per day as against 12 to 15 miles each per day for the passenger cars.

The labor shown is for the wages of the maintenance and repair mechanics. Each man cares for 12 cars, oiling, cleaning, adjusting and ordinary repairs. Two extra men care for the heavy and extraordinary repairs such as installing armatures, greasing guides and putting on cables. The increase from year to year is occasioned by some additional help and wages advanced for the old employees.

The item miscellaneous includes leather for brakes, copper rivets, babbitt, bolts, screws, etc. The armature expense is mostly for rewinding and includes a few field-coil renewals. The repair item includes brushes, controller disks, contact lugs, carbons and such material as would naturally be purchased from the manufacturer of the machine, used mostly in keeping up the controller boards. Oil includes engine oil for bearings and guides and castor or castor-machine oil for the worm cases. Cables include the ¾-in. main cables and the ½-in. wire and ⅝-in. manila rope for the governors.

MAINTENANCE COSTS OVER 10 YEARS FOR 50 ELECTRIC ELEVATORS *

	1907	1908	1909	1910	1911	1912	1913	1914	1915	1916	Total	Average
Oil	93	93	93	68	68	110	110	78	92	52	857	86
Grease	8	16	16	25	26	34	28	29	31	9	222	22
Repairs	425	1,105	618	465	467	603	119	40	39	96	3,977	398
Armatures	1,060	1,160	461	1,148	935	540	918	580	660	362	7,824	782
Cables		467	188	323	140	174	213	316	360	1,012	3,193	319
Labor	5,000	5,000	5,525	5,525	5,525	6,375	6,375	6,450	6,450	7,650	59,875	5,988
Misc	110	59	307	238	344	170	269	84	270	92	1,943	194
Total	6,696	7,900	7,208	7,792	7,505	8,006	8,032	7,577	7,902	9,273	77,891	7,789
Per car	134	158	145	156	150	160	161	151	158	185	1,558	156

* For simplicity all amounts given to the nearest dollar.

Each passenger car travels about 13 miles per day, and for the year of 310 days, totals 4030 miles. Dividing the average annual cost per car by this mileage gives a maintenance cost of $0.0387 per car mile, of which about 75 per cent. is for labor and 25 per cent. for materials and supplies.

In the same plant are 11 worm-gear one-to-one traction machines having 230 ft. rise in the hatchway, with compensating chains. The cars travel 375 ft. per min., or 14 to 16 miles per day. Maintenance costs at present are about the same as for the old drum types, except for cables, which wear out about twice as fast as they do on the drum machines. These elevators are now only three years old, and it is too early to pass upon their real cost of operation.

There are also five basement worm-gear one-to-one traction machines with compensating cables, having 140 ft. lift and a speed of 300 ft. per min. The ropes on these machines wear out very rapidly.

In addition to the foregoing there are eight one-to-one overhead traction machines having 280 ft. lift, 450 ft. speed and equipped with compensating cables and weights. The cars travel about 20 miles per day each, and the cables are wearing out three times as rapidly as those on the old drum machines. These cars having been in use only three years, it is wisdom to defer decision on their operating cost to a later date.

In the plant there are 77 passenger and 14 freight elevators traveling about 1500 miles and carrying from 150,000 to 325,000 passengers per day. The cost per car-mile for current is practically the same for all types. A future article will deal with some of the many operating troubles peculiar to these machines.

The Fuel Administration Mandate

THE practical suspension of business by the Fuel Administration for five days and for a day each week for seven weeks to come, was one of the largest exercises of governmental authority to which industry has ever been asked to submit. If it effects its purpose, Fuel Administrator Garfield is entitled to a meed of credit proportional to the magnitude of the exigency and the boldness of the remedial act.

The execution of such a measure can be justified only by the existence of a condition of the utmost gravity; its wisdom can be demonstrated only by the extent to which it is effective in mitigating that condition.

In the first place its primary object was not the saving of fuel, but the slowing up of production. Industries, speeded to the utmost, were piling upon the already overburdened railways, goods for transportation to the seaboard. Ships could not be coaled fast enough to take the goods away. Terminals were congested, cars were held up and the roads and sidings were blocked, interfering with the transportation of the coal needed to relieve the situation. The effect was cumulative. Much as some of the goods were wanted, it was bootless to make them simply to be piled up in the cars which might be hauling coal and which were standing in the way of trains that might relieve the coal famine.

Could the railroads have been speeded up enough to overtake the accumulation and at the same time take care of the daily increase? Those who are in the best position to know say that they could not. Could the manufacture or shipping of nonessentials have been suspended? Several days were lost in proving this to be impracticable. And so, in the light of what they know, and what the man on the street does not know, those responsible for results said, "We must stop and let the roads catch up, or go on from worse to worse." To have announced their intention to do this would have aroused such remonstrance and have set into operation so much machinery of opposition as to render it impossible, and would have so speeded up production in the interim as to further swamp the roads and further deplete the diminished coal supply, to say nothing of its effect upon the market.

It had to come, as it did come, like a bolt out of the blue; and before some of our good people could weigh the petty sacrifice that they were asked to make against the supreme sacrifice that those are making to whose support this order ultimately means the most, there arose a storm of indignant protest, which has subsided at this writing to an attitude of quiescent submission, and which we hope as this is read will have changed to one of intelligent appreciation and approval.

The importance of the fuel supply, even to interests to which it seems but remotely related, has been demonstrated this winter as never before. The orderly conduct of the procurement and distribution of that supply is a matter of the utmost concern to the whole people. The organization of a system for such control out of a mass of competing units, with a crippled railway system, in a winter of unwonted severity, and against the covert opposition of those who do not wish to see the practicability of government control successfully demonstrated, is not the work of a week or of a season. Without the Fuel Administration there would have been a coal shortage fully as acute as the present—for the mines now are turning out all that the roads can haul —and prices would have soared unrestrained.

Let us have patience until the machine gets warmed up. Let us not go into hysterics if it skips a stroke now and then. Back up the Administration until it has a chance to put into effect some of the measures now in view and in development, and this year's condition will be pointed to as an example of those which intelligent organization in the interest of over-all efficiency can correct.

The Day of the Recording Instrument

NOT many years ago the recording instrument in the average plant was a rarity. Its use was considered superfluous, and if perchance an instrument of this type did find its way into a plant, its possibilities were not fully appreciated. Considered more in the light of an ornament, there was no great incentive to maintain it in accurate working order, and more often than not the records would be dumped into a drawer of the engineer's desk or perhaps filed away for safe keeping. Those were the days of cheap fuel when a few tons of coal, one way or the other, was not seriously considered. Conditions were not severe, and the indicating instrument did very well. Plants fully equipped did better than those with no precise measuring instruments, and if the meters were read often enough, the time indicated in each case and plots afterward made, a rough approximation of the register of a recording instrument was obtained.

Securing complete operating data in this way and the subsequent plotting were tasks too arduous for the average operator. More than occasional readings could not be expected. Comparison of the value of data obtained in this way and of time records from accurate instruments recording every variation of the quantity measured and transcribing it so that the range over the entire period may be read at a glance, is not difficult to make. With the proper number of instruments simultaneous records giving complete operating data for the station are at hand ready for analysis, and as the records are permanent, comparison with previous performance is easy.

There is no need, however, of championing the recording instrument. It is already with us. Its merit has been proved, and its adoption even in the smaller plants is becoming more general. The war, the urgent demand for coal, the rise in price and the necessity for efficient production have been contributing factors. In these days coal must be conserved for military purposes.

The small plant is working on a closer margin than ever before. It must be fortified in every way possible and must conduct its business intelligently, complete and accurate data being the first essential.

Those plants which have been getting along comfortably in the past with incomplete indications of operating conditions, cannot afford to continue in the old way. The recording instrument offers a decided advantage. There has been a big development in this field. More and better instruments than ever before are available. Coal must be saved. A wise selection of meters, showing the operator exactly what is being done in the plant and where improvement is possible, is the first step.

How Do You Mix Your Fuel?

ONE of the most urgent problems that now confront the engineer is the utilization of the lower grades of coal, such for example, as screenings and culm. It has been supposed that the culm piles were pretty well cleaned out, but the fuel shortage has developed that there are great quantities still available and at a price that makes it worth while to attempt burning it when mixed with soft coal.

There immediately arises, then, the problem of mixing the culm or screenings and the soft coal so that when used in stokers the mixture will be sent to the stoker hoppers in such way that there will not be a segregation of the lumps as the fuel goes to the stokers. Should this happen, it is almost impossible to prevent holes in the fire of so serious a nature as to make combustion not only uneconomical, but difficult to carry on. Obviously, the problem is a local one and the conditions in each particular plant will require different measures for its most successful solution.

Engineers are greatly interested to know how the other fellow is doing it, and *Power* extends an invitation to those who have met this problem to tell how they have met it and what troubles they have encountered in mixing the fine, powdery fuel with the run-of-mine coal. What proportions are found most suitable for particular types of stokers with particular settings and for the various loads? In hand-fired plants it is a simple matter to mix the culm with the soft coal, but where crushers are used and where the coal is conveyed to an overhead bunker and then gravitates to the stoker hoppers, it is not so easy to get the best mixture.

It is quite important that engineers learn how to burn culm and other very low-grade fuels, especially those which are byproducts of mining and which, unless used, may stand for years in huge piles exposed to the atmosphere, thereby suffering deterioration in heating value. The sooner such fuels are used after they come from the mines, the greater their value.

Let us know how you get your mixture and how you crush, convey and feed the fuel.

Alaska's Coal

WHEN Secretary Seward bought Alaska for the United States no man was, perhaps, on the day of the consummation of the sale, regarded as a greater fool than he. But time and research have revealed the wealth of resources that lie buried beneath the chilly surface of our most northern possession. And Seward's judgment is vindicated.

One of Alaska's greatest assets is coal. At this time that sounds inspiring; it is like the answer to a shipwrecked sailor's signal. The Geological Survey estimates that Alaska treasures more coal than did Pennsylvania before that commonwealth's coffers were tapped.

Is not the Seattle Chamber of Commerce then to be congratulated for at this critical time calling attention to the possibilities Alaskan coal offers for supplying the West and Northwest? Think what it would mean to the eastern half of the United States if now the present mines had to supply only the East. Every ton of coal that can be spared is sent to the Pacific Coast via the Panama Canal, and enormous quantities are sent from the East over the rails to the remote West. It is reported that 25,000 cars of coal started for the Lakes, to be shipped by water into the Northwest, arrived after navigation closed and that these bearers of the treasure still lie sidetracked somewhere. Maybe the report is true; but it seems incredible that it should not have been carried on to its ultimate destination by rail or dumped into the Middle West, where coal shortage has driven mayors and at least one governor to extreme measures to get relief.

The oils of the Pacific Coast by no means offer great and continuous supply of that fuel. The country west of the Rockies is growing, and with the growth the demand for coal increases proportionately. The railroad congestion and coal crisis have taught the value of using that fuel nearest the place of consumption. The Government could do no greater service to the nation than to be most reasonable in promoting the development of coal mining in Alaska. Doing so would doubtless lend impetus to industrial growth not only in Alaska, but all down the Pacific Coast and as far inland as that coal can be economically transported.

Why New York Has No Coal

AS THIS issue goes to press there is talk of pooling the anthracite coal for New York City and southern New England. Much of this coal comes in over the rails to Perth Amboy, N. J., from which it goes by barge to the sections of the country where it is consumed.

What pooling the anthracite arriving at this port will do to relieve the critical conditions, provided labor and other vital factors are properly cared for, may be judged by reading the account of conditions at this port as given on pages 178 and 179. There is no need of going into particulars here, as they are given in the article; suffice it to say that conditions there are deplorable.

J. D. A. Morrow, Secretary of the National Coal Association, has been appointed by Dr. Garfield to assume general charge of distribution. This is a most commendable move. Certainly, no part of the whole coal problem is in need of greater and competent attention than that of distribution. Mr. Morrow's experience fits him for his new job. Certainly, it is the hope of all Atlantic Coast sections of the country that Mr. Morrow will not only get the authority he will need to accomplish results, but will use it fearlessly when he gets it. Hampton Roads, New England and the New Jersey ports have plenty for him to do.

The Reason There Is No Coal

That the coal-unloading piers are the key to the critical coal situation in New York City is clearly evident from the following, which is from a recent report of the Coal Conservation Committee of New York State.

THE following are the docks with the railroad serving each: Undercliff, Erie R.R.; Weehawken, N. Y., O. & W. R.R.; Hoboken, D., L. & W. R.R.; Port Liberty, C. R.R. of N. J.; Port Johnson, C. R.R. of N. J.; Port Reading, P. & R. Ry.; Elizabethport, C. R.R. of N. J.; Perth Amboy, L. V. R.R.; S. Amboy, Penn. R.R.; St. George, B. & O. R.R.

Capacities are based on what it is estimated the docks can do under normal weather conditions. The total tonnages of the docks on this basis are 2615 cars per day. Averaging a car at 40 tons, this would amount to from 100,000 to 110,000 tons per day.

The following figures were given as representing a fair average cars per day for the dumpings under normal winter conditions: Undercliff 150 to 160, Weehawken 115 to 120, Hoboken 225 to 250, Port Liberty 60 to 70, Port Johnson 60 to 75, Elizabethport 75 to 100, Port Reading 225 to 275, Perth Amboy 150 to 200, South Amboy 300 to 325, St. George 75 to 100. A total of 1675 cars on the outside figures, or in tonnage a matter of 65,000 to 70,000 tons.

Thawing Facilities—Undercliff: Covered steam house with capacity for 48 cars at one setting; also have spear system with accommodation for 8 cars at one setting, or total of 56 cars. The house is old, having been used for a number of years; the average time required to thaw coal in this house being approximately six hours. Spear system requires about the same length of time by reason of the fact that an insufficient number of spears are applied to each car.

Weehawken: Spear system in use; accommodation for 40 cars at one setting; average length of time for steaming, 4 hours.

Hoboken: Spear system; accommodation for 40 cars at one setting; average time, 4 hours.

Port Liberty: No facilities for steaming.

Port Johnson: No facilities up to this date. One locomotive is being put into operation to furnish steam.

Elizabethport: No steam plant, coal being thawed by use of locomotive. One locomotive can take care of two cars at one setting. The number of locomotives furnished for this purpose is two, thawing out four cars at one setting; one pipe being applied to each car, and average time for steaming forty-five minutes to a car.

Port Reading: House steam equipment for 44 cars at one setting. Time required, two hours on bituminous steam coal, and on anthracite fine sizes several hours.

Perth Amboy: Spear system equipment for 24 cars at one setting, average time of steaming, 3 hours.

South Amboy: House steam, capacity for 40 cars at one setting; average time, 2 to 4 hours.

St. George: No steaming facilities. At St. George a steam plant accommodating 40 cars will be ready for use in a few days.

Perth Amboy: The Lehigh Valley expect to have a new plant ready some time in February which will increase their capacity to 96 cars. This plant was ordered long ago and was originally promised for delivery on Aug. 1, last.

With reference to labor, the following docks are short: Undercliff, Weehawken, Hoboken and Port Reading.

Aside from the question of shortage of labor, most of the piers are handicapped by "green labor."

South Amboy now operating 24 hours, is not operating to capacity by reason of insufficient coal supply. This port could load more tonnage.

Undercliff, which is working on a 10-hour basis, could materially increase its tonnage if put on a 24-hour basis.

In addition to this if steaming facilities could be promptly devised, such as furnishing locomotives, Port Liberty, Port Johnson and Elizabethport could load more tonnage by working 24 hours.

At the pier at Undercliff, Weehawken, on the morning of the 27th, there were available for individual shippers 142 cars of which only 45 cars could be released that day on account of no individual shipper apparently having sufficient coal of proper sizes to make a cargo beyond 45 cars.

It seems that at this time there is ample equipment to take care of the movement of coal from piers to harbor points.

The Conservation Committee recommends to Mr. Wiggin, Fuel Administrator for New York State:

1. That a practical railroad official directly connected with or in charge of each dock, meet at 2:30 Friday at this office and be empowered to coöperate with this committee, to go more fully into this matter, and make any practical recommendations that they think will be necessary to meet this critical situation.

2. It is recommended that all docks immediately arrange to work twenty-four hours daily.

3. That all docks increase their steaming facilities for the thawing of this frozen coal to the maximum immediately.

4. That this committee recommend the pooling of all coal so that no additional time may be lost in switching.

5. That this committee recommend that any culm, silt or any anthracite steam sizes containing material that will pass through a one-sixteenth inch mesh, otherwise dirt, be temporarily eliminated until such time as all the larger sizes of coal be dumped, as it is found upon investigation that the time consumed in unloading a car of this coal materially interfered with unloading other sizes.

6. It is recommended after our investigation that every effort be made to increase labor and the locomotive service at these docks, which is found to be inadequate.

7. That the docks work Sundays and holidays till the present stringency is past.

These recommendations have been in the hands of the national, state and city fuel administrators long enough for action. The conditions are more severe than this report reveals, as will be told on the editorial pages of next week's issue.

Correspondence

Coal Shortage and the Southern Power-Plant Operator

With the demand for coal exceeding the production by thousands of tons, there must of course be less consumed to prevent crippling industries dependent on coal for power. Everything possible should be done to lessen the serious fuel famine in the East, where hundreds of highly necessary industrial enterprises are located, and partially solve the fuel problem. After giving the matter careful thought and after visiting hundreds of power plants in the South, I have come to the conclusion that one solution of the difficulty would be to use wood for fuel. The South has an abundance of various kinds of wood that could be used.

About 50 per cent. of the South's population is rural or in towns up to ten thousand population. In these towns there are power plants which develop from a hundred to a thousand horsepower and consume thousands of tons of coal. Ninety per cent. of the boilers in these plants are of the horizontal type and can easily be converted from coal to wood burners, and at the present prices of coal the change would be economical in many cases, even though the various heat losses should increase. It may seem that the labor cost in stoking would increase, but a close study of local conditions shows that there will be a reduction instead.

January and February are months of little activity with team owners and common labor, so that wood could be cut and hauled in these months at a very low price. Four-foot wood seems to be preferable as it dries quickly and can be handled easily. When trees of from six to twelve inches in diameter are cut, the wood should be quartered and stacked on end. If cut into smaller pieces, the fire burns too fast and the furnace doors have to be opened too often, in firing, to allow a steady combustion; but the larger size can be handled easily, and the fire can be kept burning constantly with a minimum of door manipulation. If the removal of the bridge-wall becomes necessary, it will neither affect the draft nor increase the fuel consumption to any extent. It has been my experience that it is possible to fire both on the grate bars and partly in the combustion chamber with good results. With coal, of course, this would be absurd, but wood will burn well in such a position and not simply char as might be expected. If green wood is being used, one must keep the furnace full so as to produce a drying condition. At each firing the dry wood should be raked from the combustion chamber to the fore part of the grates; in this way the fire will be constantly replenished with dry and partly ignited wood. In stoking one must be careful not to injure the blowoff pipe. To avoid this an iron bar might be placed in front of it to check a blow that might occur.

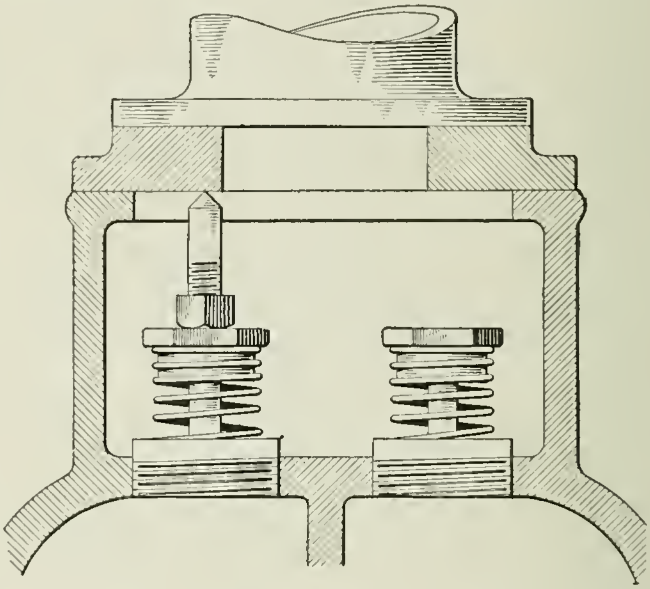
With a careful study, expenses can be minimized and the consumption of wood can be reduced by timing the stoking and feeding the water into the boiler as the intensity of the heat varies. By heavy firing the labor is reduced and one man can stoke just as many boilers as when burning coal. Experience will enable the fireman to work his fire, draft and water in such a way as to keep steam constantly at the desired pressure.

Newport News, Va. G. N. McIlhenny.

An Emergency Pump Repair

When a 12 x 7 x 12-in. duplex pump in our plant failed to supply its full amount of water and began to "cut up capers," it was shut down and the handhole plates were removed from the valve chamber on the water end. One valve seat, valve and spring were found out of place, for the threads had stripped on the valve seat, allowing it to be forced out of place. The pump was urgently needed, so it was repaired temporarily by cutting a piece of $\frac{5}{8}$-in. round iron the right length to reach from the top of the valve stem to the top of the inside of the valve chamber. One end was threaded and a $\frac{5}{8}$-in. nut screwed on the thickness of the nut; the upper end was pointed as shown in the illustration. The valve seat was wrapped and "doped" with red lead. The bolt was put in place and then backed part way out of the nut, forcing the seat down tight into its place and holding it there. The pump was out of service only a few minutes. E. M. Keys.

Montesano, Wash.



IMPROVISED JACK TO HOLD VALVE SEAT IN PLACE

How To Distinguish Iron from Steel Pipe

Those who specify wrought-iron pipe should be able to determine whether the pipe delivered to them is actually iron or not, and in the case of old pipe it is also interesting to know whether it is iron or steel. Four different test methods may be used for distinguishing iron from steel, and these are, in the order of the ease with which they may be made, as follows:

1. Crushing Test: Cut a ring an inch or two wide from a length of pipe and hammer it flat, so as to obtain a fracture. The structure of iron is fibrous, while steel is crystalline. Steel is difficult to fracture, and the fracture is bright crystalline; iron is more easily fractured, and the fracture is distinctly fibrous and of a dull gray tone.

2. Rough Etching Test: Submerge one end of a test piece in a solution of equal parts sulphuric acid and water. After five or ten minutes the end of pipe, if iron, will begin to show a number of fine concentric rings just as though it had been made from a number of sheets of paper pasted together. This appearance is caused by the acid eating away the iron more quickly than the noncorrodible layers of slag popularly referred to as "cinder-rings." Steel has no slag incorporation, therefore will show smooth, without layers. The acid or any other accelerated test is no indication of the rust resistance of metals in service, for the acid dissolves the metal, while corrosion in service is a gradual combination of iron and oxygen, forming rust.

3. Microscopic Examination: The surface of the metal when highly polished will exhibit the structure—the crystalline structure of steel, and in wrought iron, the even grains and slag inclusions in the form of irregular but extremely fine strands or fibers of slag separating the grains of iron.

4. Chemical Analysis: The chief differences are the relatively high silicon and low manganese content of iron, and the analyses will show about as follows:

	Iron Pipe, Per Cent.	Steel Pipe, Per Cent.
Silicon ...	0.15	0.05
Manganese. ..	0.05	0.30
Sulphur ...	0.02	0.05
Phosphorus	0.15	0.10
Carbon	0.04	0.13

The high silicon in iron is due to the slag content, which is actually as high as 6 per cent. (by volume) in iron; but this is not shown in ordinary chemical analysis, as the slag is not chemically combined with the iron. The higher manganese in bessemer steel is the result of overoxidation of the metal and the addition of manganese to the molten mass to make it suitable for rolling and welding.

Using a Pitot Tube

The article in the issue of Oct. 23, page 557, by W. V. White, on the pitot tube, impresses me as misleading, as it contains many statements that are incorrect. I have used a standard pitometer for measuring and checking the individual discharge from some twenty-five pumps, rated at 13 to 52 cu.ft. per sec., and probably a brief description of our method will be of value to readers of *Power*.

Our pitometer is shown diagrammatically in Fig. 1. There are two tubes, one within the other, and connected by rubber tubes at the top at *D* and *E*. At the bottom a small opening in each tube allows the outside pressure to be transmitted independently to each tube. These openings stand at 90 deg. to each other, as shown at A_1 and A_2, and when the flow in the pipe is in the direction indicated by the arrow, the pressure in the outer tube is the static pressure or head, and that in the inner tube the static head plus the velocity head, as this aperture receives the pressure due to the impact of the flowing water. These pressures, when transmitted through the hose to the U-tube or differential gage, produce a difference in level of the balancing fluid, proportional to the velocity head. This balancing fluid must, of course, be heavier than water, else there would be a continuous flow from the high- to the low-pressure side. For high velocities we use mercury, and for low velocity carbon tetrachloride, which is about 1.6 times as heavy as water and will not mix with it. By coloring the tetrachloride with a little cochineal, a sharp line of demarcation is produced. This deflection of the balancing fluid shown as H_v does not represent the velocity head. It is partly balanced by a column of water of equal height in the opposite leg of the U-tube. Assuming the specific gravity of the fluid to be S, as compared with water, then the difference in pressure between the two sides would be equal to $(H_v \times S) - (H_v \times 1)$ or $H_v\ (S - 1)$. Theoretically, the velocity would be $V = \sqrt{2gH_v\ (S - 1)}$. But here the formula must be modified. It is found that the actual deflection H_v is more than the actual velocity warrants, owing to the various shapes of the orifices, their positions, etc. Hence

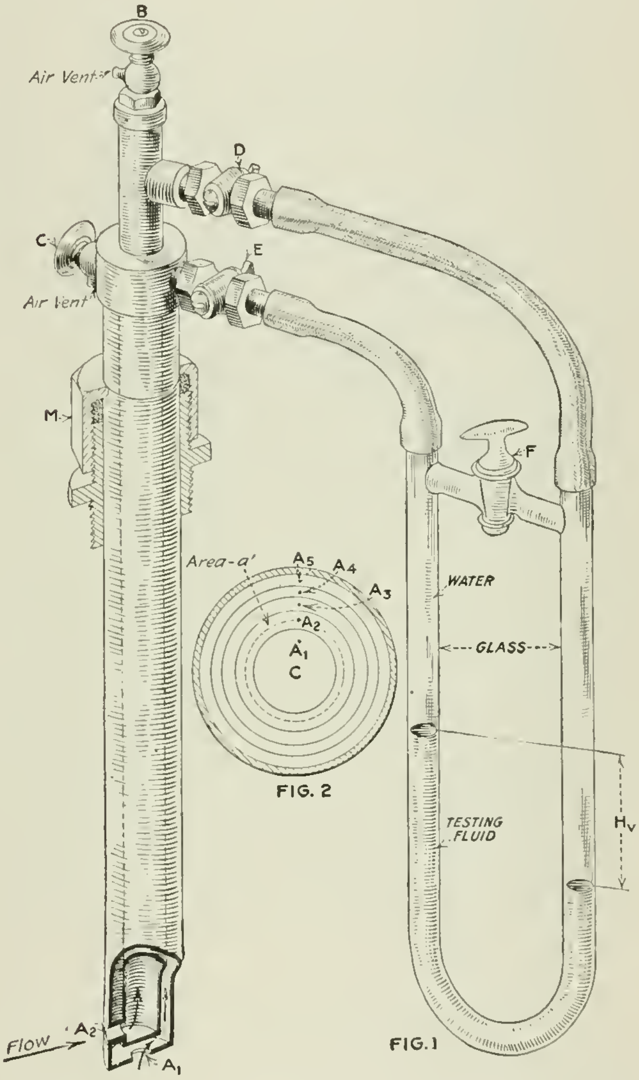

FIG. 2

FIG. 1

PITOMETER FOR DETERMINING FLOW IN PIPES

the value $\sqrt{2gH(S-1)}$ is modified by a constant C called the coefficient of the pitometer. Then the actual velocity would be $V = C\sqrt{2gH_v(S-1)}$. This coefficient is obtained for each instrument by towing the tube through a body of still water at a known velocity and noting the deflection H.

It is worse than useless to assume that any point in a pipe represents conditions of average flow. The point varies with every pipe and may not be in the same place twice in the same pipe, if the delivery is increased or diminished, as shown in hundreds of tests. The only reliable way is dividing the cross-section of the pipe into a number of equal concentric areas, as shown in Fig. 2, and placing the tube orifices at a predetermined point in each ring, both above and below the pipe center. These points must lie on concentric rings which divide the respective rings into two equal areas. The average of these individual velocities gives the average velocity of flow. Note that to obtain the average velocity by using the average deflection would be wrong, as the velocity is proportional to the square root of the deflection. The coefficient of our pitometer is 0.72. We have a 1-in. corporation cock tapped into the top of each discharge pipe. The pipes vary from 15 to 36 in. The end of the pitot tube is pulled up into the recessed nut M, which is screwed on the top of the corporation cock which is then opened and the tube pushed down into the pipe. A stuffing-box at the top of the nut M prevents leakage. By means of a pointer attached to the top of the tube, and a scale, the orifices can be placed at any desired point in the pipe, in a vertical line from the cock. As obtaining the readings of the cross-section of, say, a 30-in. pipe is a matter of half an hour, care must be taken to read the center of the pipe from time to time, to make sure that the flow remains uniform.

The foregoing may create the impression that the use of a pitot tube is a complex matter, while as a matter of fact it is simple after the necessary tables are figured out, and these do not involve more than simple algebra. The chief objection to a home-made tube is its unknown coefficient, which must be determined with some degree of accuracy to make the instrument of any value for test purposes. When checked against a weir, our tube showed a difference of 2 or 3 per cent. W. F. **Brye.**

Patterson, Calif.

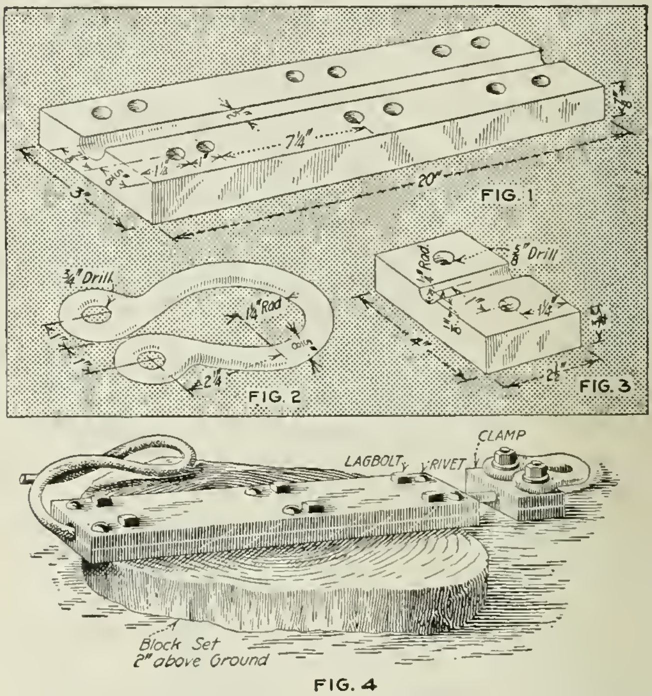
Home-Made Wire Straightener

The article, "Home-Made Wire Straighteners," in the Nov. 27, 1917, issue of *Power*, brings to mind how the straightening of about 6000 ft. of No. 0000 bare-copper wire was accomplished at one of our mines. When we received this wire, it was in bundles containing lengths of from 300 to 500 ft. The rolls were of small circumference, and in several places the wire had sharp bends in it.

At first we tried to straighten the wire by laying it on a wooden block and hammering it with wooden mallets. But this was too slow a process and I set about devising a quicker way of doing the job, the result of which was the straightener shown in the figures. This device is made of two pieces of metal of the dimensions shown in Fig. 1, riveted together and mounted on a wooden block set in the ground as in Fig. 4. The straightening was then done as follows:

One end of a cable was made straight for about two feet and pushed through the straightener; then the clamp detailed in Figs. 2 and 3 was placed on the end of the wire extending through the straightener, as in Fig. 4, and a horse used to pull the bent wire through the straightener. The straightening was then done as fast as the horse could walk. The slots in the two halves of the straightener were made on a planer, as we did not have any drill long enough to drill the hole after the two parts had been assembled. Wire of any size can be straightened by making the hole in the device to fit the wire. The corners at the end of the hole should be well rounded to prevent damaging the wire. I have never tried to use this straightener on insulated or lead-covered insulated wire, but I see no reason why it cannot be done. Thomas J. **Pascoe.**

Norway, Mich.



FIGS. 1 TO 4. PARTS AND ASSEMBLY OF WIRE STRAIGHTENER

Change of Water for Air Pump

Replying to L. F. Forseille's question, "Would change in water for air pump be good or bad," in the Nov. 20, 1917, issue of *Power*, page 703:

The change as indicated by the sketch would not be advisable and if tried would probably result in a loss of 0.5 to 1.5 in. vacuum under full-load conditions. This loss in vacuum would be caused by the warm-water injection for the air pump having a higher temperature than that corresponding to the temperature of the vacuum in the condenser. Some of the water would be evaporated, filling the space that should be filled with air from the condenser; also, the warm water coming in contact with the cooler air from the condenser would cause the air to rise in temperature and increase in volume. This would reduce the efficiency and capacity of the air pump. The air pump and condenser were operating with injection water of the same temperature, when no bad effect was noted with a 75-

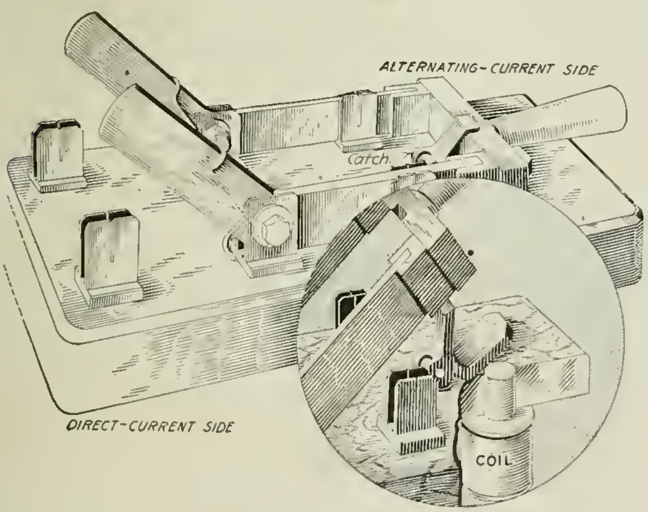
deg. F. rise in the temperature of the injection water. The trouble due to ice obstructing the flow of water through the strainer could be overcome by constructing an air-pump discharge pit. The air-pump injection-water supply would be from the discharge pit. Some arrangement must be made to supply cold makeup water, so as to keep the air-pump injection water within 2 deg. F. of the condenser injection-water temperature. Should this arrangement fail to reduce the work on the pump turbine or fail to get an ample water supply to the condenser, I would suggest that a larger set of nozzle blocks be put in the turbine to increase its capacity and do the required amount of work.

Montgomery, Ala. J. E. CRAVEN.

An Emergency Lighting Switch

Some power plants, in case of a shutdown at night, use lanterns lighted and placed in convenient positions where they can be readily secured in case of an emergency. However, there are many plants that go without any protection against being left in darkness, and others use small gas lights. The method I saw used some time ago in a substation looked to be as about as satisfactory as any for emergency lighting.

The lighting switch for the building was double-throw and of a type shown in the figure. The right-hand contacts were connected to 110-volt alternating current, and the left-hand terminals connected to 112-volt direct current coming from an auxiliary battery used for remote control of the oil switches. The lighting circuit connected to the two middle contacts. Between the studs on the alternating-current side on the back of the switchboard, a magnet coil was arranged as shown in the sectional view and connected across these studs.



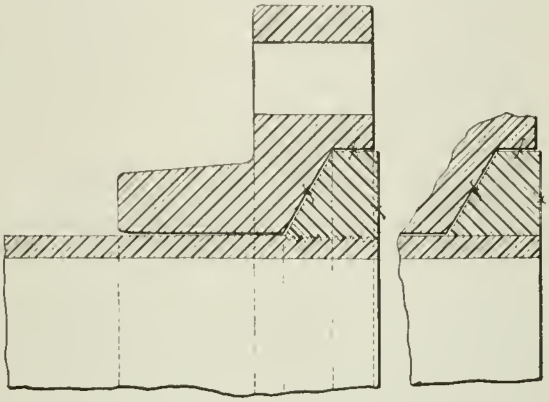
DOUBLE-POLE, DOUBLE-THROW LIGHTING SWITCH

This coil held the switch closed to the alternating-current supply under normal conditions. Springs were placed on the middle studs to throw the switch to the opposite position when released by the magnet coil. In this way, if the alternating-current source failed, the switch was thrown to the battery circuit, thus lighting the station from this source. After the plant was running all right again, the attendant would throw the lighting switch back on the alternating-current side.

New York City. D. R. HIBBS.

Combination Pipe Joint

The need of a pipe joint suitable for any pressure, which can be attached to the pipe, on the job, without expensive equipment, has long been recognized. The combination joint, two types of which are shown in the illustration, was designed by me for use on all lines requiring flanged joints. It consists in attaching a metal collar or band to the pipe by means of ordinary pipe thread, shrinking, welding or a combination of these methods; the collar or band to form the joint or gasket face, followed and held in place by a flange loose on the pipe, similar to the Van Stone type.



MEANS OF ATTACHING FLANGES TO PIPE

This joint can be attached to pipe of any material and gives a wide scope in method of construction, combining a screwed and welded, a screwed and Van Stone, or a shrunk, welded and Van Stone joint, which does not depend entirely on the weld. The joint is somewhat flexible, and the holes can be aligned by turning the loose flange; and in case of cutting a length of pipe the flanges can be used again, which is impossible with a welded flange.

The screwed and peened joint can be made in any pipe shop with ordinary tools and gives the flexibility of the Van Stone type joint. In fact, it has all the good points of the Van Stone joint and does away with the distorting, thinning or the welding on of a reinforcing facing piece to bring the pipe up to original thickness. The collars, or bands, can be machined to form male-and-female or tongue-and-groove joints. In general this joint can be used on all lines in the plant, on pipe of any material and attached to suit conditions.

Four *barefoot* men in a row, three shoveling coal into furnaces! What do you think of it? *It cannot be done.* Mr. Weil must have peculiar ideas of a boiler room of a warship, in which men go around in their bare feet. How about cleaning fires? When they pull "the backs out" and "shove the fronts back," do they put on their shoes then? Strange that a picture like this ever got past the censor for an engineering publication like *Power*. J. H. HOCKING.

The Lubrication of Steam Turbines

From papers on steam-turbine lubrication submitted by the following members of the Lubrication Engineers' Association of the Texas Company: W. M. Davis, John H. Young, Jr., H. D. Gohlman, J. M. Prewitt, H. J. Wilson, J. B. Barton, W. O. Kroenke, W. A. Edmondson, H. W. Salbador, J. T. Snow, D. L. Keys, F. J. Davis, J. A. Hansgen, W. G. Craig, G. M. Shanks, S. J. Hunt, W. H. Grose and Walter L. Foster. The article is from "Lubrication," published by the Texas Co.

THE weight of the turbine is small, compared with that of a piston engine of the same horsepower. For this reason and owing to the freedom from reciprocating motion, the foundations required for turbines are of small size and light weight, there being little vibration to be absorbed under proper conditions of aligning and balancing.

Turbine-oil consumption is more than the oil consumption for any other prime mover, the loss of oil being due chiefly to leakage and a small amount of evaporation. Since there is no internal lubrication, the steam is not contaminated with the oil and therefore the condensed steam is immediately available for boiler-feeding purposes without purification; and this re-use of condensed steam effects a large saving in the cost of feed water and in the expense of the maintenance and cleaning of boilers. Again, superheat, as used in the turbine, imposes no restrictions in the choice of lubricants. Finally, the turbine can usually be started and loaded more quickly than the piston engine.

HEAT FROM TURBINE AFFECTS BEARINGS

The rotating parts of the turbine proper are connected to and revolve with the shaft, so that the bearings that support the mainshaft are the only parts that require lubrication. These bearings are on either side of the turbine and are subjected to radiated heat from the steam passing through the turbine. Turbine lubrication is accomplished either by ring oilers or by some form of circulating system. Ring-oiling bearings are used on small types of turbines, the rings dipping into a reservoir of oil and carrying the oil to the bearings to be lubricated. This method has been found satisfactory where the bearings are adjusted so that the rings do not vibrate and are free from sharp edges that may interfere with their free play and, what is of still greater importance, where the reservoir into which the rings dip is of sufficient capacity to permit the oil to rest. Lubrication difficulties are sometimes experienced on certain types of turbines equipped with ring-oiling bearings because of the radiated heat. This affects particularly the governor bearing, which sometimes reaches a temperature of 240 deg. F. Fig. 1 shows an oil-ring bearing.

Larger types of turbines are usually lubricated with a self-contained circulating system which cools and strains the oil before forcing it back to the bearings under pressure. The oil is used over and over again, the relative size of the oil system determining how frequently the same oil is fed to the bearings. With this oiling system the highest temperature is experienced on the governor bearing, the next highest on the inside turbine bearing, the inside and the outboard generator bearing both being lower in temperature. The oil is in constant agitation, frequently with water that leaks past the packing glands, and unless the oil is a high-grade one, it will emulsify. Sufficient oil must be added from time to time to the system to maintain the oil level, making up for what is lost. A section of a typical, modern steam turbine, showing the self-contained oil-circulating system, is shown in Fig. 2. Oil from the various bearings flows by gravity into reservoir *B*, and a small rotary pump *A*, usually driven from the governor shaft, takes this oil and forces it through the cooler *C* and thence through pipes *D* to the various bearings. A spring relief valve *L* bypasses any excess oil back to the storage reservoir. In some systems, instead of using a relief valve *L*, the oil is discharged into an overhead reservoir and allowed to flow by gravity to the bearings. The turbine shown in Fig. 2 has four main bearings, *E*, *F*, *G* and *H*. These are hollow and cooled by circulating water. The oil is fed into the top of the bearing at the center and flows out at each end. It then drops down to chambers in the turbine casing and is collected by the return pipe *J* and returned to the reservoir *B*. A screen *K* is provided in the reservoir to remove large particles of solid matter. There are several places where the water finds its way into the oil, the main one being the packing gland *M* at the high-pressure end of the casing. Turbine manufacturers employ various methods for preventing steam leakage at this point, such as carbon packing held against the shaft by springs, labyrinth packing and water seals, but in spite of these precautions some steam always leaks out and travels along the shaft and, coming in contact with the water-cooled bearing at *E*, condenses and mixes with the oil. When turbines are operated on back pressure, there is also an outward leakage of steam at the gland end on the other end of the turbine. Occasionally, the cooler *C* or the hollow water-cooled bearings will develop small leaks, permitting water to get into the oil. A drain pump *P* is provided in the bottom of the reservoir *B* for drawing off the water that collects at this point, and should be drained off regularly. As the oil passes rapidly through this small tank, there is not sufficient time for complete separation of the water, especially when it is considered that the water and oil are thoroughly churned in passing through the rapidly moving bearings. Furthermore, steam-turbine bearings are usually run very hot and the cooking process through which the oil passes in coming in contact with the leaking steam and hot water makes an intimate mixture of oil and water. Taking these points into consideration, it is evident that it is necessary to provide something more than the coarse screen *K* to thoroughly purify the oil.

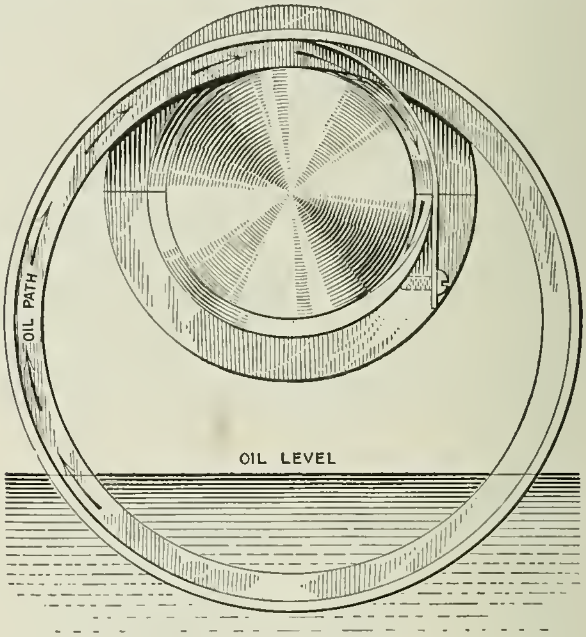

FIG. 1. OILING RING

Where a separate filtering system is used, considerably more oil is in circulation, it has more chance to rest and the water and impurities in it are removed, thus prolonging the life of the oil. One of the important advantages of a filtering system when used with the oil-circulating system is that it makes it possible to keep the cooler tubes clean. Unless a filtering system is used, the dirt that forms in the oil, due to water and foreign matter and, with some oils, to oxidation on account of high temperatures, the solids in the oil will collect in the coolest part of the turbine oil-circulating system, which is the cooler. As this dirt collects, the walls of the tubes or pipes of the cooler get a thicker coating on them and their conductivity decreases so that the full benefit of the cooling water is not realized. As this process goes on, the cooling effect in time is lost and oil will be circulated at a very high temperature. Moreover, dirt in the oil will eventually find its way to the bearings and in time, if the water that collects is not taken out, a mixture of water and oil will be fed instead of oil. Steam-turbine oiling and filtering systems may be classified as follows:

1. Continuous circulating systems in which oil used on the bearings is continuously passed through the system which filters all or part of the oil. In Fig. 3 is shown a gravity cooling and filtering system especially designed and adapted for the lubrication of steam turbines. Oil from the bearings is drained into the oil reservoir in the turbine, from which it is delivered to the filter by a pump geared to the turbine. The first filtering process precipitates the water, the oil overflowing into the filtering compartment. The speed of oil circulation is such that it would be impracticable to filter all the oil, but the heaviest and dirtiest portions are, by virtue of their greater weight, compelled to pass through the filter. The clean part escapes the filtering operation, but all the oil is compelled to pass through the cooling compartment before it reaches the vertical oil-storage tank, from which the lubricant is fed directly to the bearings. This vertical tank is placed immediately adjacent to the cooling compartment of the filter.

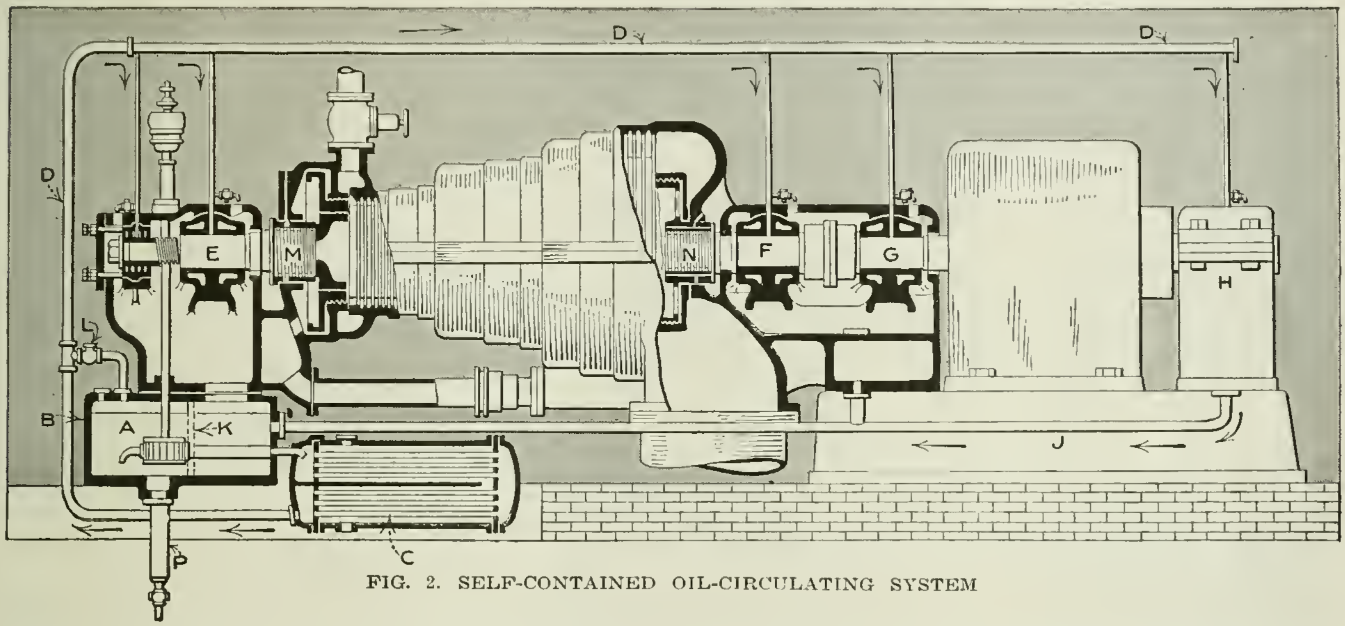

FIG. 2. SELF-CONTAINED OIL-CIRCULATING SYSTEM

2. Batch filtration, in which all the oil contained in a turbine-oiling system is removed and purified, the turbine being supplied with a fresh batch of clean oil to permit it to operate while the dirty oil is being cleaned. With this system the oil in one turbine after another can be filtered and the oil from the clean-oil compartment of the filter may be pumped into the turbine from which the dirty oil has been removed. This is the system ordinarily used where filtering systems have been introduced. In partial filtration, which was described in an article in an earlier issue of *Lubrication*,[1] part of the dirtiest oil is continuously removed from the circulating system, passed through a filter and returned to the system by a steam pump automatically controlled by the head of oil in the clean-oil compartment. In forced-feed systems which have been used in the lubrication of the Curtis vertical turbines, where the weight of the revolving parts has to be supported by hydraulic pressure, a tank large enough to contain all the oil and fitted with straining devices and cooling coils, where connected with a separate filter, is situated at a suitable level for receiving oil by gravity from all points lubricated. The oil is drawn from this tank by a pump which delivers it at a pressure about 25 per cent. in excess of that required to sustain the weight of the turbine in the step bearing. A spiral duct is situated between the source of pressure and the step bearing, and this regulates the oil supply and renders the flow more uniform. This source of pressure is also connected through a reducing valve to the upper oiling system of the machine, where a pressure of about 60 lb. is maintained. This system, which includes a storage tank partly filled with compressed air, operates the hydraulic governor mechanism and supplies oil to the upper bearings. The regulation of oil to these bearings is effected by means of adjustable baffles. Pipes from the upper bearings and from the hydraulic cylinder and release valves all discharge into a common chamber, in which the streams are visible, so that the oil distribution may always be under observation.

Previous to the adoption of turbines, it was generally believed that only fatty oils would emulsify with water, and that a mineral oil would separate from water. But it was soon discovered that the speed of the turbines was so great and the churning action so violent, that a petroleum oil that was not properly manufactured would form a permanent emulsion with any water with which it came in contact.

As an illustration of a severe case of emulsification with a paraffin oil, the case of a lead mining and milling plant in Missouri, a few years ago, may be cited. This occurred in the lubricating system of two vertical Curtis turbines fitted with a larger filter of several barrels' capacity.

The chief engineer complained that he had found it necessary to add several barrels of new oil to the system every month, and since no leaks could be found, he was at a loss as to the cause of the rapid consumption. Upon careful examination it was found that the water in the filter and settling tank was milk white, and the engineer explained that he had to draw off the water several times a day to avoid an overflow. By way of explanation he opened the drain pipe and allowed some of the water to run off. A large glass jar was filled with some of this waste water, and after it had settled there was a layer of oil found on top of the water and the water still remained a milk-white color, indicating the presence of oil still held in suspension.

With paraffin oils the peculiar conditions encountered in the bearings and the system generally may cause a partial separation of the oil and paraffin, and the subsequent contact of the oil with the cooling coils of the system results in a deposit of the paraffin, thus interfering with the proper functioning of the coils.

---

[1] Turbine Oil Filtering Systems, by Edwin M. May, "Lubrication," Vol. 3, No. 11, September, 1916.

In a previous issue of *Lubrication*[2] the conditions which have to be met by a turbine oil were stated as follows:

The demands made upon an oil in a turbine are exceedingly severe. The oil must circulate at high speed through innumerable valves, pipes and bearings, subjected first to high and then to low temperatures, and to many variations in pressure. It is thoroughly mixed with air, so much so that foam is quite frequently found on top of the oil in the settling or sump tank. Air bubbles can always be seen as the oil flows from the bearings. Frequently it must operate with a percentage of water which leaks through the stuffing-boxes or with water that leaks in from an imperfect or damaged cooler coil; or, in the case of marine installations, salt water can sometimes get into the system from overboard. At times the oil in the bearing in close proximity to the stuffing-box is actually cooked by the live steam. The steam carries with it boiler impurities or chemicals used for boiler-water treatment, and very often these chemicals in connection with the water and air cause the oil to form very bad emulsions. Any oil that has a tendency to form an emulsion is rather dangerous for use where the churning, heating and boiling with water and boiler compounds are carried on to such an extent as in a turbine lubricating system.

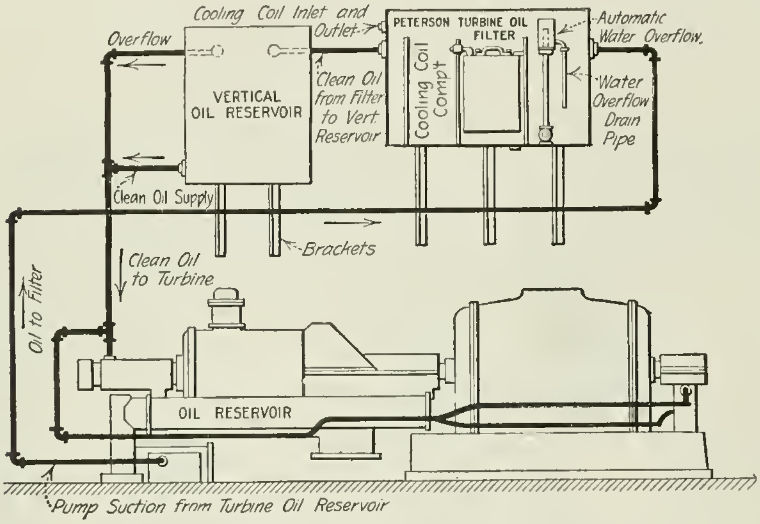

FIG. 3. TURBINE OIL CONTINUOUS COOLING AND FILTERING SYSTEM

Much damage has been done to turbines because of the tendency of certain oils to emulsify. Some oils will throw down a hard emulsion which, under conditions which prevail in the turbine, will cake in such a way as to actually stop up the pipes and oilways to the bearings. Other oils carry the water in suspension and are of such a nature that the water will drain off only with great difficulty. The best turbine oils, of course, are those that under all conditions will allow whatever water gets into them to drain off and will produce a minimum amount of emulsion, this emulsion being of such a nature that it will not form a hard deposit. The perfect oil is one of high lubricating body which will separate freely from any amount or any kind of water after it has been thoroughly agitated and even boiled and which will leave absolutely no permanent emulsion.

Next in importance is the question of viscosity. At one time the American oil manufacturers used the very lightest distillates for turbine work, the theory being that these lighter oils separated easily from water and formed less objectionable emulsions. The factor of safety, however, was exceedingly small with these light oils. The many mechanical difficulties experienced while these low-viscosity oils were in use resulted in the demand for heavier oils, until in some turbines doing very severe work, very heavy oils are now being used with complete success. The majority of turbines, however, can best be lubricated by a medium-bodied oil.

The following extract from the Terry Steam Turbine Co.'s "Instruction Book on Bearings and Lubrication" indicates the attitude of the turbine manufacturers on the subject of viscosity:

The viscosity of the oil used in any case must be suitable for the service. We are listing below oils recommended by several refiners for turbine work, in three ranges of viscosity roughly classified as light, medium and heavy. The approximate viscosity of each oil is given with its trade name. All viscosities are in seconds at 100 deg. F. by Saybolt Universal viscosimeter. These oils are tabulated for the convenience of the turbine user as being standard brands. If any oil named is found unsatisfactory for the purposes stated, please advise us for our information as soon as convenient.

a. Light oil, viscosity 130 to 200 sec., is best for turbines without reduction gears, either ring or forced feed oiling.

b. Medium oil, viscosity 200 to 350 sec., is used for turbines with reduction gears and either ring or forced oiling. It is better than a light oil for turbines subject to vibration either from within or from an external source. It will also allow slightly greater bearing clearances. Bearings may run a few degrees warmer with heavy oil than with the lighter grades.

c. Heavy oil, viscosity 350 to 500 sec., is useful in cases of bad vibration or of gears heavily loaded or causing noise. Many times gears can be successfully operated with heavy oil which would be noisy or show rapid wear with lighter oil. Heavy oil works well in turbine bearings except in places where exposure to cold sometimes makes the oil too sluggish. This applies especially to forced oiling units. When using heavy oil, more attention must be given to the oil when starting, to be sure that all rings run freely and that bearings are not flooded by the forced oiling systems.

The purpose of an oil is to form a film between the surfaces to be lubricated to minimize friction and to act as a cushion or dashpot to prevent vibration or pounding between the journal and the bearing or between adjacent gear teeth.

The lightest oil that will do this with certainty will give the lowest running temperature and usually the lowest cost per gallon. The best oil for a particular unit depends on operating conditions to a large extent, but in general the safe and economical oil to use is a grade slightly heavier than the lightest oil on which it will operate smoothly and quietly. [For an interesting article setting forth the formation, maintenance and function of the oil film in a journal bearing we suggest to the reader the following from *Power*: "The Lubrication of Bearings and Cylinders," Dec. 7, 1915. The Editors.]

INSTRUCTIONS TO ERECTING ENGINEERS

In the August, 1916, issue of *Lubrication* the turbine-oil recommendations of the Westinghouse Machine Co. and Allis-Chalmers Manufacturing Co. were given. The following is quoted from the instructions of the Westinghouse Machine Co. to their erecting engineers:

So far as mere lubrication of the turbines is concerned, almost any oil at all has lubricating properties sufficient for the bearings to run cool, so that the fact of the bearings running cool and nice is no criterion of the suitability of the oil.

A large quantity of oil is in circulation in the turbines at a temperature of from 100 to 120 deg., or thereabouts, which temperature is conducive to any chemical reaction should the necessary elements be present. It is therefore important that the oil be an absolutely pure mineral oil, free from acid. Sometimes mineral oils are adulterated with animal fats, which will in the course of time decompose, forming acids, corroding the shaft, and even eating up the bearing metals.

The following is quoted from the recommendations of the Allis-Chalmers Manufacturing Co.:

We have found it generally true in steam-turbine lubrication that, while one oil may be suitable in the majority of cases, there are from time to time, turbines that seem to require either a heavier or a lighter oil and this makes it inadvisable to issue a fixed specification governing this one class of work.

A suitable oil for the lubrication of steam turbines must have certain general characteristics which, in the order of their importance, are as follows:

The oil must be so made and of such a nature that it will separate freely from water, and that water of any nature or any temperature being agitated with the oil in any amount will not form an emulsion; even if the conditions require the oil and water to work together so that a

---

[2] "Lubrication of Steam Turbines with Recommendations of Turbine Manufacturers," by W. F. Parish, in "Lubrication," Vol. 3, No. 10, August, 1916.

mechanical mixture of the oil and water is secured, the combination must not be permanent, but upon resting and being subjected to a heating temperature of not over 175 deg. F., the water must separate. Preference should always be given to the oil separating the most quickly after being agitated with water that will be used for boiler purposes at the plant where the turbine is located. Tests should be made by shaking 50 per cent. of oil and 50 per cent. of water in a bottle or by mechanically stirring this mixture in a suitable container for, say ten minutes, and noting the separation of water after ten minutes and after twenty-four hours.

Any oil that in the above tests, or in practice will throw down a deposit, should under no conditions be used for turbine lubrication, as this deposit may, under severe conditions, interfere with the flow of the oil to the bearings.

Oil in order to meet the above conditions, must be free from acids, free from all fixed oils such as vegetable and animal oil, and should be properly refined.

The leading manufacturers of lubricating oil have introduced the practice of determining a property known as "viscosity." To determine the body, or viscosity, of an oil a standardized viscosimeter is used, by means of which the time occupied in the flow of a measured quantity of oil through a small orifice at a given temperature is measured. The Saybolt Universal viscosimeter is commonly used for this purpose by the large producers and refiners of lubricating oil in this country, the sample of oil being maintained at a temperature of 100 deg. F. and the time occupied in the flow of the measured sample of oil through a small orifice being measured in seconds. This time reading represents the relative viscosity of the oil which, in the majority of cases for steam-turbine lubrication, should be about 200 sec. at 100 deg. F. Saybolt Universal.

Should it be desired to operate the turbine with a very slight reduction in temperature of the bearings, oil as light as 150 sec. viscosity for the majority of turbines can be used. On the other hand, should the mechanical conditions require oil of heavier body, an oil as heavy as 750 sec. at 100 deg. F. Saybolt machine, can be used. All these oils, however, irrespective of the body or viscosity, should conform absolutely to the separation from moisture or water tests. All other tests, such as gravity, flash, fire and color, have no bearing whatever for this class of lubrication, but it might be well to be more explicit in regard to these particular tests. . . . .

TEMPERATURE PROPORTIONAL TO VISCOSITY OF OIL

The temperature of a bearing in a turbine working on a forced-feed system is in proportion to the viscosity or body of the oil; that is, if a very heavy-bodied oil is used, the partially resulting bearing temperature can be reduced to certain limits by the use of a lighter-bodied oil. There is a limit to the lightness of the oil, which, in the majority of cases, should not be less than 150 sec. viscosity on the Saybolt Universal machine. The temperature of a turbine bearing, however, is not a point of the greatest value in turbine lubrication. The oil heavy in viscosity has the very valuable feature of staying on the surface of the bearing after the turbine has come to rest, so that in starting, the surfaces are well lubricated. Further, heavy-bodied oils will take up bigger clearances and operate with rougher bearings and shafts without danger, whereas, under these abnormal conditions, light-bodied oils would invariably lead to trouble, as the oil would not have sufficient thickness of film to keep the high points of the surfaces apart.

The actual mechanical frictional difference, or the effect upon the mechanical efficiency of the turbine, between the use of a heavy and a light oil on a turbine having two or three bearings is infinitesimal.

Water is the main deteriorating element to the life of a turbine oil, therefore special attention should be given to keep water out of the circulating systems and out of all filters. The system should be a dry one, and daily inspection should be made to see that water is not getting in. The oil that will meet the water test can be used indefinitely in a turbine by being added to from time to time.

The following list of oils which have been used in our steam turbines and found satisfactory, is to be submitted by you, without recommendation, to any of our customers who request information regarding the kind of oil to be used in our steam turbines; the selection of the particular brand to be left to them . . . .

L. E. STROTHMAN, Manager,
Steam Turbine Department.

Follow directions. Today the direction is to save two slices of bread, an ounce of meat, an ounce of sugar, a snitch of butter. Tomorrow as conditions change there will be new directions. FOLLOW DIRECTIONS.

Engineers for the New Merchant Marine

Plans now being matured by the Recruiting Service of the United States Shipping Board reveal a system of preparation in connection with manning the new merchant marine that for thoroughness will not suffer by comparison with any known example of German efficiency.

After securing chief engineers for service on the new-type, fast cargo ships now being constructed under its direction, the board will give the men an exceptional opportunity to learn all there is to know about the engines they are to operate by sending them to the Westinghouse works, where the engines, of the geared-turbine type, are being built. Each chief will follow his own engine through the process of construction and then to the shipbuilding yard, where he will supervise its erection on board the ship, and will take charge of it as chief engineer when the vessel goes into commission.

The Board probably will first call for 125 chief engineers for this work. While on this special duty a chief will receive both pay and an adequate allowance for board. On board ship he will receive the standard pay for his grade in the merchant marine, which is high, and a bonus for war-zone voyages.

The demand thus created for the services of chief engineers is expected greatly to stimulate activity among first assistant engineers who wish to become chiefs. To assist any men of this grade, or of lower grades, to secure promotion, the Shipping Board invites them to its free schools in Marine Engineering, where they may brush up on technical matters, from a week to a month, as they may choose. There are eight of these schools, located respectively at Massachusetts Institute of Technology, Cambridge, Stevens Institute, Hoboken, The Bourse, Philadelphia, Johns Hopkins University, Baltimore, Case School of Applied Science, Cleveland, Armour Institute, Chicago, University of Washington, Seattle, and Tulane University, New Orleans.

Shadowed!

—By Darling, in the N. Y. *Tribune*

JUST ABOUT ONE MORE FALSE MOVE AND—

Convention of the N. M. E. B. A.

The National Marine Engineers' Beneficial Association held its forty-third annual convention at Baltimore, Md., during the week beginning Jan. 21, with headquarters at the Belvedere Hotel. It was necessary for the convention committee to remove the meeting from Washington, D. C., this year, owing to the lack of hotel accommodations.

There were upward of eighty delegates in attendance, representing 134 votes. The several sessions of the convention were held in the banquet hall of the hotel. Because of the large amount of business to be transacted, it was necessary to hold night sessions. At the opening meeting the delegates were addressed by James H. Preston, Mayor of Baltimore, who cordially welcomed the visitors. A charter offered by the American Federation of Labor was voted upon and accepted. At the afternoon session on Tuesday the delegates were addressed by Andrew Furuseth, International President of the Seamen's Union, who told of the labor conditions existing in the Navy and War Departments. The reading of the treasurer's report finds the organization on a sound financial basis.

On Wednesday evening, the delegates and their friends were entertained by local association No. 5 at its rooms on Baltimore St., and a pleasant evening was spent. The entertaining feature was the smoker on Thursday evening tendered to the convention by the Supplymen. There was a first-class vaudeville show, and pipes and tobacco were distributed to the auditors. On this evening the ladies were escorted to Ford's Theater.

The election of national officers resulted as follows: William S. Brown, Buffalo, N. Y., president; Thomas L. Delahunty, New York City, first vice president; John S. Fisher, Galveston, Tex., second vice president; William H. Hyman, Baltimore, Md., third vice president; George A. Grubb, Chicago, Ill., scretary; Albert L. Jones, Detroit, Mich., treasurer; William J. DuBois, Charles S. Follett, Fred H. Krueger, John S. Fisher and Charles N. Sheplar, form the executive committee. William Kelly was chosen for the board of trustees, and C. N. Vosburg was the installing officer.

The Supplymen elected its officers as follows: George F. Monroe, Garlock Packing Co., president; J. J. Cizek, the Leslie Co., vice president; Charles A. Wilhoft, New York Belting and Packing Co., secretary-treasurer. It was decided to leave the selection of the next convention city to the discretion of the executive committee.

January Meeting of the A. I. & S. E. E. and A. I. E. E. at Pittsburgh

The regular monthly meeting of the Pittsburgh Section, Association of Iron and Steel Electrical Engineers, was held at the Hotel Chatham, Pittsburgh, on Saturday evening, Jan. 18, jointly with a meeting of the local section of the American Institute of Electrical Engineers. Dinner was served before the meeting.

With Chairman C. A. Menk of the association and F. E. Wynne of the institute presiding, the meeting was opened with a paper by R. A. McCarty, engineer, Westinghouse Electric and Manufacturing Co., on "Methods of Power-Factor Correction." An abstract of this paper will appear in an early issue of *Power*.

Under the title, "A General Description of the Electrical Installation at the McDonald, Ohio, Works," B. A. Cornwell and B. W. Gilson, of the Carnegie Steel Co., presented an account of the transmission line, substation and distribution system at this new plant. Power is generated at the company's Ohio works, five miles distant, in a plant containing 18,000 kw. in gas-engine-driven 25-cycle alternators, at 6600 volts. It then passes through three 8000-kv.-a. oil-insulated self-cooled transformers and is stepped from 6600 to 44,000 volts. These transformers can carry the load on two units connected in open-delta in case one is taken out of service. The transmission line carries two three-phase circuits of No. 0000 wire on steel towers to a substation at the McDonald works, where the voltage is reduced from 44,000 to 6600, for roll and roll-train motors and motor-generator sets, and to 220 volts for other motors. The total line loss at full load is about 4 per cent.

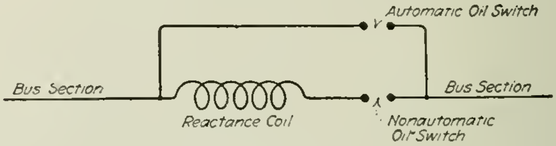
When completed, this plant will contain the following mills:

No.	Name	H P. Main Motor	Speed Variation Above or Below Synchronism Per Cent.
1	18-in. band	2,500	20
1	8-in. bar	1,000	10
1	10-in. bar	1,500	20
1	14-in. bar	2,500	20
1	12-in. hoop	2,500	20
2	10-in. hoop	3,000	20
2	8-in. hoop	2,000	10
9		15,000	

At present only the 18-in. band mill is running, and the others are scheduled for completion at the rate of one every two months.

Opening the discussion, G. C. Hecker, of the Duquesne Light Co., asked why two circuit-breakers in series are used at each end of the transmission line and what the relay arrangement is. Mr. Gilson replied that two are used for safety reasons; that each has its own equipment of current transformers, overload relays and control panel, the relay setting for one being slightly higher than the other. There is no interlocking between the circuit-breakers; one is used for normal operation, and the other is held in reserve. No reactance coils are used.

E. Friedlander, electrical superintendent of the Carnegie Works at Bessemer, suggested the advisibility of connecting a reactance across one circuit-breaker which should be the first to open, thus dividing the current to be interrupted due to a short-circuit between both breakers, instead of requiring the first one opening to rupture the entire current. On the other hand, gas-engine-driven alternators will not deliver the heavy short-circuit current, that a turbo-generator would, on account of their less inertia. He considered it better practice to install reactances between the large motors and the high-tension bus in order to prevent trouble on one motor tripping the main circuit-breakers.



Mr. Hecker said that the Duquesne Light Co. used a reactance in series with a nonautomatic oil switch between sections of its station busses; the sections were also tied by an automatic overload breaker as in the figure, so that trouble on one section would automatically cut in a reactance between that section and adjoining ones; if the trouble did not speedily clear itself, the operator would open the nonautomatic breakers and isolate the section.

Many favorable comments on the arrangement of the McDonald plant were made by those who had visited it, and it was hoped that the association might visit it in a body.

Coal Shortage in New England Still Serious

The critical shortage of coal in New England has precipitated some drastic action by Fuel Administrator Storrow. What Boston hails as a master stroke by the Fuel Administrator is the purchase with his own credit of considerable coal. After the purchase he secured priority for its shipment from Mr. McAdoo, so that this coal may now come direct to Boston and there be distributed by the Fuel Administration.

Five minutes spent in that part of the State House used by the Fuel Administration would convince even the most doubting that the Garfield order created more than havoc in and around Boston. Despite the fact that there is a considerable number in the personnel of the administration, the lobbies and halls and waiting rooms were crowded with protesting and exemption-seeking fuel users.

Mr. Storrow is convinced that there is no possibility of giving New England coal enough by means of rail transportion, as the requirements are 130,000 tons per week and half of this amount is not arriving and cannot be made to arrive over the already overloaded rails. As a matter of fact this amount is not now arriving either by rail or by water or both.

The charge is now made that during all last year there never was a shortage of boats to carry coal to New England when coal was available at the loading piers at Hampton Roads. It is further said that while the Government did take over some ships of the fleet used to carry coal to New England, those boats left were often lying idle for want of coal at the loading points. It is further reported that some of the transportation companies claim that there were times during the scarcity of coal when their tugs were hunting for barges to tow. It is quite generally conceded that inasmuch as two-thirds of the supply for New England must come by the water routes, the fleet should be increased so that a considerable more than two-thirds of the coal may come in by water and thus relieve the already seriously congested railroads. The charge is made further that great quantities of coal were sent to the West and Northwest after the lakes had frozen over and there was no means of conveying the coal by the water routes into the Northwest region. This has tied up thousands of cars loaded with coal, which have remained, as many yet remain, east of the Northwest region. Mr. Storrow has managed to head some of these cars New Englandward, but most of the coal still lies on the tracks where it was stalled weeks, perhaps months, ago, according to the latest report.

The all-rail shipment of coal ties up, it would be difficult to tell, how many cars. Because of all-rail shipment, the cars are compelled to travel many times farther than the distance between the mines and tidewater, as they do under normal conditions.

Rhode Island is in a rather serious condition, owing to the fact that the rail deliveries of coal are very low and because ice has repeatedly closed Narragansett Bay. The Navy has been busy breaking the ice and towing delayed barges to their docks.

Getting a perspective of the whole situation by viewing it here and viewing it there, one is convinced that it will be a long, long time before the rail and the water transportation systems, together with the fuel requirements and coal reserves, will again become normal.

American Society of Heating and Ventilating Engineers

The 24th annual meeting of this society, held Jan. 22, 23 and 24, at the Engineering Societies Building, 29 West 39th St., New York, proved to be one of the best in the history of the society. President J. Irvine Lyle congratulated the members on the interest that was manifested by the large attendance, even though many members living at a distance who had expected to be present, were unable on account of difficulties of traveling due to unusually severe winter weather, while a large number of the society's most active members, represented by the 38 stars of the society's service flag, had gone into the naval and military service of the country, and on the very eve of the meeting unusual demands had been made on the services of members engaged in every branch of the heating business by the extraordinary limitations placed on fuel consumption.

The Membership Committee's report showed that with all allowances, the net increase of the society's membership was 74; that would bring the membership up to about 800. A communication from the National District Heating Association stated that it had decided not to hold its meeting in June and therefore it would not be able to consolidate technical sessions with those of the A. S. H. and V. E. summer meeting of the present year. The committee working in conjunction with a committee of the Navy Department on the ventilation of battleships and submarines reported that progress had been made that will almost revolutionize the designs of some classes of ships. Committees working in conjunction with the Council of National Defense on improvement of the sanitary condition of factories engaged in the manufacture of munitions, and also the other committees that had been appointed to coöperate with various departments of national defense, reported progress. The report of the auditing committees showed that the society is in good financial condition and the recommendation was unanimously adopted that during the period of the war all members in the service of the army or navy shall have dues remitted without curtailment of privileges.

The Committee on Research Bureau recommended that a director of research work in the science of heating and ventilation should be appointed to take charge of technical investigations in behalf of the society in conjunction with a department of Government or institution of learning provided the director is selected in a manner acceptable to the society after provision is made for his salary by popular subscription providing for not less than $2500 nor more than $3600 per annum. After full discussion the subject was referred to the council with power to carry out the recommendations if found practicable.

Officers elected for the ensuing year were: President, Fred. R. Still, secretary and chief engineer of American Blower Co., Detroit, Mich.; first vice president, Walter S. Timmis, consulting engineer, New York City; second vice president, Dr. E. Vernon Hill, Department of Health, Chicago, Ill. Treasurer Homer Addams and Secretary Casin W. Obert were reëlected.

The Drying Session, Tuesday evening, Jan. 22, was occupied by an address by H. C. Gore, chemist of Department of Agriculture; a paper on "High Temperature Drying," by B. S. Harrison, and a paper by W. H. Carrier on "The Temperature of Evaporation."

Wednesday afternoon's session, devoted to fuel conservation, was enlightened by an address by Prof. L. P. Breckenridge, representing the United States Fuel Administrator. Professor Breckenridge's address was replete with interesting information on the subject of coal distribution, production and consumption, graphically illustrated by lantern slides. George W. Martin presented a paper on "Fuel Conservation," in which he stated that "the recent drastic order of Fuel Commissioner Garfield has brought to the attention of everyone the fact that serious shortage exists in the supply of coal available for domestic and power purposes."

A paper on "Economy in Fuel" was presented by Perry West, and one on "Fuel Conservation" by William M. Mackay. Wednesday afternoon's session was rounded out by a free discussion on the subject of different methods of economizing fuel and was made especially interesting by interchange of personal experiences of those present with a view of sounding the practicability of regulation of domestic fuel supply per room or per capita. The results of these comparisons showed wide variations and that it would be extremely difficult to devise a system of fuel apportionment for American residences without working serious hardship upon those whose homes could only be adapted to an average supply of fuel at great sacrifice to the owners, while to many a stringent average would be a surfeit.

"What We Do and Don't Know About Heating" was the subject of a paper by Prof. John R. Allen read at the Wednesday evening's session which will be printed in a future issue of *Power*. The report of the Committee on Code for Testing Low Pressure Boilers was received and discussed and the code was adopted as recommended in the report of the committee that was printed in the October issue of the society's Journal. The committee was continued to revise and interpret the code as may be required.

The fifth session, held Thursday morning, was given over to Furnace Heating and included the delivery of an address by D. R. Richardson, and papers: "The Engineering of Warm-Air Furnace Heating," by M. W. Ehrlich; "Answering Fuel Needs With a New Gas Heating System," by G. S. Barrows; and "Dust—Its Universality, Elimination and Conservation," by E. R. Knowles.

The professional sessions were closed Thursday afternoon by papers: "The Preservation of Hot-Water Supply Pipe," by F. N. Speller and R. G. Knowland; "The Relation of Hot-Water Service Heating to Various Types of Buildings," by H. L. Alt.; "Calculations and Analysis of a Compound

Gravity Low-Pressure Hot-Water System," by A. J. Wells; and "Measurements of Low-Pressure Steam Used for Heating the Buildings of the University of Michigan," by J. E. Emswiler.

SOCIAL ENTERTAINMENT

The programme for ladies included assemblage with the ladies' reception committee in the main lobby of the Engineering Building and luncheons and theater parties on Wednesday and Thursday, and on Thursday evening the twenty-fourth annual meeting was brought to a close by members, guests and ladies participating in a dinner and dance at the Hotel Astor.

Boston Welcomes President Main

The Boston Section of the American Society of Mechanical Engineers gave a reception to Charles T. Main, of Boston, the newly elected president of the society, on Tuesday evening, Jan. 22. The reception was held at the Engineers' Club and was preceded by a dinner, arranged by the section committee, Harry Ashton, W. G. Starkweather and F. L. Fairbanks.

Among those who spoke was John R. Freeman, of Providence, who reviewed some of the engineering achievements of Mr. Main. Mr. Freeman emphasized the Pacific Mills (textile) designed by Mr. Main, also the part the new president played in the Big Creek water-power development. Prof. Lionel S. Marks, of the Massachusetts Institute of Technology, recalled the illustrious presidents the society had had and who were New Englanders; chief among these were E. D. Leavitt, John R. Freeman and Dr. Ira N. Hollis. Prof. George C. Whipple, president of the Boston Society of Civil Engineers, spoke of Mr. Main's work in that field, and Prof. D. C. Jackson, of the Massachusetts Institute of Technology, acknowledged the indebtedness of the electrical engineers to Mr. Main for his assistance in the development of the electrical industry.

Calvin W. Rice, secretary of the American Society of Mechanical Engineers, told of the society's work in the war, claiming that considerable was yet to be done and urging upon the engineers to give their services to the Government. R. A. Hale, of the Essex Co., Lawrence, emphasized the value of the civic services rendered by Mr. Main to his home city. Desmond Fitzgerald, one of Boston's old and distinguished citizens, was most entertaining in his portrayal of Mr. Main's life, so full of experience, so simple and so accomplished.

Those in attendance then listened to W. R. Balch, war editor of the Boston *Transcript*, tell of events in Europe during the war. Mr. Balch laid particular stress upon the great social, moral and economic changes sure to come out of the war. Unfortunately he had to cut his address to a half hour on account of Fuel Administrator Storrow's order closing all public places at 10 o'clock.

Proposed Law Allows Expansion of Municipal Power Plants

The borough officials of Madison, N. J., in coöperation with neighboring municipalities, have drafted two interesting bills to be presented at the present session of the State Legislature, covering extended powers for municipal-lighting plants. These bills relate to two distinct phases of station operation, the first dealing with service combination between two or more municipal plants for greater efficiency, particularly with reference to fuel conservation, and the second to cover the sale of electric energy generated by municipal stations outside of the city or borough limits. These measures are the result of recent decisions of the Board of Public Utility Commissioners in holding that such proposed conditions of operation would make the plants subject to the jurisdiction of the board, to be considered under the head of regular public utilities.

The first-noted bill provides for the granting of authority for municipal plants in neighboring sections to coöperate and combine, where desired, for the rendering of proper service. Under this law a municipal plant would be privileged to furnish service to another community, and without falling within the domain of the state utility board in the features of bond issues, franchises, rates for light and power, etc.

As a concrete example of operation under this law the boroughs of Madison and Chatham desire to combine the service of the municipal electric plants of each municipality. In this it is proposed that the larger plant, located in Madison, furnish service for the late afternoon and night load, when the demand is heavy, in both boroughs, covering both street and private lighting, while the plant at Chatham would be employed at other periods of the day and under light-load conditions. The systems would be tied in together and the plants operated practically under one head.

By the other measure it is proposed to grant municipalities the right to sell electric current for light and power purposes outside of the municipal limits, all lines and equipment beyond the city or borough limits to be under the control of the Board of Public Utility Commissioners, but exempting the electric stations from this jurisdiction, as well as the furnishing of service strictly within the boundaries of the particular municipality.

The Madison power plant recently endeavored to supply electric energy in Chatham Township, but was compelled to discontinue service or become a regular public utility, in accordance with a ruling of the utility board. The service in this section is now being supplied by the Morris & Somerset Electric Company.

Federal Funds for Vocational Education

Recent Federal grants of money for vocational education totaling more than $240,000 have been allotted by the Federal Board for Vocational Education to eight states, each of which has complied with the terms of the Smith-Hughes law and has agreed that a sum of money equal to the amount of its grant shall be publicly raised by the state or local community. These states are Connecticut, Idaho, Illinois, New Hampshire, North Dakota, Missouri, Maryland and Vermont. The payments of Federal money are made through state boards for vocational education and are divided into three general classes—money allotted on the basis of rural population for the salaries of teachers, supervisors or directors of agricultural subjects; money allotted on the basis of urban population for the salaries of teachers of trade, home economics and industrial subjects; and money allotted on the basis of total population for the maintenance of teacher-training courses in all subjects. There are 47 states now enjoying the benefits of the Smith-Hughes act. Rhode Island has not yet accepted its provisions.—*Commerce Reports.*

Coal (?) Fifty-Five Cents a Ton!

The inventive genius of a people is said to thrive best in an atmosphere of pressing necessity. This fact possibly accounts for the amazing discovery—according to a brief newspaper note—of a method of making coal out of ashes. Making ashes out of coal is a comparatively simple and common performance. Reversing the process is remarkable, not to say miraculous. Yet it is none the less feasible, if we are to believe the statements of the secretary-treasurer of the George W. Loft Co., New York City. Says he:

> Our firm has been burning 55-cent coal for some time. We take the ashes after the furnace is done with them—just plain, ordinary ashes—and your five gallons of kerosene over about a ton of them. Then we feed the mixture into the furnace. From five gallons of oil, at 1c. a gallon, we get as much steam as we could from a ton of $8 or $10 coal.

If five gallons of kerosene, containing a total of about 700,000 B.t.u., will, when mixed with ashes, produce as much steam as 2000 lb. of coal, containing approximately 27,000,000 B.t.u., there are, in the despised ashcan, virtues of which none of us ever dreamed!

Poster Competition

Under the Auspices of the
Smoke and Dust Abatement League of Pittsburgh

1. The Smoke and Dust Abatement League desires a poster design which will express in simple form the relation of smoke abatement to fuel conservation.

2. The Committee in charge of the competition offers the following outline of the smoke abatement problem as a basis for poster ideas:

During 1917 some 500,000,000 tons of bituminous coal were consumed in the United States. Of this amount about 20 per cent., or 100,000,000 tons, were lost through imperfect combustion—the visible sign of which is black smoke.

Black smoke is an indicator of waste and inefficiency. A streamer of black smoke is the black flag of a pirate confiscating a part of the nation's resources.

Black smoke in time of peace means a great waste and a pollution of the atmosphere, which destroys building materials, retards the growth of vegetation, cuts off sunlight and daylight, prolongs fogs, is injurious to comfort and health, and is costly both to the smoke maker and to the public. In time of war it means all of that and more. Coal is a sinew of war. Coal is a food for fighters, and he who unnecessarily reduces the country's available supply curtails the nation's energy in the great industrial conflict.

The elimination of smoke requires knowledge, care, attention and some investment of money. There is no use minimizing these requirements. They are not too much to ask for the benefits resulting.

The dividends on the investment of knowledge, care and attention are self-respect, a citizen doing his duty by his fellows, and a better place in which to live and work. If the investment of money has been made with the same caution and advice as other investments, the dividends in money are nearly always sure, adequate and may be as large as speculative ventures.

3. The competition is open to all residents of the Greater Pittsburgh District.

4. The design is limited to three colors and black.

5. The size of the work is to be 15 x 24 in.

6. The seal of the league—the seal of the City of Pittsburgh with the inscription "Smoke and Dust Abatement League of Pittsburgh" encircling it—is to appear in the design. The seal is to be about three inches in diameter.

7. The designs must be handed in before noon on Feb. 16, 1918.

8. The designs are to be left at the Civic Club of Allegheny County, sixth floor, Keenan Building.

9. The name and address of contestant must be placed on the back of design.

10. The prizes are to be as follows: First prize, $50; second prize, $20; two prizes, $5; four prizes, $2.50; ten prizes, $1.

11. The first four prize-winning designs are to become the sole property of the league upon payment of the prize money. The league is to have the privilege of exhibiting all of the poster designs.

12. The judges for the competition will be announced at a later date.

13. Additional information concerning the competition may be secured from the secretary of the Smoke and Dust Abatement League, John O'Connor, Jr., Mellon Institute, University of Pittsburgh; Telephone, Schenley 897.

Committee: John O'Connor, Jr., Chairman; Mrs. Isobel A. Bowers, Miss H. Marie Dermitt, Mrs. William D. Hamilton, C. J. Taylor.

Obituary

Lieut. Gordon D. Cooke, who, prior to entering the service of the country, was a member of the field-service department of the McGraw-Hill Co., died of pneumonia at the base hospital, Fort Bliss, Tex., on Jan. 10. He was a graduate of the University of Michigan and was 24 years old.

Personal

B. J. Denman, formerly chief engineer of power plants of the Detroit Edison Co., and for the last few years vice president and general manager of the Tri-City Railway and Light Co., Davenport, Iowa, has been elected president of the company.

Miscellaneous News

A Steam Pipe, used for an exhaust through the firebox, broke and caused an explosion in the boiler room of the Alamito dairy, at Omaha, Neb., on Jan. 11, killing the fireman.

A Tube Blew Out of one of the boilers at the power house at Fayette station, Connellsville, Penn., on Jan. 13, painfully scalding five men and crippling the West Penn power system for an hour.

A Large Furnace Boiler Exploded in the subcellar of the new building occupied by Bowles lunch on Main St., Buffalo, N. Y., on Jan. 21, killing the engineer and turning the furnace room into a mass of débris. The force of the explosion shook the building and threw patrons in the lunch room into a panic. The boiler was a new one, having been installed a few weeks ago. The cause of the explosion is unknown.

Red Cross Wants Tracing Cloth—To help meet the enormous problem of securing a sufficient quantity of white goods for the manufacture of surgical dressings, the Red Cross is asking architects, manufacturers and draftsmen to contribute their discarded tracing cloth. If anyone having such material will call up one of the large laundries of his city, he will find them glad to send for such cloth as he can give them. The laundries will wash and bleach the material and forward it to its proper destination.

A Boiler Explosion at the Wishkah shingle mill, Aberdeen, Wash., on Jan. 18, killed one man, seriously injured another, and completely wrecked a portion of the plant. Both men were thrown fifty feet by the explosion, their bodies falling into the river, and bricks surrounding the boiler were thrown more than 300 yards. The concussion was felt in stores 500 yards away. A piece of the boiler weighing several hundred pounds was hurled through the air for 150 yards. The cause of the explosion is unknown.

The Navy Department Announces that men will be soon selected for aviation service. Men of suitable qualifications who report now to the Navy recruiting offices are eligible for examination for commissions and ratings. The rates of pay and duties assigned in this aviation work in the Navy will make this opportunity highly attractive to mechanical engineers and to draftsmen, mechanics and others who are experienced in gasoline-engine design or operation. Full information may be obtained at any Navy recruiting office.

Merger of Electrical Plants—The Mohawk Gas Co., understood as being controlled by General Electric Co. interests, has filed intentions with the Public Service Commission and the Schenectady County Clerk a plan to merger all plants that generate electric power from the Hudson River west to Herkimer County, which would include the Spier Falls and Schaghticoke hydro-electric plants and which would indirectly control the electric-power supply of the City of Albany and the cities and towns of Albany, Rensselaer, Fulton, Schoharie, Montgomery County and part of Herkimer County. Application has also been filed with the Public Service Commission to combine the Schenectady Illuminating Co., Schenectady Power Co. and the Mohawk Gas Co., under the name of the Mohawk Gas Co.

Power-Plant Courses in Wisconsin—The University of Wisconsin, University Extension Division, is now prepared to give, by correspondence, a course in practical hand firing, which will take up methods of making a good fire, fuel supply, tools, size of coal, effect on smoke, boiler stresses, effect of clinker, draft regulation and feed water problems, and the care of boilers. The University is having considerable success with this course, particularly in plants which are face to face with coal shortage. The following steam-engineering courses have been prepared for firemen and engineers who desire to increase their efficiency and prepare for promotion and increased earnings: Steam Boilers, Part I; Steam Boilers, Part II; Steam Engines, Part I; Steam Engines, Part II; Heat—Part I, Principles; Heat—Part II, Application, Fuel, Refrigeration, Heating and Ventilation. Those desiring further information should address the University Extension Division, University of Wisconsin, Madison, Wis.

Massachusetts Teaches Power-Plant Economics—In the hope of preventing the great wastage of fuel that occurs in steam-power plants, due to inefficient management more than to equipment or to the ability of the plant to use the fuel efficiently, the State Board of Education of the Commonwealth of Massachusetts has organized a class in power-plant economics, the first lecture being Monday evening, Feb. 4, at Room 109, State House, Boston. The idea of the classes is the dissemination of easily understood information of how to obtain the full worth of every pound of fuel used in the industry. J. A. Eames, instructor in mechanical engineering, in the Department of University Extension of the Massachusetts Institute of Technology, will give the course, which will be in the form of lectures and discussion on modern power-plant problems. The subjects include power-plant location, boiler plans, equipment, methods of firing, arrangement of heating surfaces, and specifications for the purchase of coal by contract. There is no charge for tuition, but the student is expected to buy his textbooks.

Business Items

The Liberty Manufacturing Co. has removed its offices from Susquehanna St. to the Frick Building, Pittsburgh, Penn.

The Elliott Co. has disposed of its office building on Susquehanna St., and taken offices in the Frick Building, Pittsburgh, Penn.

The Esterline Co., Indianapolis, Ind., announces the appointment of the F. R. Jennings Co., 616 Ford Building, Detroit, Mich., as its sales representative for graphic instruments for the state of Michigan. Mr. Jennings will handle the entire state for the Esterline Co., with the exception of the northern peninsula, which is taken care of by the Milwaukee office.

The National Tube Co. is sending out an interesting circular illustrating seven instances of the remarkable ductility of "National" pipe. In Biblical times seven was a number signifying completeness; the furnace in which the three Hebrew children were placed was heated sever times hotter than usual. Also in profane history we read of the Seven Wonders of the World, the Seven Wise Men of Greece, etc. Therefore, out of the many instances of the ductility of "National" pipe seven was the number appropriately chosen for illustration.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual [1]	
	Jan. 31, 1918	One Year Ago	Jan. 31, 1918	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Jan. 31, 1918	One Year Ago	Jan. 31, 1918	One Year Ago
Clearfields....	....	$3.00	....	$4.25—5.00
Cambrias and Somersets...	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b, Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual [1]	
	Jan. 31, 1918	One Year Ago	Jan. 31, 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$6.50—6.75
Buckwheat ..	4.30—5.00	2.75	5.50—6.00	6.00—6.25
Rice	3.75—3.95	2.20	4.50—5.00	4.50—5.00
Barley	3.25—3.50	1.95	4.00—4.25	3.25—3.75
Boiler	3.50—3.75	2.20	....	....

Bituminous smithing coal, $4.50—5.25 f.o.b.

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate).................	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide		Independent
	Jan. 31, 1918	One Year Ago	Jan. 31, 1918		One Year Ago
Buckwheat ...	$3.15-3.75	$2.00	$3.75	$2.90	$4.15

PROPOSED CONSTRUCTION

Ala., Russellville—The Alabama Power Co. is having plans prepared for the extension of its transmission line from here to Sheffield and Muscle Shoals. W. N. Walmsley, Birmingham, Gen. Mgr.

Conn., Norwich—City plans to install new electric equipment including a 300-kw. turbine with a 500-hp. boiler in its gas and electric plant. Estimated cost, $200,000.

Conn., Thamesville—(Norwich P. O.)—The Eastern Connecticut Power Co. is having plans prepared by H. M. Hope Eng. Co., Eng., 185 Devonshire St., Boston, for the erection of a power plant. R. W. Perkins, Treas. Noted Dec. 4 under "Norwich."

Ga., Americus—City plans to build an electric-lighting plant. J. B. Ansley, City Engr.

Ga., Savannah—City is considering a proposition made by the Savannah Lighting Co. to install electrical turbine pumps in its water department.

Kan., Chardon—City voted to issue $25,000 bonds for the erection of an electric-lighting plant.

Mich., Menominee—The Menominee Electric Manufacturing Co. will soon award the contract for the erection of four 1-story additions to its plant. Estimated cost, $60,000.

Miss., Wiggins—City plans to improve its electric-lighting and water-works system.

Mont., Redstone—City plans to rebuild its electric-lighting plant.

N. J., Camden—Warren Webster & Co. has notified the Public Utility Commissioners of an increase in its capital stock from $150,000 to $450,000; the proceeds will be used to build additions and improvements to its plant.

N. Y., Brooklyn—The Bureau of Supplies and Accounts, Navy Department, Wash., will soon receive bids for furnishing at Navy Yard, Brooklyn, under Schedule No. 1669, 12-in. desk and bracket fans; under Schedule No. 1670, 630,000 ft. incandescent lamp cord, 11,500 ft. rubber-insulated, lead-covered wire, duplex, single-conductor, rubber covered wire, 120,000 ft. rubber-insulated telephone wire and 130,000 ft. twin conductor wire; under Schedule No. 1671, leaded and armored, interior-communication cable and 145,000 ft. plain, single-conductor wire.

N. Y., Brooklyn—The Interborough Rapid Transit Co., 165 Bway., New York City, plans to build a 1 story, 50 x 100 ft. transformer station on Livonia Ave. Estimated cost, $40,000. G. H. Pegram, New York City, Ch. Engr.

N. Y., Buffalo—The Oldman Boiler Works, 38 Illinois St., is in the market for new equipment including punching machinery, blowers, motors, a 25-ton crane and riveting machinery for its boiler shop.

N. Y., New York—The Weyant Electrical Co., 111 Broad St., has increased its capital stock from $5000 to $15,000; the proceeds will be used to build additions and improvements to its plant.

Okla., Bartlesville—The Crystal Ice and Storage Co. plans to rebuild its plant which was destroyed by fire.

Okla., Bristow—City plans an election soon to vote on $25,000 bond issue for an electric-lighting plant. T. B. Gibson, City Clerk.

Okla., Prague—City plans an election to vote on a bond issue for improvements to its electric-lighting plant.

Penn., Philadelphia—The Philadelphia Electric Co. plans to build a large power house on Beach and Palmer Sts. Estimated cost, $8,000,000. A. K. Coe, Secy.

Tex., San Angelo—The San Angelo Ice and Power Co. plans to expend about $10,000 in improvements to its plant. A. L. Lair, Mgr.

Va., Suffolk—The Virginia Ry. and Power Co. plans to issue $950,000 bonds; the proceeds will be used for extensive improvements to its plant, including the erection of an electric transmission line from here to Petersburg.

Wash., Davenport—The Washington Water Power Co. plans to build a 65-mile high tension transmission line from its Long Lake plant in Lincoln Co. to a point 12 miles south of Odessa. Estimated cost, $100,000. C. F. Uhden, Spokane, Ch. Engr.

W. Va., Switchback—The Appalachian Power Co. plans to rebuild its central power plant which was recently destroyed by fire.

W. Va., Wheeling—The Beech Bottom Coal Co. plans to rebuild its power station, which was destroyed by fire. Loss, $40,000.

Wis., Beaver Dam—The Wiscinsin Power, Light and Heat Co. plans to build a transmission line here. J. D. Roberts, Supt.

Wis., Madison—The Di-Electric Manufacturing Co., incorporated with $40,000 capital stock, plans to build a plant. E. W. Smythe, Jr., Vroman Blk., and E. K. Frautschi, incorporators.

B. C., Nelson—The Swanetta Power Co., incorporated with $500,000 capital stock, plans to build a large hydro-electric plant on the Pend d'Oreille River, south of Nelson.

Ont., Stayner—J. Knox is in the market for a 30-hp. and 3-hp. 220-volt, 60-cycle, 3-phase A.C. motor.

Que., Montreal—The Canadian Pacific Telegraph Co., 4 Hospital St., is in the market for a 25-volt, 60-ampere motor generator. W. D. Neil, Supt.

Sask., Yorkton—A. M. McNicol, Box 526, is in the market for a 250-gallon vertical centrifugal submerged pump and a vertical 40-hp. A. C. 3-phase, 60 cycle, 550-volt, direct drive motor.

Prices—Materials and Supplies

These are prices to the power plant by jobbers in the larger buying centers east of the Mississippi. Elsewhere the prices will be modified by increased freight charges and by local conditions.

ELECTRICAL SUPPLIES

KNIFE SWITCHES—Following are net prices each in cities named for knife switches mounted on slate base, front connected, punched clip type, 250 volts:

	30 Amp.	60 Amp.	100 Amp.	200 Amp.
D. P. S. T. fuseless	$0.52	$0.93	$1.90	$3.42
D. P. S. T. fused	.81	1.37	2.70	5.14
D. P. D. T. fuseless	.88	1.52	3.42	5.70
D. P. D. T. fused	1.67	2.58	5.62	9.88
T. P. S. T. fuseless	.78	1.40	2.86	5.14
T. P. S. T. fused	1.22	2.05	4.18	7.70
T. P. D. T. fuseless	1.37	2.35	5.24	8.82
T. P. D. T. fused	2.68	4.13	8.99	15.80

Lots $25 and more, list.

FUSES—Following are net prices of 250-volt inclosed fuses each, in standard packages, in cities named:

0-30 amperes	$0.11¼ each	110-200 amperes	$0.90 each
31-60 amperes	.15¾ each	225-400 amperes	1.62 each
61-100 amperes	.40 each		

FUSE PLUGS (MICA CAP) PER 100

0-30 amperes.. 4c. each in standard package quantities (500)
0.30 amperes.. 5c. each for less than standard package quantities (500)

SOCKETS, B. B. FINISH—Following are net prices in cents each in standard packages:

⅛-IN. OR PENDANT CAP			⅜-IN. CAP		
Key	Keyless	Pull	Key	Keyless	Pull
22.10c.	21.00c.	42.00c.	27.30c.	26.20c.	46.20c.

Note—Less than standard package quantities, 15% off list.

CUT-OUTS—Following are net prices each in standard-package quantities:

CUT-OUTS, PLUG

S. P. M. L.	$0.11	T. P. to D. P. S. B.	$0.24

1- to 5-lb. cans	13.25	13.00	12.50	12.50	13.00	12.50

RIVETS—The following quotations are allowed for fair-sized orders from warehouse:

	New York	Cleveland	Chicago
Steel 7/16 and smaller	30%	35%	40%*
Tinned	30%	35%	40%*

*For less than keg lots the discount is 35%.

Button heads, ¾, ⅞, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:

New York	$7.00	Cleveland	$5.85	Chicago	$5.50

Coneheads, same sizes:

New York	$7.10	Cleveland	$5.95	Chicago	$5.60

FIRE BRICK—Quotations on the different kinds in the cities named are as follows, f.o.b. works:

	New York	Chicago
Silica brick, per 1000	$50.00 to 55.00	$50.00
Fire clay brick, per 1000, No. 1	45.00 to 55.00	....
Magnesite brick, per net ton	135.00 to 145.00	....
Chrome brick, per net ton	135.00	....
Deadburned magnesite brick, per net ton	85.00 to 90.00	....
Special furnace chrome brick, per net ton	60.00 to 70.00	60.00 to 80.00

Standard size fire brick, 9 x 4½ x 2½ in. The second quality is $4 to $5 cheaper per 1000.

St. Louis—High grade, $55 to $65; St. Louis grade, $40 to $50.

Birmingham—Fire clay, $25 to $30; Denver, $23, per 1000.

Chicago—Second quality, $25 per ton.

FUEL OIL—Price variable, depending upon stock. New York quotations not available owing to this fact. In Chicago and St. Louis the following prices are quoted:

	Chicago	St. Louis
Domestic light, 22-26 Baumé	5c.	5½c.
Mexican heavy, 12-14 Baumé	7c.	None

Note—There is practically no fuel oil in Chicago at present time.

SWEDISH (NORWAY) IRON—The average price per 100 lb., in ton lots, is:

	Jan. 30, 1918	One Year Ago
New York	$15.00	$8.00
Cleveland	15.30	7.50
Chicago	15.00	6.00

In coils an advance of 50c. usually is charged.

Note—Stock very scarce generally.

POLES—Prices on Western red cedar poles:

	New York	Chicago	St. Louis	Denver
6 in. by 30 ft.	$5.59	$4.94	$4.94	$4.32
7 in. by 30 ft.	7.40	6.60	6.60	5.80
7 in. by 35 ft.	10.70	9.60	9.60	8.55
8 in. by 35 ft.	12.20	10.90	10.90	9.65
7 in. by 40 ft.	12.35	11.00	11.00	9.75
8 in. by 40 ft.	13.75	12.15	12.15	10.65
8 in. by 45 ft.	18.20	16.20	16.20	14.30
8 in. by 50 ft.	21.85	19.45	19.45	17.15

10c. higher freight rates on account of double loads.

For plain pine poles, delivered New York, the price is as follows:

10-in. butts, 5-in. tops, length 20-30 ft.	$6.00
12-in. butts, 6-in. tops, length 30-40 ft.	8.50
12-in. butts, 6-in. tops, length 41-50 ft.	9.50
14-in. butts, 6-in. tops, length 51-60 ft.	17.00
14-in. butts, 6-in. tops, length 61-71 ft.	18.50

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh, basing card in effect July 2, 1917, for iron, and May 1 for steel:

Steel			Iron		
Inches	Black	Galvanized	Inches	Black	Galvanized
BUTT WELD					
¾ to 3	49%	35½%	¾ to 1½	33%	17%
LAP WELD

2	40%	28½%	2	27%	14%
2¼ to 4	43%	31½%	9 to 12	15%	3%
4½ to 6	42%	30½%	7 to 12	25%	12%
7 to 8	38%	24½%	2½ to 4	29%	17%
9 to 12	33%	19½%	4½ to 6	28%	16%

From warehouses at the places named the following discounts hold for steel pipe:

	Black		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	38%	42%	34.27%
3½ to 6 in. lap welded	18%	38%	21.27%
7 to 12 in. lap welded	10%	35%	21.27%

	Galvanized		
	New York	Chicago	St. Louis
¾ to 3 in. butt welded	22%	22%	19.27%
3½ to 6 in. lap welded	List	18%	13.27%
7 to 12 in. lap welded	List+20%	20%	6.27%

Malleable fittings, Class B and C, from New York stock sell at 5 and 5% from list prices. Cast iron, standard sizes, 34 and 5%.

BOILER TUBES—The following are the prices for carload lots f.o.b. Pittsburgh, announced Nov. 13, as agreed upon by manufacturers and the Government:

Lap Welded Steel		Charcoal Iron	
3½ to 4½ in.	34	3½ to 4½ in.	12½
2½ to 3¼ in.	24	3 to 3¼ in.	+ 5
2¼ in.	17½	2½ to 2¾ in.	+ 7½
1¾ to 2 in.	13	2 to 2¼ in.	+22½
		1¾ to 1⅞ in.	+35

Standard Commercial Seamless—Cold drawn or hot rolled:

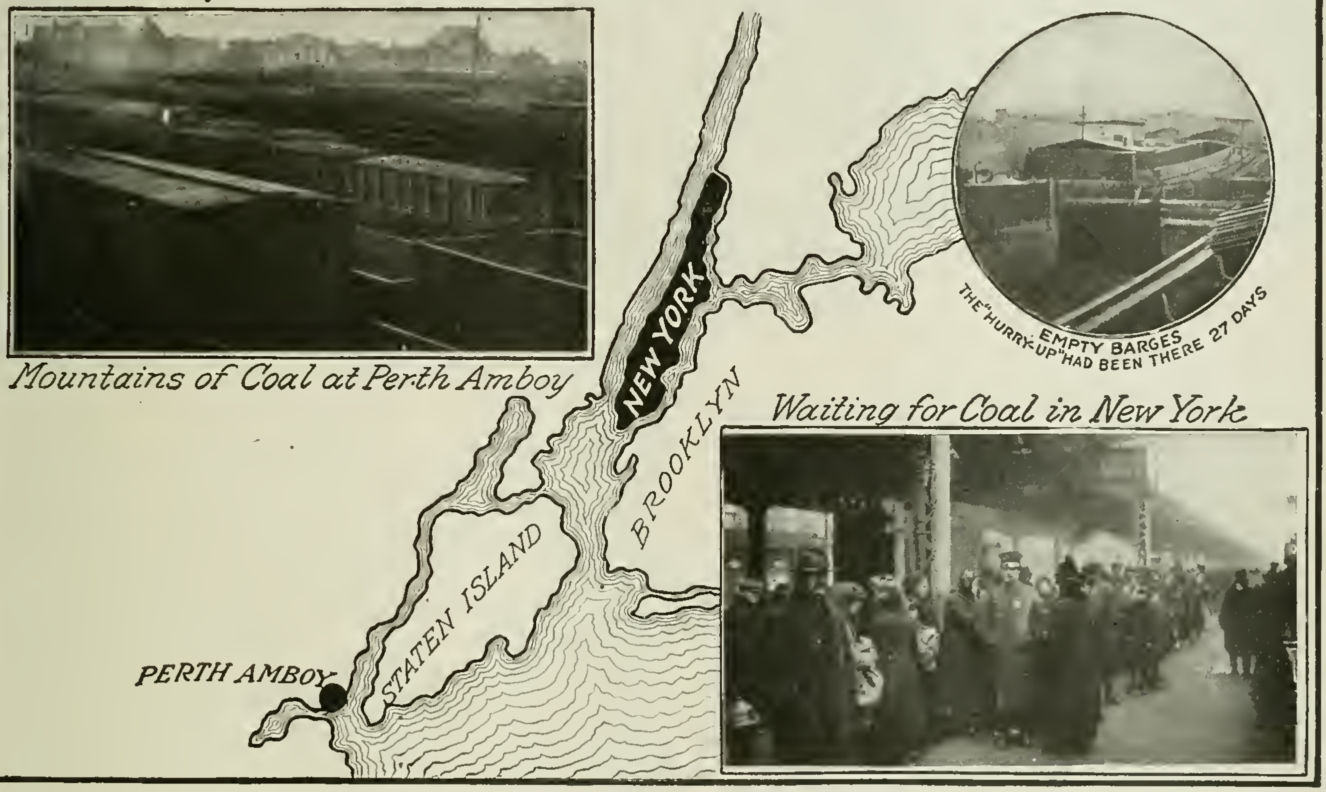
	Per Net Ton		Per Net Ton
1 in.	$340	1¾ in.	$220
1¼ in.	280	2 to 2½ in.	190
1⅜ in.	270	2¾ to 3¾ in.	180
1½ in.	220	4 in.	200
		4½ to 5 in.	220

These prices do not apply to special specifications for locomotive tubes nor to special specifications for tubes for the Navy Department, which will be subject to special negotiation.

POWER

Vol. 47 NEW YORK, FEBRUARY 12, 1918 No. 7

Why New York has no Coal



Mountains of Coal at Perth Amboy

Waiting for Coal in New York

THERE are thousands of tons of coal at the tidewater piers that supply New York City. Yet lines of people a block long wait hours to buy a hundred pounds each at 50 cents. Homes and offices go unheated and pneumonia makes new death records.

For want of barges? No, scores of them wait for days, aye weeks, at each of the piers. Ice? No, the Kill is free now. Labor shortage? No, hundreds of men are available at a fair wage.

Then with the coal, the barges, the men and a free channel, why does the city freeze?

Because the eight piers, operated by the railroads, supplying the city are unloading but 1335 cars per day average, against 1800 last year.

Because the piers are undermanned and the men paid 35 cents an hour, while almost in the shadow of the piers laborers in Government employ get twice as much.

Because the piers are worked 10 hours or so a day instead of 24 hours.

Because the thawing facilities, at one Perth Amboy pier at least, are worked at less than 10 per cent. capacity, while there are not enough facilities at others. Because this pier unloads but three cars at a time instead of a possible 28. Because it employs 26 men instead of a hundred.

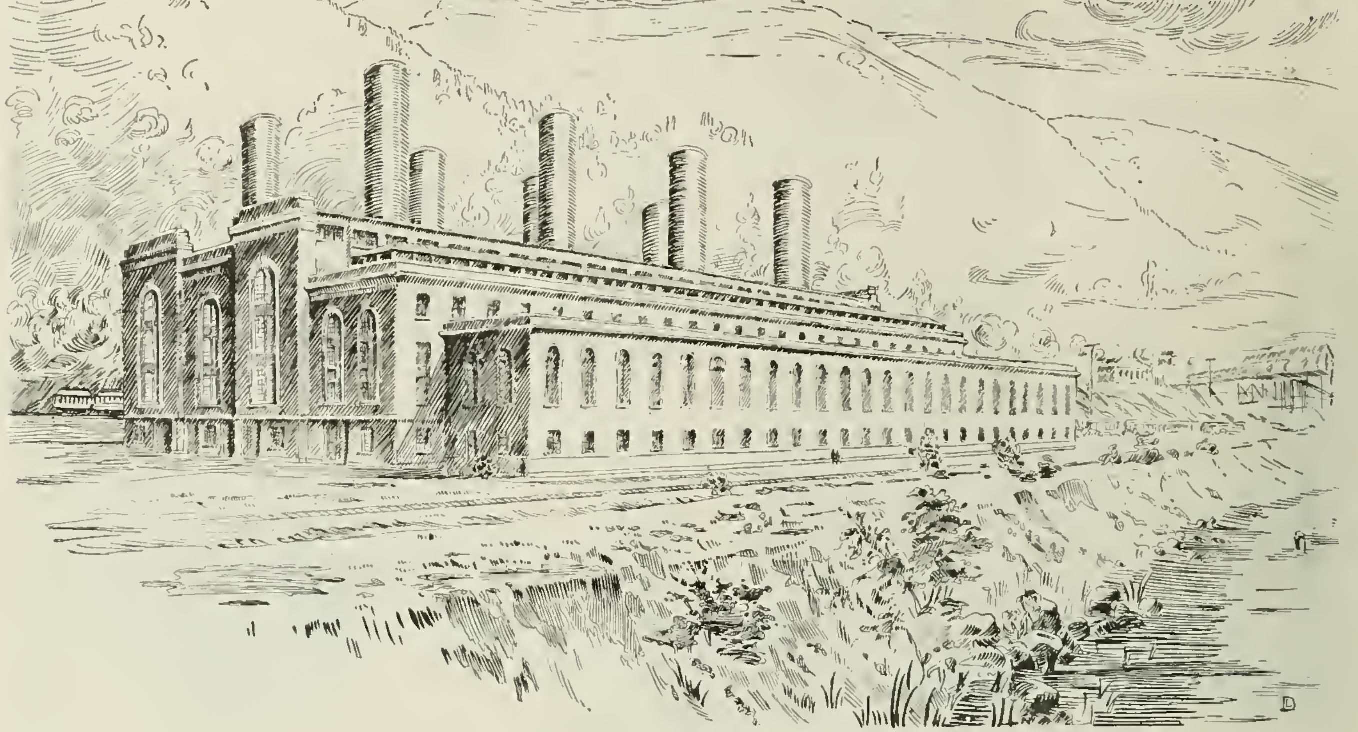
Because a gang of six men spend two days unloading one car of frozen culm.

Because, at this writing, anthracite is not pooled, causing switching and waiting of cars, decrease of coal production and astounding delay of barges.

The miners blame the railroads, who say they are through when they land the coal at tidewater; the pier management blames the shipper for delaying the arrival of his barges. Thus "the buck is passed next door."

(See editorial pages.)

THE WINDSOR POWER STATION



Features in the location, design and equipment of a huge plant located at a coal mine in West Virginia to produce bulk energy for its joint owners, the American Gas and Electric Co. and the West Penn Power Co. Commercial power was first put on the line to Canton, Ohio, Aug. 28, 1917.

WHEN it is looked upon in retrospect, the construction of the $10,000,000 Windsor (W. Va.) plant of the American Gas and Electric Co. and the West Penn Power Co. will probably be seen to mark a new epoch in the central-station industry. Far-seeing engineers and central-station executives now view it as a pioneer station; they see it as one of an interconnected group of great plants strategically located to produce large quantities of energy so cheaply that it may be economically transmitted over wide areas to serve one of the greatest industrial districts in the world. True, plants have been built at coal mines before; but this is a pioneer station in the respect that it is the first coal-burning bulk supply station of any considerable size. Before another year lapses, the station will rank among the world's largest steam plants. It is the initial step toward carrying into actual practice in a broad way what has proved to be successful on a smaller scale in the Middle West with steam and in the Far West with hydro-electric power.

As a bulk supply station the Windsor plant has an enviable situation. Being on the Ohio River, it has an adequate and dependable supply of good water. Fig. 2 is a view of the station at its present state of completion. It is being continued for the second section at the left of the illustration. It is but 2000 ft. from a coal mine that produces fuel running around 13,500 B.t.u. per lb. It is on the Pittsburgh, Wheeling & Kentucky branch of the Pennsylvania R.R. The 58 acres of real estate purchased around the plant site was not expensive. It lies between the Eastern and the Central time belts and receives, therefore, those advantages of diversity which come from serving loads thrown on systems at different times by reason of the arbitrary shifting of clocks as the meridian is passed. Moreover, it lies in what is practically the load center of the eastern Ohio, western Pennsylvania and Wheeling (W. Va.) industrial district which it will serve. This location for a large station possesses the further advantage of serving a territory in which the general run of boiler-feed water gives enough troubles to isolated plants to induce them to central-station service. This water, taken from small streams, is contaminated to a considerable extent by water from the mines. In fact, this exact site was chosen after a thorough search extending on both sides of the Ohio River from Steubenville to Wheeling.

The ultimate rating of the station as it is now laid out will be about 200,000 kw. in six units. Of the first 60,000 kw. of this rating in two machines now in operation, one 30,000-kw. unit was put into commercial service Aug. 28, supplying Canton, Ohio. Two additional units will be completed in 1918. The last two units will probably be installed shortly thereafter. For each turbine there are four boilers, each with 12,625 sq.ft. of heating surface. No. 2 unit of the two now installed is shown in Fig. 1. Each boiler is equipped with a separate economizer and induced-draft fan set over the boiler. Forced draft is also applied under the underfeed stokers. The boilers are arranged on both sides of a wide room, along the center of which is a large concrete coal pit into which fuel is delivered directly from the mine by special transfer cars. From this pit coal is delivered to individual hoppers in front of each boiler.

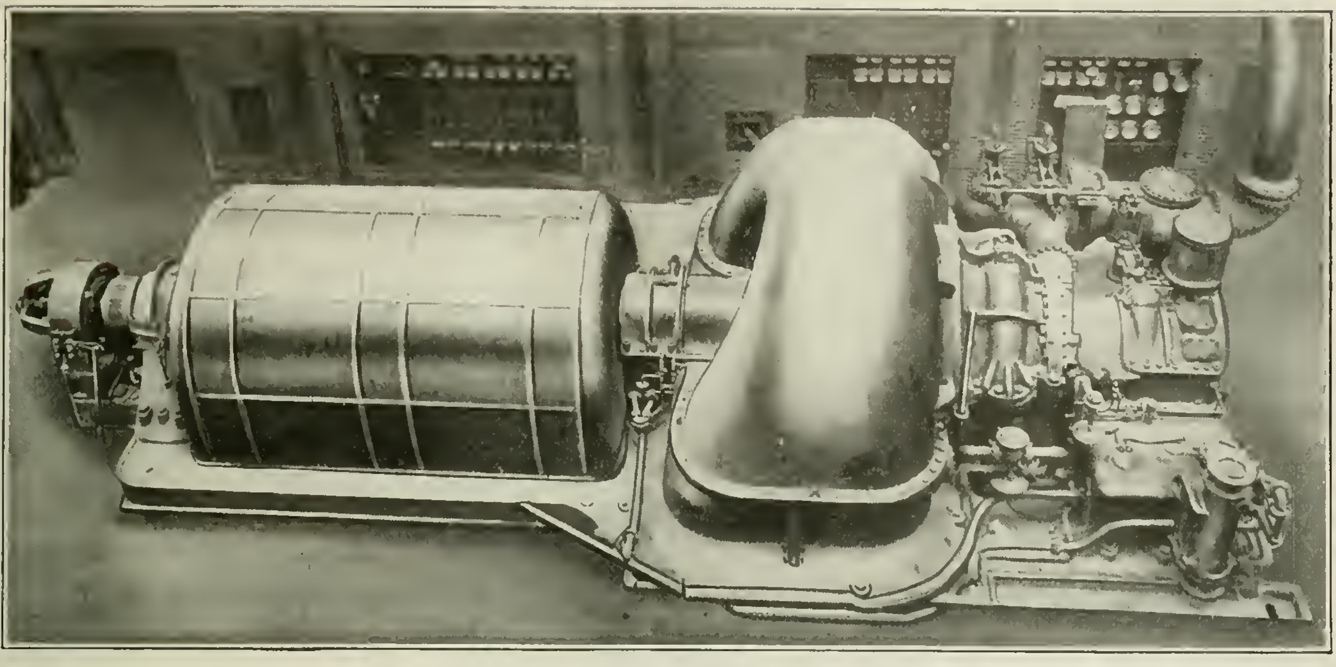


FIG. 1. ONE OF THE 30,000-KW. TURBINE UNITS

In the turbine room the machines are set in a single line with their axes parallel to the firing aisle of the boiler room. The units are grouped in pairs with the steam ends of each pair adjacent to each other and directly over a single condenser pit. This places the operating ends of each pair of units, as well as the condensing equipment of each pair, close together for convenient operation. Between each pair of turbines is a condenser pit 74 ft. deep, the walls of which form the foundation of the turbines (see Fig. 3). This pit contains two horizontal surface condensers each of 50,000 sq.ft. cooling surface, together with the auxiliary condenser motor-driven pump. Details of the condenser design, auxiliaries and intake and discharge arrangement will be published in a following article.

All tracks run into the station on trestles, owing to the elevation by the station above the high-water level of the river. Although these were costly at the outset, the space beneath them will be used for ash dumps for several years to come, providing an economical means of disposing of ashes.

The over-all dimensions of the plant with the six units completed, exclusive of the high-tension yards, will be about 295 x 280 ft. The operating floor is on one floor level, and in a plant of such size this will add greatly to the convenience of operation. Because it is necessary to radiate quantities of heat from the large units, the design has been made especially liberal as regards light and air. The radiated heat from the turbines is conducted from the generators to the basement of the boiler room, where it is taken up by the stoker fans and delivered to the furnaces.

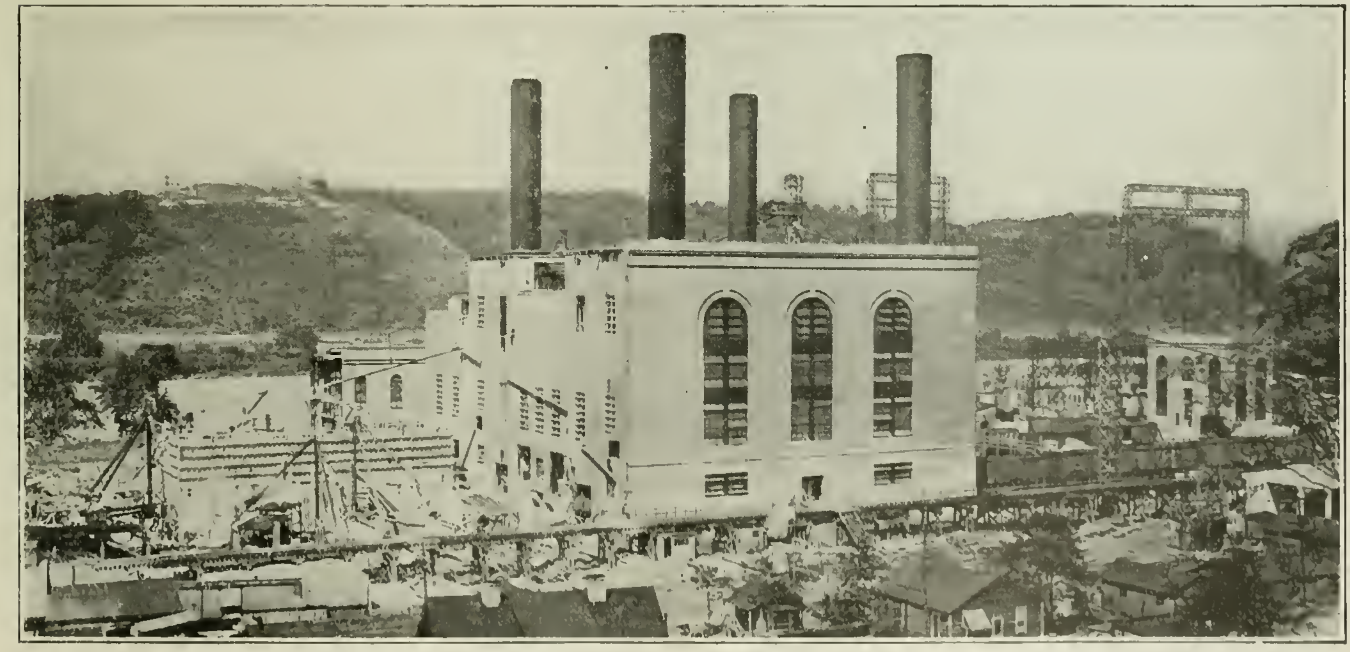

FIG. 2. COMPLETED SECTION OF THE WINDSOR POWER STATION

To get the proper perspective on the electrical end of the plant, it should be viewed in two units; namely, the low-tension or generator-voltage equipment and the high-tension equipment. Control of all low tension and high tension is centered in an operating room, between the original section of the generator room and the switchhouse. The switching of all circuits operating at the generator voltage is accomplished in this switchhouse, which is built parallel to the length of the generator room. The energy is generated at 11,000 volts, and arrangements are made so that ultimately all units in the station can operate at this potential on a ring-bus system with reactors between each two bus units.

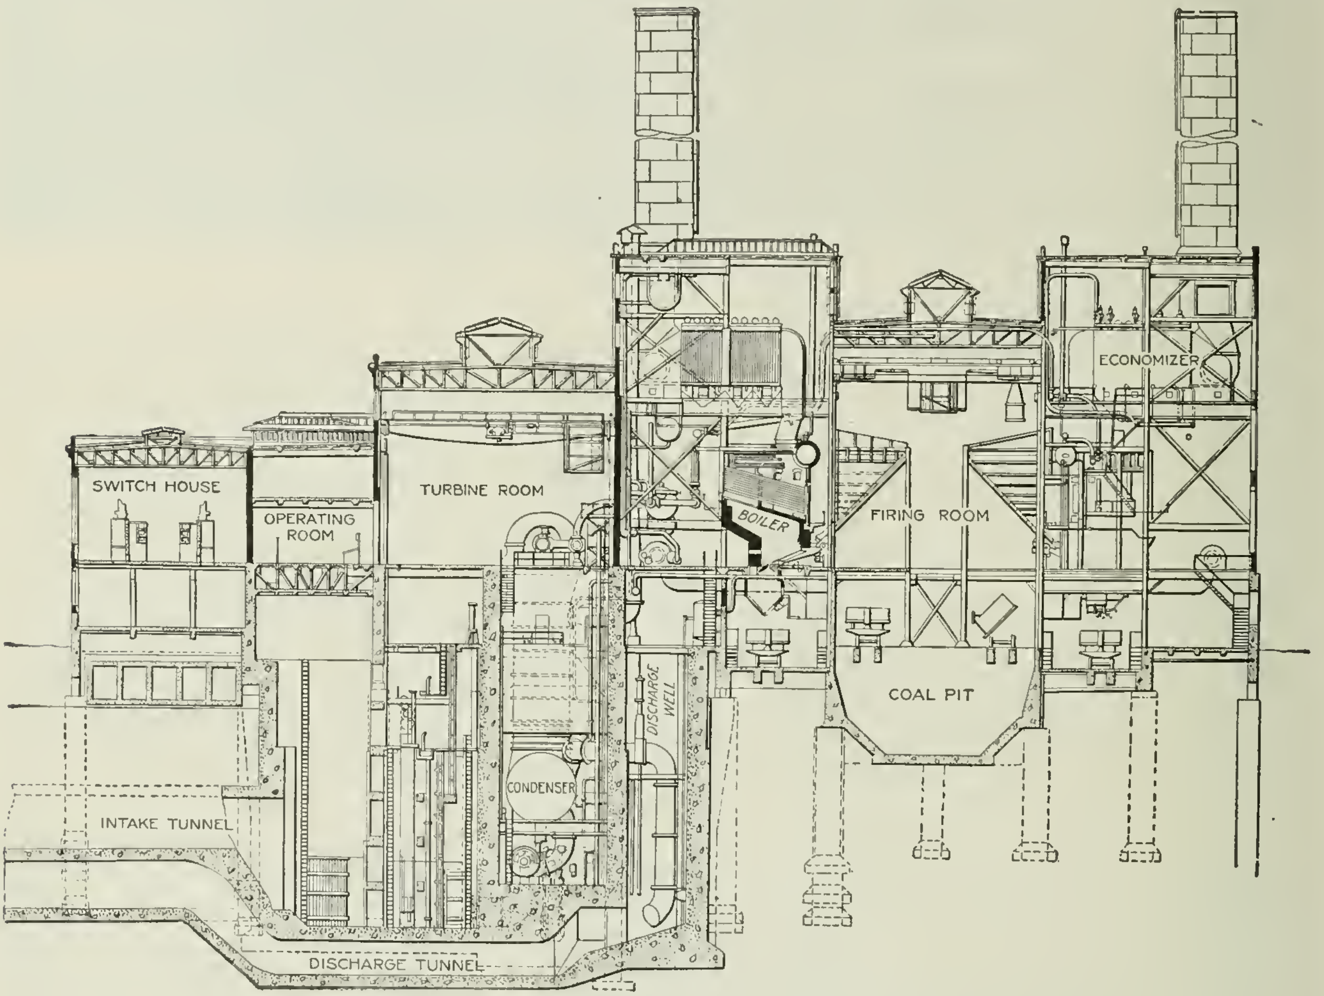

FIG. 3. ELEVATION OF THE WINDSOR PLANT

From the switchhouse the energy is distributed to two separate high-tension yards owned individually by the joint owners of the station. From these yards the electricity is transmitted to distributing companies at four different potentials.

In the building itself are several features of interest. The problem of getting a solid footing under the boiler room and switchhouse was solved by sinking caissons, but the necessity for carrying out this method under the remainder of the station was eliminated by utilizing the walls and foundations of the condenser well and intake crib to support the superstructure. The construction of the boiler-room foundations, generally speaking, consists of seven rows of concrete piers built up from depths below the surface that vary from 28 ft. to 52 ft. Still another interesting feature is the utilization of the space over the intake well for the switchboard operating room. This room is supported on 6-ft. steel trusses that span the space between the turbine-room wall and the wall of the switchhouse. The trusses do not interfere with access to the intake well, which the operating force must have for cleaning it at intervals. The 6-ft. space occupied by the trusses has proved of still further value, since it was inclosed and was used as a spacious conduit chamber for all lines leading to the switchboards in the operating room. By dividing the operating room horizontally with a floor, it has also been possible to provide offices for the chief engineer and the load dispatcher on the second floor.

The coal-handling facilities at the plant are noteworthy in several respects. Coal is secured under a long-term contract from a mine owned by the Richland Coal Co., approximately 2000 ft. from the power house. It is hauled into the station in side-dump transfer cars on a standard-gage track. All this railroad equipment is owned by the central station. It is considered important that the track is of standard gage, because in an emergency this will permit the shipment of fuel from other mines without inconvenience. At the plant the transfer cars are dumped into a concrete pit which is approximately 35 ft. wide and runs the entire length of the boiler room beneath the firing aisle. From this pit, which will hold more than 2500 tons of coal, the fuel is lifted in a 3-cu.yd. grab bucket operated from an overhead crane. After being weighed by a device on the crane, it is dropped into the individual hoppers that serve each boiler. This indirect but effective method of handling coal inside the boiler room permits a rather large quantity of fuel to be carried inside the plant without great expense, since it was possible to construct the coal pit of concrete instead of steel. A large coal-storage yard will be provided near the plant in the future.

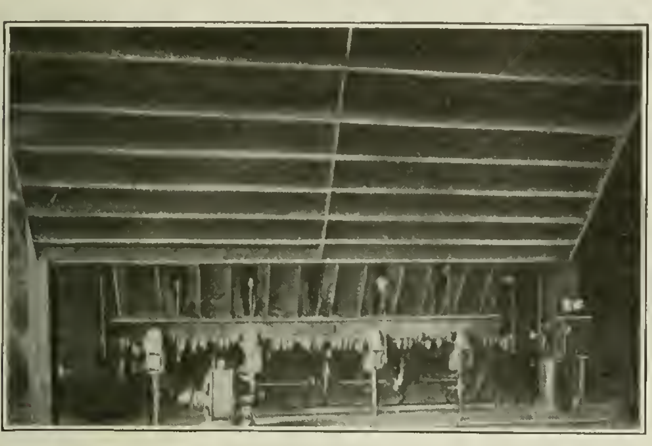

FIG. 4. FRONT VIEW OF ONE OF THE STOKERS AND COAL HOPPERS

From the hopper the coal goes by gravity to underfeed stokers with fourteen retorts per boiler (Fig. 4). These stokers are each arranged with a blast, a 100-hp. motor-driven fan being provided for each boiler. Stokers of the underfeed type were chosen for this service because they have proved efficient in burning West Virginia coal and have possibilities of high capacities.

The four boilers which serve each turbine are of the water-tube cross-drum type. Each one has 12,625 sq.ft. of heating surface and supplies steam at 250 lb. pressure and 250 deg. superheat. All settings are incased in steel to prevent air leakage. The four boilers which form a unit to serve each turbine are arranged in banks of two facing each other, on opposite sides of the firing aisle. Each bank of boilers is connected to a manifold, which in turn is connected to the steam pipe running to the turbine. Leads from the separate boilers are cross-connected. A feature of the boiler settings is the fact that the center line of the drum is 26.5 ft. above the firing-aisle floor. This arrangement provides an extra-large furnace and insures good combustion of the fuel.

As the gases leave the boiler, they are taken through economizers, Fig. 5. One 8625-sq.ft. economizer is set directly over each boiler. The economizers, which are of the high-pressure type, are arranged in two divisions, 8 tubes wide by 36 tubes long. This arrangement, it is believed, provides for the maximum heat transfer. It also allows the space between the two sections to be utilized for a bypass duct and permits a neat arrangement of the duct to the double-suction induced-draft fan. Moreover, arrangement of the economizer in this manner makes the section narrower and hence more accessible for repairs and cleaning. Dampers are provided in the uptake and are so arranged that in one position they close off the economizer and in the other position the bypass duct. From the economizer the gases pass through a 60-hp. motor-driven fan to a smoke flue which connects three boilers to a 13-ft. by 146-ft. steel stack. The gases are thus actuated by both induced and forced draft and practically a balanced draft condition is maintained over the fire. The stoker-blast equipment is designed to give a pressure equal to 6.5 in. of water. The operation of the induced-draft fans in connection with the forced draft will permit the furnaces to operate almost without pressure in the firebox. Hand regulation is employed to give proper relation of fuel and air. The ash from the furnaces is disposed of by dropping into pits, from which it can be dumped into the same transfer cars that are used for bringing coal to the plant. A plan view of the plant is shown in Fig. 6.

Because the boilers are equipped with economizers and since the large units permit the production of energy at low cost, most of the auxiliaries are motor-driven. In connection with each condensing equipment, there are two hydraulic air pumps driven by 200-hp. motors and two hotwell pumps driven by 100-hp. motors. The hydraulic air pumps are set on the gallery adjacent to the condenser, making a very short suction connection. The hotwell pumps are located on the floor of the condenser well under the condenser. The pumps, which are operated in connection with the condensing equipment, including the 50,000-gal. circulating pumps, are motor-driven.

The condensate, after passing through the condenser, is pumped through a primary heater in the upper part of the condenser up into a feed-water heater of the open type, which is set on a platform immediately over the feed pumps. These pumps and one service pump are the only steam-driven auxiliaries in the plant. There are two feed pumps on each unit, one of these pumps each on two units being motor-driven and three steam-driven.

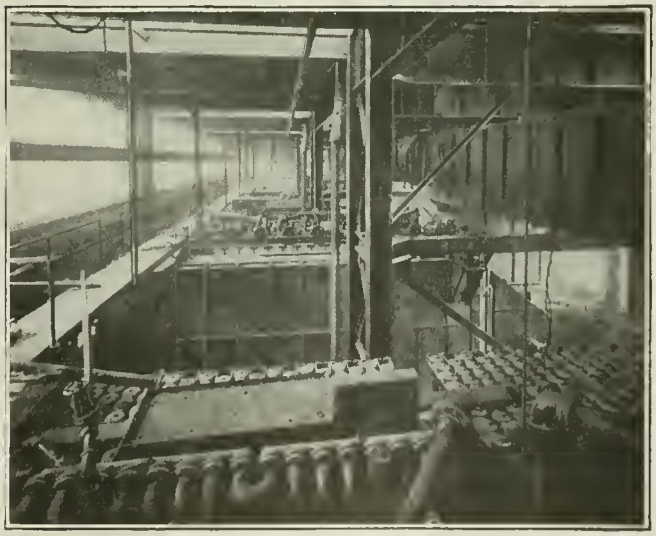

FIG. 5. VIEW ABOVE THE ECONOMIZERS

Besides those auxiliaries which are attached to each separate unit, there is one motor-driven and one steam-driven turbine service pump located in the condenser well. These units are connected to a steel service tank under the boiler-room roof. This supplies all service and all makeup water, the latter being run through a settling tank and quartz filter before going to the feed-water heaters. No other water-treating equipment is necessary. From the feed pump water is taken to the boilers through a double-feed system, the main feed being arranged to take water through the economizers and the auxiliary feed being arranged to deliver the water to the boilers direct.

On account of the fact that the condenser well is deep and a large part of the auxiliary machinery is under the condenser, an electric push-button elevator operates between the turbine-room floor and the condenser pit for the convenience of the operators.

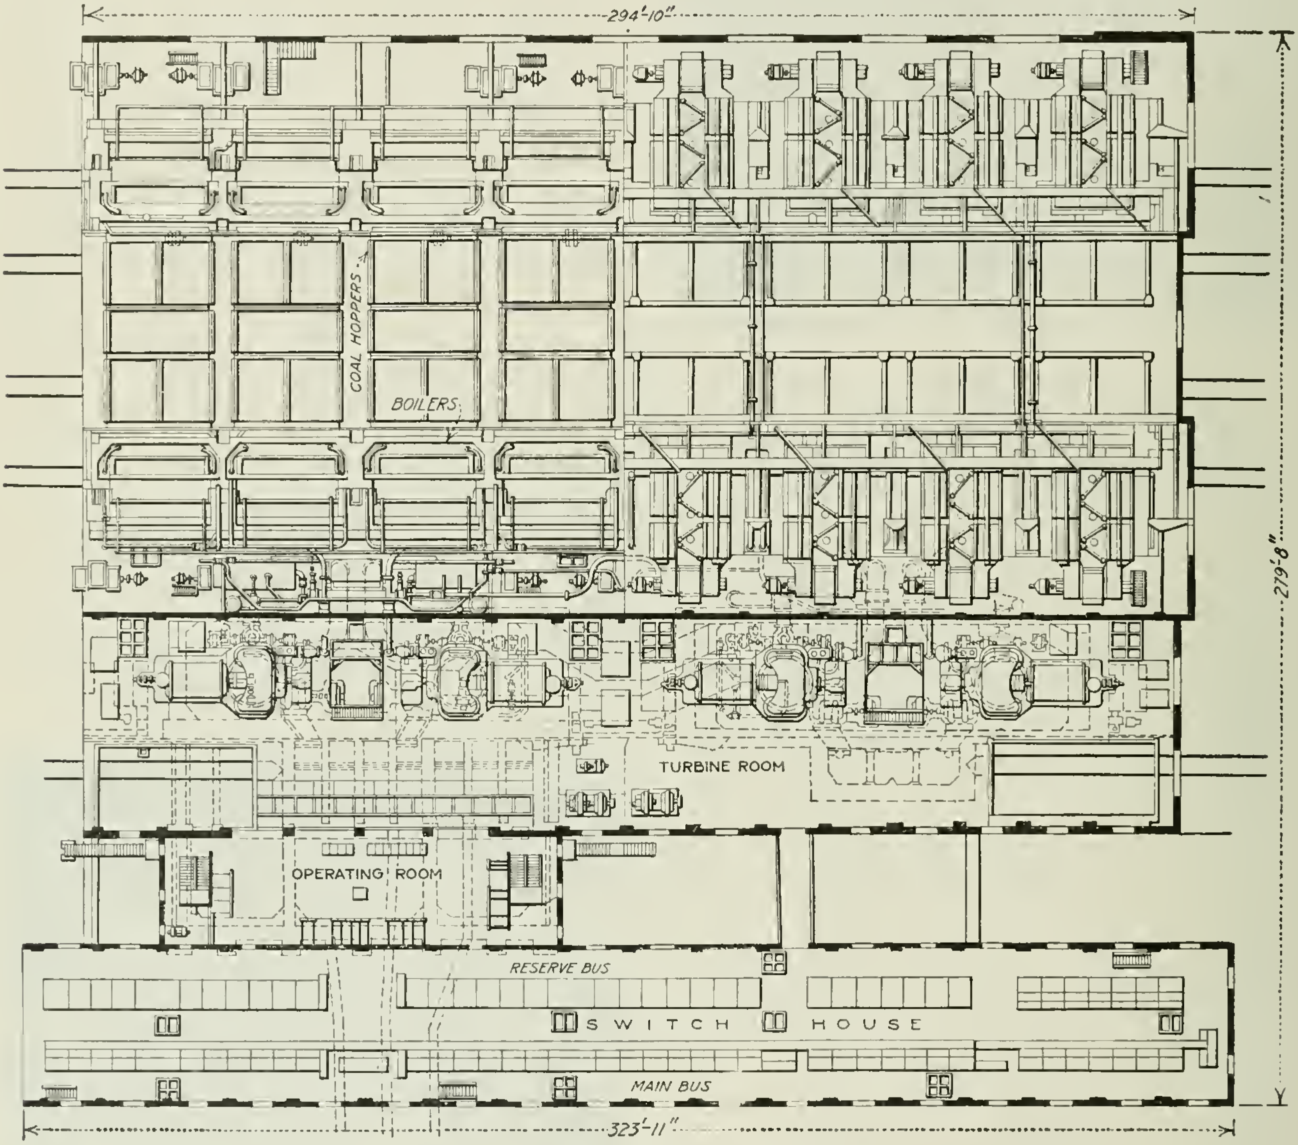

FIG. 6. PLAN VIEW OF THE STATION

In the ultimate layout the six 30,000-kw. 11,000-volt three-phase 60-cycle generators will be arranged for connection to a double-bus system composed of a main bus and a reserve bus parallel to it. The main bus will operate on the ring system, and although the reserve bus will not be operated as a ring at present, space has been left to install the ring connection at a later date if it is thought advisable. For each station unit there is a bus unit so designed as to limit the possible interchange of power between bus sections to an amount well within the guarantee of the oil-switch manufacturers. Between each bus section there is a 5 per cent. reactor, which may be placed in or taken out of the bus by opening or closing a reactor short-circuiting switch. When the generators are paralleled on the bus, they are separated by these current-limiting reactors. In this connection a unique automatic control feature has been worked out. The control circuit for operating the generator switch on the main bus and the reactor short-circuiting switch are electrically interlocked so that when the generator switch is closed, the reactor switch is open and vice versa. This prevents generators being placed on the bus without reactors between them. Provision is made for independent operation of these switches when necessary. Fig. 7 shows a single-line diagram of the main electrical connections of the plant.

The 11,000-volt cables from the turbines are arranged for connection with the 11,000-volt busses in the switch-house through either of two 2000-amp. oil switches. The busses and switch cell structures are on the turbine-room floor level. The reactors, potential transformers, current transformers, cable terminals, lightning arresters, switch gears and storage batteries which are also in the switchhouse are on the floor below. Beneath this lower floor are cable tunnels which extend out into the high-tension switchyard, carrying power cables in fiber conduit laid in concrete and control cable in iron conduit on racks.

Each turbine is provided with its own direct-connected exciter, the rating of which is sufficient to carry two generators in an emergency. The rating of each exciter is 210 kw. and the energy required for the maximum field of one machine is 140 kw. Further provision for emergency excitation was made by the installation of a 250-volt exciter bus running the full length of the station. Arrangements are made for connecting all machine exciters and all machine fields to this bus. The bus is also served by a 150-kw. motor-generator set, which was installed with the first two units. Space has also been reserved for an excitation storage battery which will be installed later. There is a voltage regulator on each machine exciter and on the separate motor-driven exciter which supplies the excitation bus.

Each unit is provided with an 1800-kv.-a. three-phase transformer to step down the potential from 1100 to 550 volts to drive the motors of its own auxiliary equipment. The electrical requirements of auxiliaries attached to one unit are about 1500 kv.-a. The stoker motors are not included in this aggregate since they are direct-current machines and are operated from 600-volt motor-generator sets which also supply cranes, hoists, automatic elevators and coal-mining equipment. Two 1800-kv.-a. station auxiliary transformers, in addition to the one attached to each turbine, are operated from the 11,000-volt bus section, and supply motors about the station which are not directly connected with any particular unit. They also supply energy for operating the motor-generator sets which furnish energy for the direct-current auxiliaries.

The feeders leaving the station can be divided roughly into four groups: The 11,000-volt feeders which supply local industries; 25,000-volt feeders which supply a network of the West Penn system; 66,000-volt feeders which supply some of the lines of the American Gas and Electric Co.; 66,000-volt feeders, which will ultimately operate at 130,000 volts and which serve a part of the West Penn system; and 130,000-volt feeders serving the longer lines of the American Gas and Electric Co.

All the feeders leaving the station are laid out on the radial system, arrangements being made for parallel operation of two lines in case of emergency. It is understood by operators, however, that radial operation is preferred and that parallel operation is an emergency measure.

Each of the 11,000-volt feeders is equipped with a 3 per cent. current-limiting reactor. These 3 per cent. reactors, like all other reactors in the plant, were not arbitrarily chosen, but were selected to limit the current that might flow into a short to a value well within the rating of the smallest oil switch in the circuit.

All of the 66,000- and 130,000-volt transformers are wound so as to be interchangeable. Furthermore, the 66,000-volt units are arranged so that they may be operated later at 130,000 volts. To provide further flexibility, arrangements have also been made for connecting together the 66,000-volt busses in the high-tension yards of the two companies.

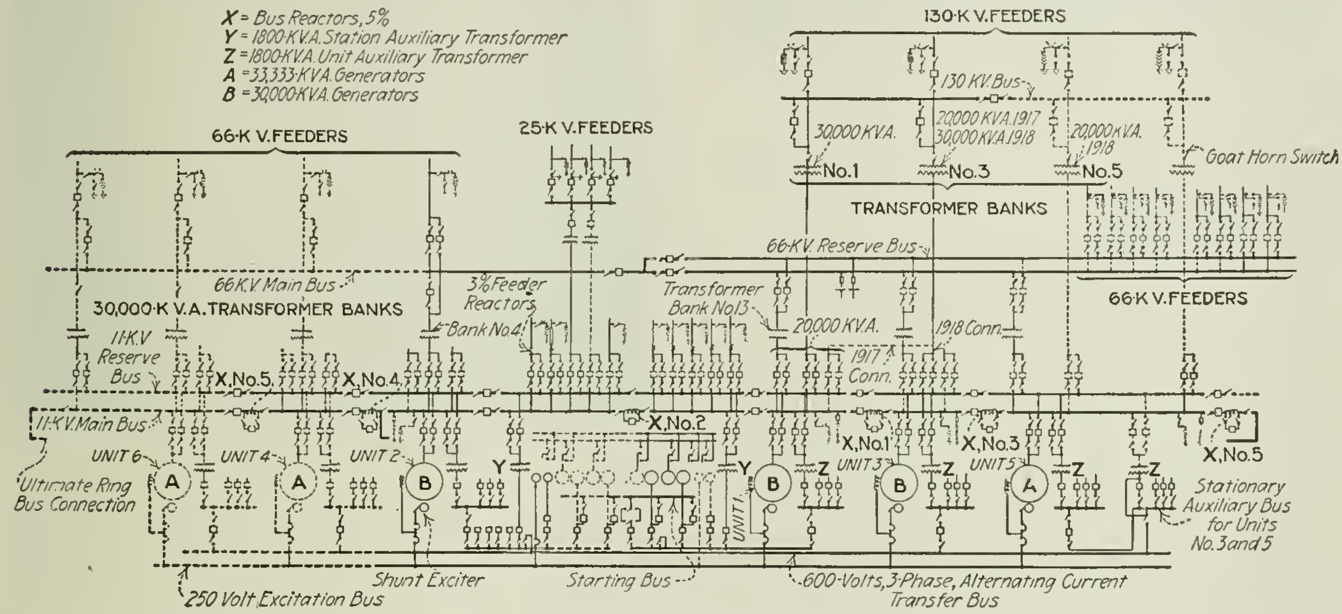

FIG. 7. SINGLE LINE DIAGRAM OF THE MAIN ELECTRICAL CONNECTIONS OF THE WINDSOR PLANT

From the main 11,000-volt bus the energy which is to be transmitted at 130,000 volts leaves the station through 30,000-kw. banks of transformers, the low-tension switches for which are located inside the station, Fig. 9. In the 130,000-volt yard the transformers are tied in solid on the low-tension side. Here a high-tension transfer bus is provided, so that the load from any outgoing 130,000-volt line can be distributed over other operating banks of transformers in case it is necessary to shut down one bank.

In the 66,000-volt yard of the American Gas and Electric Co., a double 66,000-volt bus has been provided; it is at present supplied by a bank of 20,000-kv.-a. transformers, and all outgoing 66,000-volt feeders are connected to this bus. Provision is made for the future installation of a bank of 66,000-volt transformers when the load conditions require it.

In the West Penn high-tension yard the 66,000-volt bus is normally only a transfer bus, the energy being supplied through a bank of 30,000-kv.-a. transformers. The same provision for flexible operation is made in the yard as obtains on the 130,000-volt bus of the American Gas and Electric Company.

The control of turbines, exciters and auxiliary transformers is centered on a benchboard so located in the operating room that the operator faces the turbine room while handling the equipment, Fig. 8. A glass partition between the operating room and the turbine room permits a view of practically the entire floor of the latter. Outgoing feeders are controlled from a vertical switchboard at the opposite side of the room from the benchboard. Voltage regulators and curve-drawing instruments are located on pedestals at the center of the room. The 600-volt direct-current board and the watt-hour meter board are at opposite ends of the operating room. This arrangement places the switchboards requiring the most attention at the most convenient location for the operator. It was also thought advisable to place the battery-charging equipment and panels in an alcove off the operating room, where they are readily accessible to the switchboard operators. One of the unusual features in this room is a provision for reading the temperatures of transformers in the high-tension yard and the temperatures of important parts of the 30,000-kw. generators. Alarm bells and lamps are also placed here to warn operators of any interruption in the flow of cooling water to the high-tension transformers.

FIG. 8. PARTIAL VIEW OF THE OPERATING ROOM

The 11,000-, 25,000-, 66,000- and 130,000-volt feeders are all equipped with induction-type inverse time-limit relays. The transformers are protected by definite time-limit relays. The 25,000- and 66,000-volt relays are given a minimum setting of two seconds. The 130,000-volt relays are set for three seconds. The transformer relays have a minimum setting of three seconds. The 11,000-volt feeders will supply only local territory.

The design and construction of the station, including the high-tension yard of the West Penn Power Co., were carried out by Sargent & Lundy, consulting engineers, Chicago. The high-tension yard of the American Gas and Electric Co. was handled by the Electric Bond and Share Co. The subcontracts for the building foundations, the high-tension yard foundations and the railroad foundations were all awarded to the Foundation Company of America. The Riverside Bridge Co. was awarded the contract for the steel.

FIG. 9. A BATTERY OF OIL SWITCHES

PRINCIPAL EQUIPMENT OF THE PRESENT WINDSOR, W. VA., POWER PLANT

No.	Equipment	Kind	Size	Use	Operating Conditions	Maker
2	Turbines	Steam, horizontal	30,000-kw., 80 per cent. power factor	Main generators	11,000-volt, 3-phase, 60-cycle, 1,800 r.p.m., 230 lb. steam, 200 deg. superheat	General Electric Co.
8	Boilers	B. & W. water-tube	12,625 sq ft. heating surface	Main steam generators	250 lb. pressure, 250 deg. superheat	Babcock & Wilcox Co.
8	Cleaners	Soot		Boiler tubes	With steam pressure	Diamond Power Specialty Co.
8	Stokers	Front inclined underfeed	14-retort	Boiler furnaces	Motor-driven, silent-chain drive	Westinghouse Elec. & Mfg. Co.
8	Motors	Direct-current	35-kw	Driving stokers	600-volt d.c., variable-speed	Westinghouse Elec. & Mfg. Co.
8	Economizers	High-pressure	8,256 sq.ft. heating-surface	One with each boiler	Placed above the boilers	B. F. Sturtevant Co.
8	Fans	Multivane, double-suction		Induced draft	290 r.p.m., placed above boilers	B. F. Sturtevant Co.
8	Motors	Induction	60-hp	Driving induced-draft fans.	290 r.p.m., 500 volts, 3-phase, 60-cycle.	Westinghouse Elec. & Mfg. Co.
8	Fans	Conodial, double-suction	3,500 lb. air per min.	Forced draft	Placed back of boilers, motor-driven	Buffalo Forge Co.
8	Motors	Induction	100-hp.	Driving forced-draft fans.	500 volts, 3-phase, 60-cycle	Westinghouse Elec. & Mfg. Co.
4	Stacks	Steel, brick-lined	150 ft. high. 13½ ft dia	Three boilers per stack	With forced and induced draft.	
2	Condensers	Leblanc, surface	50,000 sq.ft	With main turbines	29.2 in. vacuum expected with 75-deg. water	Westinghouse Electric & Mfg. Co.
2	Pumps	Double-runner	50,000 gal. per min	Circulating water to condensers	350 r.p.m., motor-driven	Worthington Pump & Machinery Co
2	Motors	Induction	600-hp.	Driving circulating pump.	350 r.p.m., 550-volt, 3-phase, 60-cycle	Westinghouse Elec. & Mfg. Co.
2	Heaters	Open		Feed-water heating	Takes water from primary heater	Warren Webster & Co.
4	Pumps	Turbine	6-in	Boiler feed	One motor, three turbine-driven	Worthington Pump & Machinery Co.
1	Motor	Induction	300-hp	Drives 6-in. boiler-feed pump	1,750 r.p.m., 500-volt, 3-phase, 60-cycle	Westinghouse Elec. & Mfg. Co.
3	Turbines	Horizontal	300-hp	Drives 6-in. boiler feed pumps	Direct-connected	Westinghouse Elec. & Mfg. Co.
2	Pumps	Turbine		Station service and makeup water	One motor, one turbine-driven.	Worthington Pump & Machinery Co.
	Screens	Revolving		Condenser intake	Continuously	Chain Belt Co.
	Cranes, traveling, for turbine and boiler rooms					Whiting Foundry and Machinery Co.
	Oiling system					Richardson-Phenix Co.
	Equipment for American Gas & Electric Co.'s high-tension yard					General Electric Co.
	Equipment for West Penn. Power Co.'s high tension yard					Westinghouse Elec. & Mfg. Co.

Effect of the War on Engineering Education

By C. R. Mann

The engineer, not the banker, the real power behind the throne. He is vitally involved in the control of credit, in the interpretation of the daily news and in the organization of industry and commerce. There must be closer coöperation between school and industry. The war has revealed a profounder appraisement of human values and costs and has hastened the transformation of the individualistic man into a community man willing to do his best for the common welfare. The day of the real industrial university is at hand.

THREE years ago most of us thought that a world war could not last long because, however much kings and kaisers might wish to continue, the banker would stop it. But the financiers have not come up to our expectations in this matter, and we have therefore been compelled, unwillingly perhaps, to recognize that money is not the ultimate measure of national strength. National credit is the result and not the cause of intelligent industrial production; the engineer, not the banker, is the real power behind the throne.

This fundamental fact now seems so simple and self-evident that it is rather hard to remember the time when we thought otherwise. But though the rugged outlines of this fact are now sharply silhouetted against the ruddy dawn of the new age, the details of its meaning are but dimly discernible through the haze of speculation over the significance of the struggle. Naturally, the engineer is intensely interested in the development of the details of the picture, for on him devolves the duty of interpreting the coming conceptions in terms of materials and organizations of men. And if education makes men, engineering education must be the first to feel the thrill of the dawning day.

Three Elements Can Be Perceived

Three elements in the picture can now be plainly perceived. These indicate that the engineer is from hence forth vitally involved in the control of credit, in the interpretation of the daily news, and in the organization of industry and commerce to make goods cheap and men dear.

In performing the first of these new functions the engineer becomes the partner of the banker to determine which projects are worthy of financial support and which not. As the engineering spirit is more and more infused into this dispensing of credit, public service rather than excess profit becomes the inspiration for enterprise; intelligence in production becomes the best security for loans; ability to deliver the goods becomes the sure basis of financial success; and the control of tools gradually passes from the hands of those who own them legally into the hands of those who can use them effectively.

Newspapers and periodicals already sense the expansion of the engineering spirit in the struggle to make the nation strong. The distribution of wheat, the supply of sugar, the transportation of coal and the price of bread are now subjects that occupy an amount of space in the daily press that only a Thaw trial could formerly command. The public has never before realized how vital and how interesting factories, freight cars, warehouses, terminals, trucks and ships really are. Some faint conception of the necessity of organization for the common project of liberating life by winning the war seems to be taking shape; while an impelling desire to serve and to subordinate personal preferences to community interests appears to be dimly developing. These faint feelings of fraternity may grow into driving impulses if editors continue to extol engineering enterprise rather than private profit in their interpretations of the daily news.

Engineers Have Organized To Build Up Business

In many communities chambers of commerce or groups of engineers have organized to build up business and boom the town. Through their efforts living conditions have been improved and many a city is being made a better place for homes. But the progress has always been hampered by the vested rights of individuals and of corporations, so that none has yet dared to envisage an entire community as a single working plant for the purpose of organizing it for the most intelligent production of human wealth. This can now be done. The war is opening many hitherto blind eyes to see that each gains more than he loses when he merges his strength with the might of all in an organization that is constructed for the purpose of releasing creative energy by giving each the work he is best qualified to do.

The time has come for such an organization in every community and every state, because the Federal Government is struggling to shape the nation into an organization of this type. Only so may the nation be strong; only so many communities add their utmost to the nation's strength. The responsibility for this work must finally be shouldered by engineers who are both masters of the mechanic arts and molders of men.

For many years this country has been drifting toward the realization of these requirements. The war has but accelerated the process and precipitated conclusions that were bound to come, otherwise men trained by experience to meet the present crisis could not now be found. Continuity demands that the same conclusions remain valid long after the war is ended. Therefore, engineering schools will render service in proportion as they grasp the implications of these conclusions and express them effectively in the daily work of instruction.

Closer Coöperation Between School and Industry

The possible conclusions for engineering education are many and complex, but two stand out in bold relief; namely, there must be closer coöperation between school and industry, and there must be more attention to the appraisement of values and costs.

The essential feature of the coöperation with industry is not the skill, the knowledge of workmen, or the feel of the machines which the student acquires from shop experience. Important as these are, they cannot compete with the spirt of investigation which must develop if the coöperation between school and industry is real and vital. There are thousands of unsolved problems in even such rough shopwork as freshmen are permitted to do. The boy should be trained to discover these unsolved problems and to bring them back to school for discussion and solution. By making shopwork in industrial plants the source of problems for solution in school, and by relating the class and the laboratory work in some degree to the problems raised, conditions most favorable to the self-development of the student may be realized. As he progresses, the problems become more and more intricate; until in his last year, if he has shown real engineering ability, he may be assigned as helper in industrial research, either at the plant or in the school laboratories. After such a training in defining and solving problems, closely coördinated with instruction in science and drill in mathematics, he should be able on graduation to take a responsible position without serving several years as an apprentice as is usual under present conditions.

To the faculty this type of coöperation with industry brings incentives for creative work in production and in education. For coöperation makes the school the source of solutions of industrial problems, not only with respect to the technique of manufacture, but also concerning the correlation of the community's productive processes with the training of its citizens as intelligent workers. Hitherto manufacturing companies have stood aloof and regarded one another with suspicion—and the Federal Trade Commission discovered that 200,000 of them are not paying expenses; but now they are ready to coöperate. Similarly in education, many manufacturers are supporting corporation schools to train their own help, while more than half the children in the entire country quit school at the sixth grade without being trained to earn a living; but they too are now ready to coöperate. If the men who are teaching in engineering schools rise to the responsibility and organize for the systematic study of community production, they could soon create a true university, with its feet firmly planted in industry and its soul consecrated to the task of utilizing science and literature to liberate the creative energies of men.

Appraisement of Values and Costs

While close coöperation between school and industry gives that practical experience which is essential for mastery of the mechanic arts, it is not in itself sufficient to enable the schools to meet adequately the fundamental requirements of engineering in the new epoch. The Germans are technically well trained in the mechanic arts, yet they are but brutally strong. In order to strengthen the nation by infusing the engineering spirit in the control of credit, in the interpretation of the daily news and in the organization of industry for the production of human wealth, the engineer must have sound judgment in the appraisement of values and costs. This requires not only an understanding of finance and the meaning of money, but also a sympathetic appreciation of the things humanity holds to be most worth while. Even a practical project like building a bridge is ultimately controlled by some man's decision that the resulting value is worth the cost; and this decision is more difficult and subtle when it concerns profoundly the production of human wealth and the appraisement of human values and costs. The engineer is too often obliged to be only the employee of the bank, the corporation or the state commission, because he believed that engineering is wholly a matter of technical skill; when control in this, as in everything else, is really vested in the decision of the question whether the game is worth the candle.

The training in the appraisement of values and costs does not require the addition of formal courses for that purpose, but rather the injection of this point of view into every branch of school work. For example, experiments in chemistry need not always be of the type, "Analyze this baking powder." The project, "Make baking powder and find out if it is cheaper and better than any you can buy," is vastly more effective as a training exercise. Presented as a personal effort to appraise the human values and costs in life's experiences, literature fascinates engineering students. Economics delights them when it is a critique of proposed solutions of the social problems defined by their daily coöperation with labor. Such exercises also foster the development of those homely virtues which always make the working people the bulwark of a nation's strength—the sense of justice, feelings of neighborly kindliness, devotion to right and respect for God and man.

Opportunity of the Industrial University

Thus because the war has revealed a profounder appraisement of human values and costs, and because the war has hastened the transformation of the individualistic man, selfishly seeking his own personal profit, into a community man willing to do his best for the common welfare, the ideal that was set for the engineering schools in the passage of the Morrill Act in 1862 may now be achieved. For many of the first schools founded under that act were called "Industrial Universities"; but they soon dropped the "industrial" from their titles, fearing lest they lose caste in academic councils. But now, if they gladly grasp the opportunity opening before them, they will claim with pride their abandoned surname and proceed to demonstrate that the engineer, the creator of a new earth, is also the prophet of a profounder philosophy of life.

Carbon-Monoxide Gas Poisoning

Breathing of furnace gas, smoke in burning buildings, the "afterdamp" of explosions of coal dust, etc., has caused many deaths due to poisoning by carbon monoxide. How this kills is described in the Journal of the American Medical Association.

Carbon monoxide has an avidity for hemoglobin, the red coloring matter of the blood, with which it forms the same combination as does oxygen, only 250 times as powerful.

It is, however, a misapprehension to suppose that this combination is permanent. A man brought out to the fresh air, or, better still, to whom air mixed with oxygen can be administered, will generally recover if exposure is within the following limits.

As a rough estimate, it may be stated that usually a man will die who has breathed 0.2 per cent. of carbon monoxide mixed with air which is in other respects normal, for four or five hours, or 0.4 per cent. for one hour. With from 2 to 5 per cent. of carbon monoxide death follows almost as quickly as in drowning.

The Electrical Study Course—Commutator Construction

The construction, methods of insulating and different materials used for insulating commutators for direct-current machines are described.

In a previous lesson it was shown that if a single coil is connected to rings R_1 and R_2, as in Fig. 1, and revolves between the poles of a magnet as indicated, an alternating current would be caused to flow in the external circuit *C*. It was also shown that this alternating current could be changed into a current that flows in one direction—that is, a direct current—by connecting the ends of the coil to a divided ring S_1 and S_2, as in Fig. 2. This divided ring represents the simplest form of what is called a commutator on a direct-current machine. Fig. 2 also represents the simplest form of an armature, one that has only one coil revolving in a two-pole field. In the commercial type of direct-current generators a large number of coils, depending upon the size of the machine, are arranged on the armature and connected to a commutator.

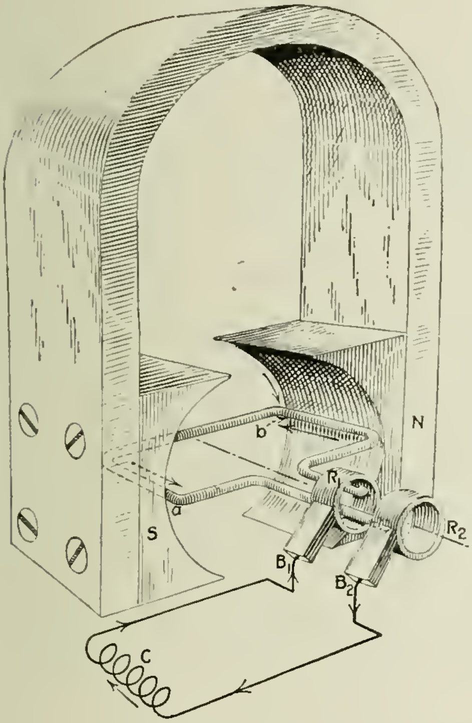

FIG. 1. ONE-COIL ALTERNATING-CURRENT GENERATOR

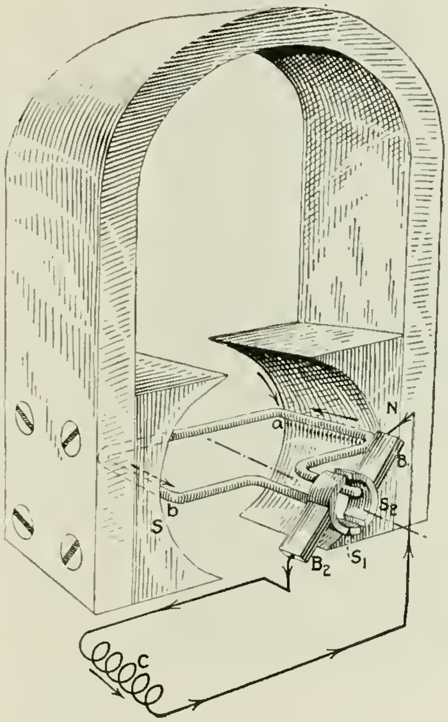

FIG. 2. ONE-COIL DIRECT-CURRENT GENERATOR

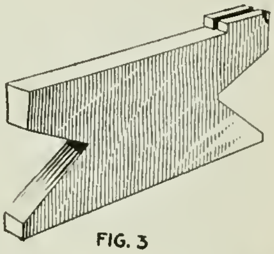

FIG. 3

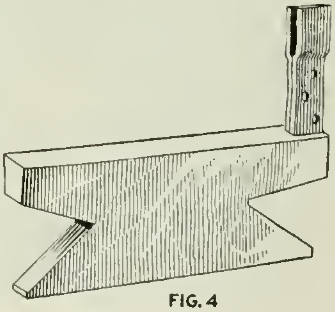

FIG. 4

FIGS. 3 AND 4. TYPES OF COMMUTATOR BARS

The commutator is made up of a number of copper segments similar to the one in Fig. 3, each segment being insulated from the other. These segments are slotted in one end, as shown, so that the armature-coil leads may be easily connected. Many of the large-sized commutators have an extension soldered to each segment or bar, as in Fig. 4, so that, instead of the coil leads being bent down to the commutator, they are brought out almost on a level with the periphery of the armature.

Fig. 5 shows a section through a common type of commutator. The black lines *A* across the surface are insulation, usually mica, between the segments. The heavy black lines *B* are also insulation, therefore it is evident that each segment is insulated from the iron or steel form. Each division on the commutator is called a bar or segment. The bars and insulation are assembled on the vee and sleeve *C*. Then the front vee, *D*, and its insulation are put in place and the nut *E*, which is threaded on the sleeve *C*, is screwed up as tight as it can be drawn. On account of the expansion and contraction of the commutator, caused by wide variations of temperature and strains due to centrifugal force, it is necessary that the clamping rings hold the bars and insulation very tight, or there will be a movement of the bars that will cause serious trouble.

The insulation used between the bars is usually mica or micanite, about $\frac{1}{32}$ in. in thickness, and in fact this is the only material that has been found that will stand up under all conditions. Micanite consists of thin flakes of mica built up into sheets and held together by a suitable binder. In some of the small-sized commutators, during the last two or three years, the bars are molded into the metal sleeve with an insulating compound. This construction for small-sized machines seems to give satisfactory results. In the early development of the art various material were tried for insulating commutators, such as red fiber, fish paper, asbestos, etc., and various combinations of these materials and also mica and other insulations built up in alternate layers, but all have been discarded.

One of the troubles with most of the substitutes for mica insulation in commutators is, they are easily eaten away in case of sparking at the brushes. Furthermore, all fibers or papers are subjected to more or less contraction and expansion due to moisture conditions. This eventually led to slight looseness between the bars and insulation, so that oil or copper and carbon dust could penetrate and cause pitting of the commutators. One of the chief requisites of a commutator insulation is that it shall not be affected by moisture and changes of temperature; also, it must possess a certain elasticity so that it will fill the space between the bars irrespective of the expansion and contraction of the commutator. So far, mica seems to possess these requirements to a greater extent than anything else. The story of commutator insulation is one of the most interesting chapters in the history of electrical development.

Many other kinds of commutator construction are used, especially in the older types of machines, besides that shown in Fig. 5, some of which are indicated in Figs. 6 and 7, from which it is seen that the general principle is the same. In the larger-sized machines the commutators are built upon a cast-iron spider, the same as the armature core. Fig. 8 shows a cross-section of a large commutator that is representative of large-sized construction.

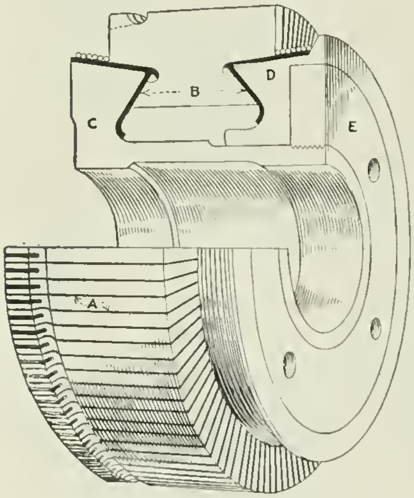

FIG. 5

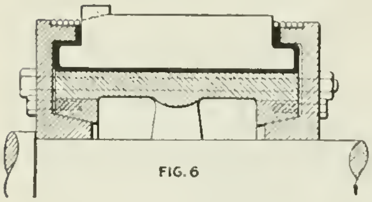

FIG. 6

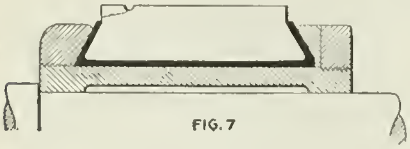

FIG. 7

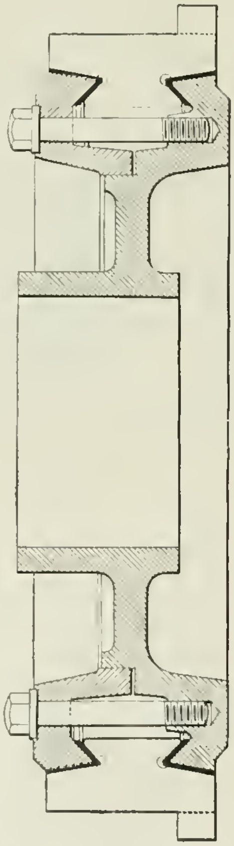

FIG. 8

FIGS. 5 TO 8. TYPES OF COMMUTATORS

In problem 1 given in the last lesson, the cross-section of the conductor was 18,750 cir.mils. The resistance per foot of copper is $R = \frac{10.7}{\text{cir.mils}} = \frac{10.7}{18{,}750} = 0.00057$ ohm. When 35 amperes is flowing through the conductor, the volts drop per foot is $E_d = RI = 0.00057 \times 35 = 0.01995$ volt.

Fig. 9 is a layout of problem 2 given in the last lesson. If the cross-sectional area of the line conductors is 6530 cir.mils, or No. 12 B. & S., then their resistance is that of 150 feet of No. 12 wire, from which $R_1 = 150 \times 0.0016 = 0.24$ ohm. The resistance is also $R_1 = \frac{10.7L}{\text{cir.mils}} = \frac{10.7 \times 150}{6530} = 0.24$ ohm.

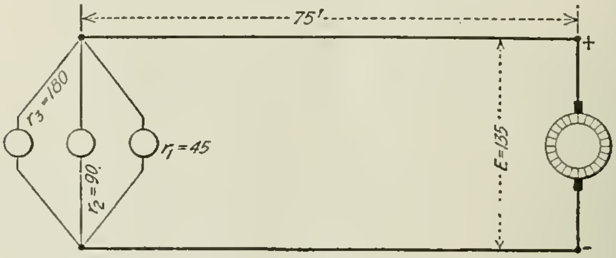

FIG. 9

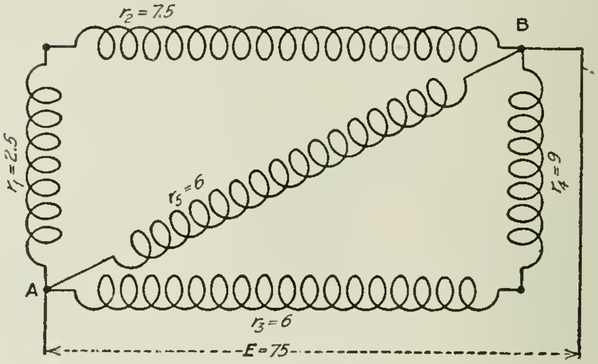

FIG. 10

FIGS. 9 AND 10. COMPLEX CIRCUITS

The joint resistance of the three lamps in parallel is

$$R_2 = \frac{1}{\frac{1}{r_1}+\frac{1}{r_2}+\frac{1}{r_3}} = \frac{1}{\frac{1}{45}+\frac{1}{90}+\frac{1}{180}} = \frac{1}{\frac{7}{180}} = \frac{180}{7} = 25.7\,ohms$$

Then the total resistance of the circuit is $R = R_1 + R_2 = 0.24 + 25.7 = 25.94$ ohms, and $I = \frac{E}{R} = \frac{135}{25.94} = 5.2$ amperes.

The value of the current in the circuits will be inversely proportional to their respective resistances; that is, since r_3 has the highest resistance of the three lamps, the value of the current in this circuit will be the lowest. Since r_2 is one-half the value of r_3, if one part of the current flows through r_3, two parts will flow through r_2, and as r_1 has only one-quarter the resistance of r_3, if one part of the current flows through r_3, four parts will flow through r_1. From this we can say that the current may be divided up into seven parts, one part flowing through r_3, two parts through r_2 and four parts through r_1. If seven parts equal 5.2 amperes, one part equals $\frac{5.2}{7} = 0.743$ ampere, two parts equal $0.743 \times 2 = 1.486$ amperes and four parts $= 0.743 \times 4 = 2.972$ amperes; that is, r_3 takes 0.743 ampere, r_2 1.486 amperes and r_1 2.972 amperes.

Another way of finding the current in the three circuits is to find the value of the volts E_a at the lamp terminals, and then by Ohm's law find the current in each circuit. The volts drop in the line is $E_d = R_1 I = 0.24$

$\times\ 5.2 = 1.248$ volts, and $E_a = E - E_d = 135 - 1.248 = 133.752$ volts. Then the current in r_3 is $i_3 = \frac{E_a}{r_3} = \frac{133.752}{180} = 0.743$ ampere; in r_2 is $i_2 = \frac{E_a}{r_2} = \frac{133.752}{90} = 1.486$ amperes; and in r_1 is $i_1 = \frac{E_a}{r_1} = \frac{133.752}{45} = 2.972$ amperes, which checks up with the values obtained by the foregoing methods.

1. In Fig. 10, find the joint resistance between points *A* and *B*. If points *A* and *B* are connected to a 75-volt circuit as shown, what will be the total current flowing in the circuit and the current in each branch?

2. At 115 volts a given circuit takes 15 hp. Find the current flowing in the circuit and the ohmic resistance.

Garabed: Boon or Buncombe?

Jules Verne in all his vivid imaginings never conjured up a more astounding and unbelievable story than that which is being told by Garabed T. K. Giragossian, a naturalized Armenian, who claims to have discovered a supply of free energy and to have invented and perfected a means whereby that energy can be converted into usable forms. He denies emphatically that it is perpetual motion or that it in any way controverts the law of conservation of energy, over which so many would-be inventors have tripped. He simply makes use of an inexhaustible quantity of energy that exists everywhere and that cannot be monopolized.

No one except the inventor has any information as to the exact nature of the free energy or the method by which it is used. He has firmly and consistently declined to divulge the secret until both the idea and the machinery for its development have been fully protected. This has been accomplished by the passage, on Jan. 16, of a joint resolution by Congress, authorizing the acceptance of the invention for the free use of the United States Government, protecting the inventor for a period of seventeen years, and providing for the appointment of five eminent scientists (to be approved by the Secretary of the Interior) to determine whether the discovery is a splendid benefaction or a stupendous bluff.

Mr. Giragossian, who is a citizen of Boston, has named his discovery the Garabed. With it he proposes to displace the steam engine as a prime mover. The steam boiler will be relegated to the scrap heap or the museum of antiquities. Smoke troubles will be at an end, for coal will be no longer needed for fuel. Petroleum will be used largely for making soap. The industries of the earth, the needs of the home, the illumination of cities, all the innumerable activities of humankind will eventually depend on the Garabed.

So far as it is possible to conjecture, the atmosphere is the inexhaustible reservoir of energy to which Mr. Giragossian refers, for, at a hearing before the House Committee on Patents, he was asked whether his process or contrivance is applicable to the submarine, and he declined to give an unequivocal answer. He does claim, however, that the motor by which he utilizes the free energy can be used for ship propulsion, haulage of railway trains, driving airplanes, production of electricity, pumping water, and doing the thousand-and-one things that have hitherto been done by steam engines and other types of motors; and he claims further that his motor will operate with the same certainty and regularity in all climates and at all altitudes, without human assistance.

The advantages of such a device—if it actually exists outside the imagination of Mr. Giragossian—are obvious. It is absolutely independent of auxiliary apparatus, for it is complete in itself, whereas the steam engine must have a boiler with its furnace, pump and other accessories. The Garabed is much smaller and lighter than the steam engine of equal output, is easily portable and will produce power anywhere at no cost other than the wear and tear on the machinery. With practically unlimited power at little or no expense, human labor will be vastly lightened and labor troubles will disappear. At the same time the productive capacity of industry will be enormously increased, and the present era of prosperity will be insignificant in comparison with that which will come when the Garabed is used universally.

© Harris & Ewing

GARABED T. K. GIRAGOSSIAN

The effect on social and economic conditions will be equally startling and revolutionary. Free energy in unlimited amounts will result in the production of an abundance of all those things necessary to the existence and comfort of the race. Thus, poverty will be wiped out and luxuries made the heritage of all.

Such prophecies as these have been made before and have been met by the sneers and laughter of all classes of people. Mr. Giragossian has not been exempt from ridicule; but his unwavering faith in himself and in the incalculable value of his discovery has made him indifferent to the derision of his fellowmen. For twenty years he has patiently pursued the task of developing his idea and rendering it available for general use. Three years ago he perfected the device, and since that time he has been trying to have it protected so that he shall not be robbed of the credit and the benefits of the invention.

The adoption of the joint resolution does not obligate the United States to buy the invention. If the committee of five eminent scientists decide that the Garabed is practicable, then the United States may, at its option, purchase from the inventor the exclusive right to utilize the discovery. The sum to be paid, in case the option to purchase is exercised, will be settled upon by a committee of even number, half of whom are to be selected by the Secretary of the Interior and the other half by Mr. Giragossian, and the verdict of this committee is to be subject to the approval of the Secretary of the Interior and the inventor. If the United States decides not to buy the invention, the rights of Mr. Giragossian remain, as guaranteed by the resolution.

It is significant that this man's enthusiasm, sincerity and intelligence so impressed the Committee on Patents and other members of the House that the resolution was adopted by a vote of 234 to 14. In the Senate it was approved without much debate, on the recommendation of the Patents committee. By this means the upper body relieved itself of being held up to ridicule in case the Garabed fails to demonstrate its inventor's claims.

TRUTH OF CLAIMS REMAINS TO BE PROVED

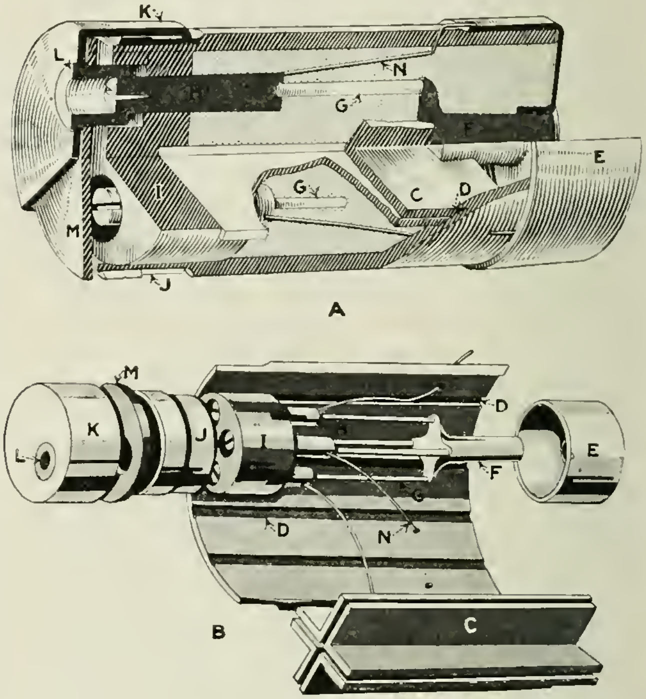
The ability of Mr. Giragossian to substantiate his assertions, by the exhibition of a motor that will run without the application of any of the commonly known forms of energy, remains to be proved. The inventor himself is confident and unperturbed, reiterating that he can and will do all that he has promised, and more. If he succeeds, as everyone would be glad to see him, the United States will have in its possession an agency by which the war can be brought to an end with stunning suddenness and certain victory; and in the peaceful years that will follow, the same agency will give to the nation an increase in material prosperity and happiness such as the world has never seen.

It is foolish to regard Mr. Giragossian as a harmless lunatic. That which he proposes is fantastic in the extreme and subversive of fixed ideas. But it must be remembered that people ridiculed the possibility of the airplane, the wireless telegraph and scores of other scientific discoveries that have now become familiar factors in everyday life. We are in an age of searching investigation and rapid development. The impossibilities of yesterday are the achievements of today; dreams of yesternight are realities tomorrow. It is unwise and unsafe to pass judgment on the discoverer of the Garabed. If he proves his assertions, the world will acclaim his genius and laud his perseverance. If he fails, his extravagant promises will be a boomerang that will knock him into the darkest corner of that limbo reserved for perpetual-motion cranks and other power-generating fakers.

Four-in-One Cartridge Fuse

No doubt many readers will recall the description of the Six-in-One plug fuse appearing in the July 11, 1917, issue of *Power*. Recently a four-in-one cartridge fuse, known as the Atlas fuse, has been placed on the market by the Atlas Selling Agency, New York City. A sectional view *A* and a view *B* of the fuse exploded are given in the figure.

From the outside this new type of fuse looks the same as the standard type of cartridge fuse and can be used anywhere that standard fuses are used. However, instead of a single chamber, as in the ordinary type of cartridge fuse, the inside of the shell is divided into four compartments by four pieces of fiber, bent and assembled as shown at *C* in both views. The fiber compartments fit into grooves *D* in the fiber-containing shell, making a very strong construction.



SECTIONAL VIEW AND PARTS OF FOUR-IN-ONE CARTRIDGE FUSE

One end of the fuse shell is equipped with a stationary brass cap *E*. From the center of this stationary cap is a copper extension *F* from which four fuse wires *G* run through the four separate compartments to four copper terminals *H* held in a short solid-fiber cylinder *I* at the opposite end of the fuse. On the end of the fuse shell containing the four copper terminals *H* and fiber cylinder *I* is placed a stationary brass ferrule *J*. Fitted over the stationary ferrule is a movable brass cap *K*, containing a copper receptacle *L* that fits over one of the copper fuse terminals *H*, as shown in the sectional view. This completes the circuit through the fuse from the movable cap *K* to the stationary cap *E*. The copper terminals *H* are slotted in the end that the receptacle fits over, to give them a spring and make a good contact in the receptacle.

If a fuse blows, all that is necessary is to remove the cartridge from the clips, pull cap *K* out about ¼ in. and give it a quarter turn, push back the cap and another fuse element is in circuit. Replace the cartridge in the clips and the circuit is again ready for service. To prevent making contact with any fuse element other than the one that is intended to be in circuit, a fiber washer M is placed in the top of the movable cap K. The blowing of a fuse element is indicated as in a standard fuse, by a fine steel wire N, that extends from the copper terminal H to the stationary cap E. Each fuse element is solidly packed in its chamber with an insulating powder. This new type of fuse is approved by the Underwriters' Laboratory and is made with ferrule contacts in all amperages up to and including 60. All measurements and dimensions are N. E. C. standards, thus assuring a perfect fit in every type of N. E. C. standard panels, switchboard and inclosed-fuse cutouts.

Velocity of Air in Ducts

After the velocity head of air in a chimney or duct is found by means of a manometer or U-tube, its velocity is calculated by the formula,

$$v = \sqrt{2gh}$$

where v = velocity in feet per second, h = velocity head in feet, and g = acceleration due to gravity in feet per second = 32.16 feet.

When the manometer contains water and the velocity of air is being determined, the head must be changed from inches of water to feet of air by multiplying by the ratio of the density of water to that of air. To do this the temperature of each must be known, as the weight of a cubic foot of air or water changes with variation in temperature. To illustrate, assume that the manometer reading h (the difference in level) is one inch of water and that the temperature of the water and of the air is 60 deg. F. From standard tables, the weight of one cubic foot of water at 60 deg. is found to be 62.37 lb. and of a cubic foot of air at the same temperature is 0.0764 lb., or the height of the column of air in feet to represent the same pressure as one inch of water would be $\frac{62.37}{0.0764} \times \frac{1}{12} = \frac{816.4}{12} = 68.03$ ft. In other words, water is 816.4 times as dense or heavy as air at the temperature taken, so that a column of air 816.4 in., or 68.03+ ft., would equal or balance a column of water one inch high or that difference in level in the U-tube manometer. Then applying the equation, the velocity of the air is found to be

$$v = \sqrt{2gh} = \sqrt{2 \times 32.16 \times 68.03} = 66.2\ \textit{ft. per sec.}$$

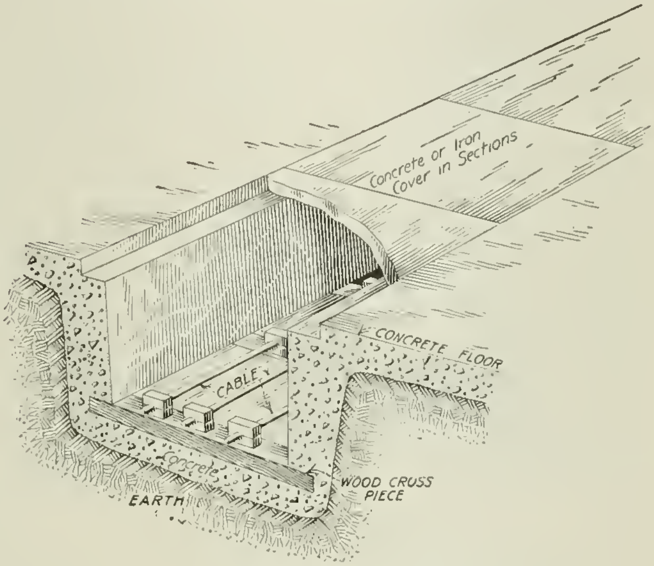
For any other temperatures, or if mercury is used in the manometer in the place of water, the proper weights per cubic foot will have to be used.

Installing Electric Cables Under Concrete Floor

By D. R. Shearer

Sometimes it becomes necessary to run heavy light and power cables under concrete for some distance, as for instance, from the generator to the switchboard in a power plant or from the transformers to the switchboard in a substation. Of course conduit is an excellent runway for such cables, but at times this is difficult to secure and some substitute becomes necessary.

An excellent method is to place a trough form in the earth floor before the concrete floor is laid. On the bottom of this form are placed cross-pieces of creosoted wood about three feet apart and slightly longer than the trough is wide. After the concrete sets the form is taken out, leaving the cross-pieces embedded in the bottom of the cement trough.



SECTIONAL VIEW OF CABLE DUCT

The cables are then cleated to the cross-pieces with porcelain cleats and heavy screws. Either iron or reinforced concrete may be used as a cover for the duct. This can be removed at any time for cleaning the cables or attaching other leads. The figure gives a sectional view of the duct construction.

To Determine Heating Requirements

By M. William Ehrlich

Under the present stress it is more important than ever to provide adequate heat for the comfort of workers, lest quality and output be impaired. Suppose a case of a corner office or workroom that could not be heated satisfactorily although it had been figured by the old rule allowing one square foot of direct steam radiation to take care of 80 cu.ft. of space and accordingly a radiator having 30 sq.ft. of heating surface was installed. Experience has shown this to be wrong. The mistake was made in using a thumb-rule to arrive at the radiator size. This has often proved to be a dangerous procedure unless seasoned with judgment based on ripe experience.

The cubical contents of a room have but little to do with its heating requirements. They enter into the question only as regards air leakage or ventilation, and in direct heating this factor depends mainly on the infiltration of air leaking through the door and window crevices. This has been found to average one air change per hour when doors and windows are closed. When some form of ventilation is desired, more air may be admitted through windows or otherwise, and the radiators must be proportionately larger to take care of this air change in the room. The cubical contents of the room are therefore taken to represent one change of air an hour which is usually but a small portion of the heating requirements, as will be shown. What does count, however, is the weather exposure and the materials used in the wall construction. The "exposure" is that part of the wall of a room or building which is subjected to the direct action of the outside weather, such as the walls, windows and doors facing on a street or other open space and also the roof. The chief heating work to be done depends on the losses through such exposed surfaces and is a component of the aggregate of such surfaces, their material and thickness and the difference in temperature between the indoor and the outside air. Thus, when it is —5 deg. outside and 65 deg. indoors, the difference is 70 deg., or with +10 deg. out of doors and 70 deg. indoors the difference in temperature is 60 deg. A temperature difference of 70 has become a standard for calculating radiator sizes in the eastern section of this country as well as elsewhere if climatic conditions are similar.

The demand on a heating system naturally varies with the fluctuations of the outdoor temperature, but the radiators must be selected to adequately serve the maximum difference in temperature. The total heat loss for any condition is the sum of the transmissions through all the surfaces and for air change, for any difference in temperature between inside and outside air.

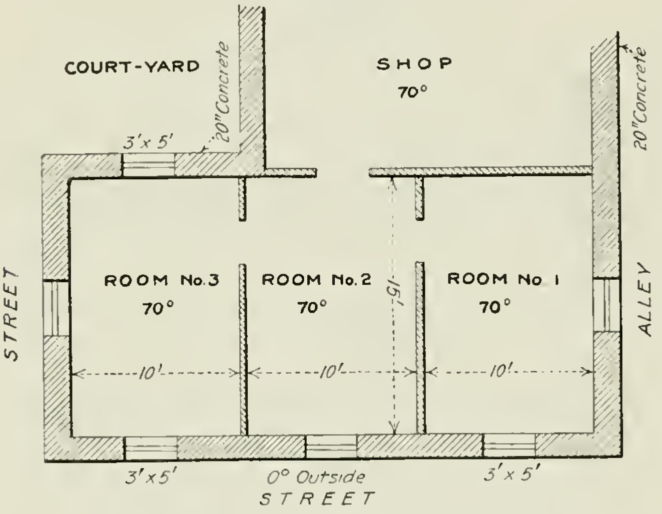


FIG. 1. CONTRAST IN HEATING REQUIREMENTS

As an illustration take a room arrangement as shown in Fig. 1, where each of three offices adjoining has a cubical contents of 1500 cu.ft., or an inside measurement of 10 x 15 ft. with a ceiling height of 10 ft. The windows are 3 x 5 ft. each and the outside temperature is taken at zero while 70 deg. is maintained indoors. Room No. 1 has two outside walls, a gross exposure of (15 and 10 times 10 ft. high) 250 sq.ft. Two windows (30 sq.ft. of glass) deducted from 250 leaves 220 sq.ft. net for exposed wall. No. 2 has one (10 × 10) 100 sq.ft. gross wall exposed to the weather, less 15 sq.ft. for the window, leaving 85 sq.ft. net wall exposure. No. 3 has three sides 10 + 15 + 10 = 35 times 10 ft. high, or 350 sq.ft. gross wall exposed, less three windows, or 45 sq.ft., leaving 305 sq.ft. net wall exposure. With such great differences in the surfaces through which heat is lost, each room will require a different amount of radiation, but on the basis of cubical contents each would get a radiator of the same size or, say, 80 cu.ft. to one square foot heating surface would be 1500 ÷ 80 = 18¾ sq.ft. This, obviously, cannot be right for three such conditions.

To properly determine what the radiation should be involves a series of computations. To eliminate this figuring the chart, Fig. 2 (p. 225), has been prepared for low-pressure steam and hot-water heating by direct radiation and a difference in temperature of 70 deg. The use of the chart for practical purposes is quite simple as it is only necessary to know the material and thickness of the exposed wall as shown on the scale at line *A*, and the square feet of this exposure as shown on scale *B* In case of air leakage or ventilation this same scale is used for reading cubic feet of air per hour. With these factors determined by examination and measurement or from plans, it is only necessary to lay a straight-edge across from point to point and read the answer from scale *C* for either steam or hot-water heating, adding together the amounts so found for the final answer. For example, take a 16-in. brick wall that has an exposure of 190 sq.ft. net. What is the amount of radiation necessary to compensate for the heat loss through this exposure? Laying a rule across from scale *A* at the point marked for a 16-in. brick wall to 190 on scale *B* gives, as shown, an intersection at scale *C* at 13 sq.ft. steam or about 21 sq.ft. hot-water radiation. The wall exposure is, however, only a part of the total heat loss a radiator would be called on to compensate. The total heat requirement is, of course, the sum of the losses through all exposures and air leakage. In the case of the three rooms shown in Fig. 1 and assuming the outside walls are of 20-in. concrete, the radiator sizes for steam would be found, by the use of the chart, as follows:

Room No. 1:	Determined from Plan, Fig. 1	Readings from Chart, Fig. 2, Sq. Ft. Radn.
Net exposed wall	220 sq ft.	23.0
Windows (single glass)	30 sq.ft.	9.7
1 Air change (contents)	1,500 cu.ft.	7.5
Total radiation		40.2
Room No. 2:		
Net wall	85 sq.ft.	9.0
Glass	15 sq.ft.	4.9
Air change	1,500 cu.ft.	7.5
Total radiation		21.4
Room No. 3:		
Net wall	305 sq.ft.	32.0
Glass	45 sq.ft.	14.8
Air change	1,500 cu.ft.	7.5
Total radiation		54.3

These values are all determined by placing a straight-edge from values on scales *A* and *B* and reading the answers directly from scale *C*. However, 1500, the cubical contents, is not on the chart, so 500 was selected of which 1500 is a multiple. For one air change and 500 cu.ft. the result on scale *C* for steam is 2.5 sq.ft. This multiplied by 3 gives 7.5 sq.ft. as the radiation required to compensate for air leakage. This same method may be relied on for any other values not found on scale *B*, which is limited to 1000. The different values found when added together give the size of radiator required for the given condition, then the nearest commercial size radiator or a pipe coil of the required capacity is made up.

By comparing the results found on a heat-loss basis with those of the thumb-rule ratio method, which gave only 18¾ sq.ft., it is seen why there would be difficulty in heating the corner rooms.

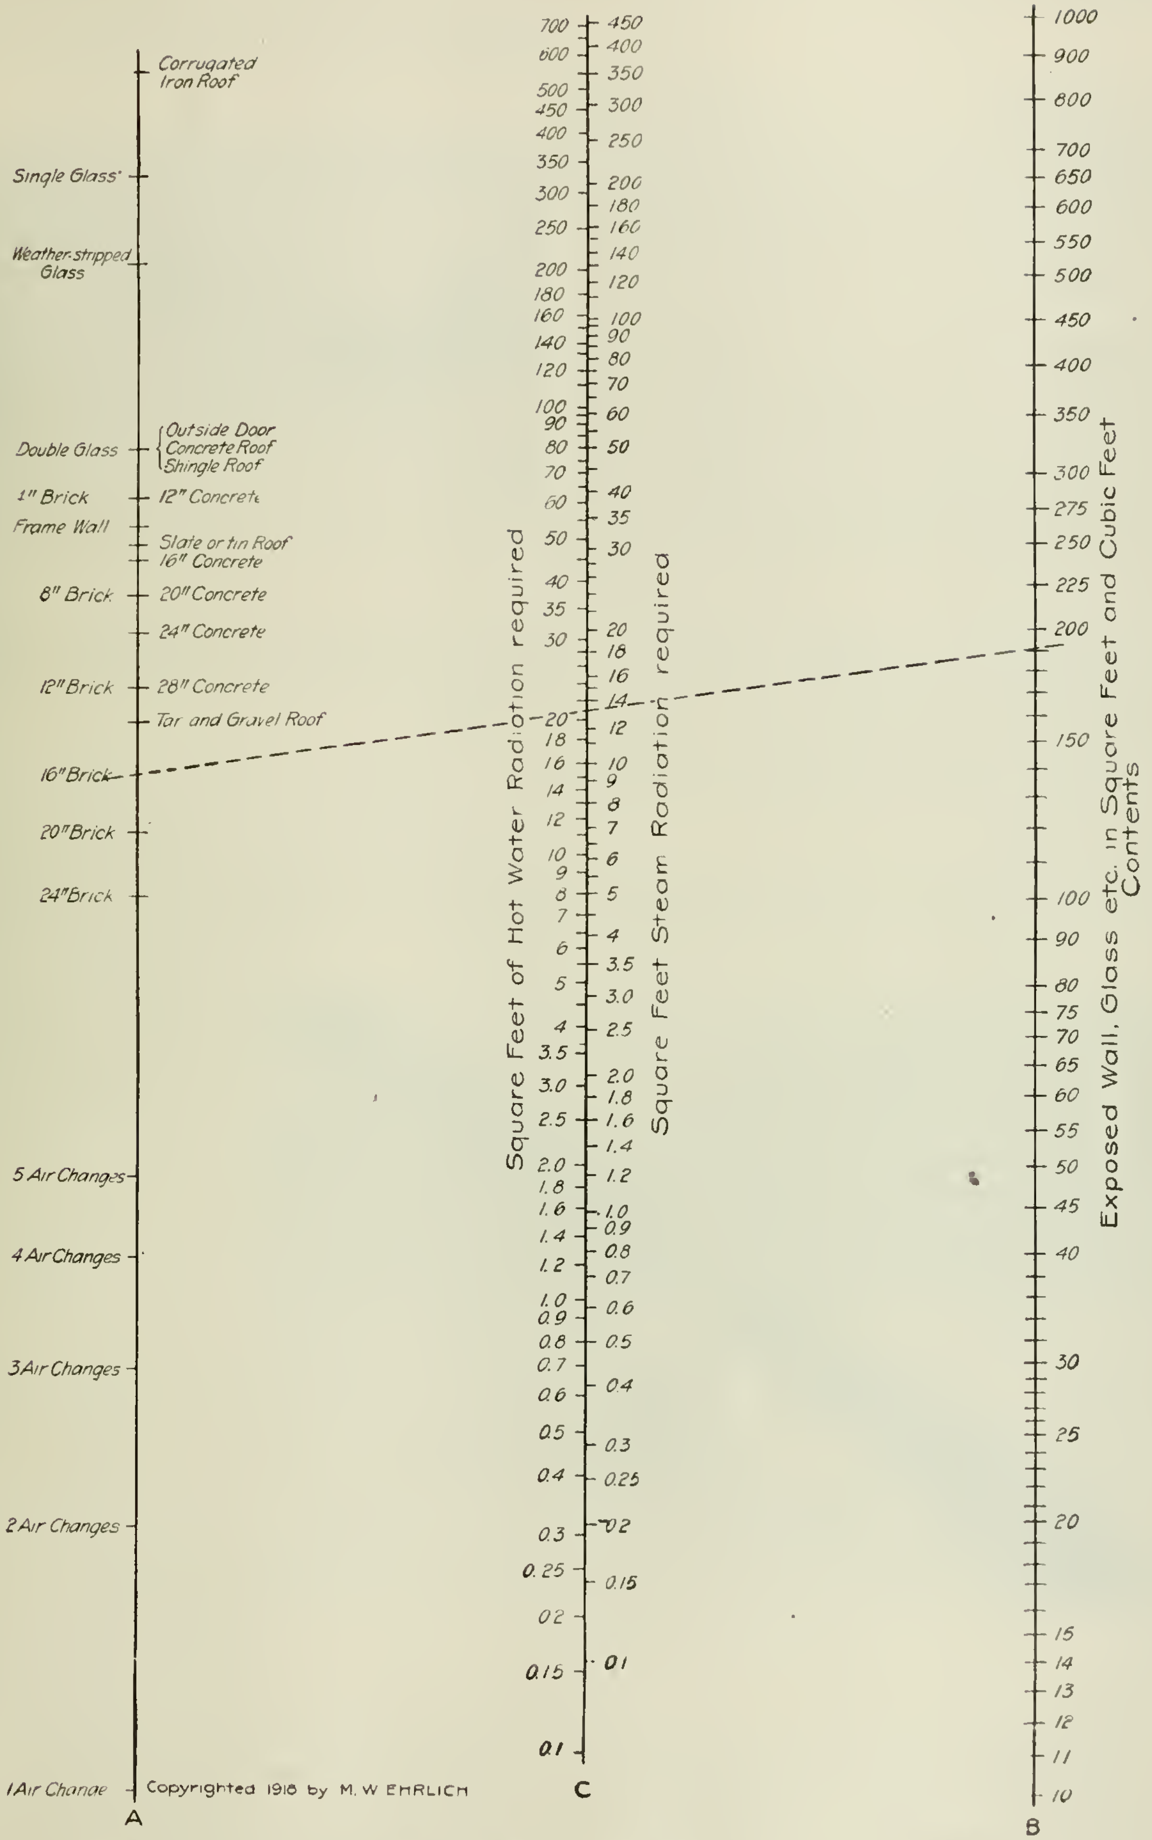

FIG. 2. GRAPHIC METHOD OF DETERMINING THE AMOUNT OF RADIATION REQUIRED

Self-Contained Portable Scoop Conveyors

The handling of coal from railroad cars to the storage pile is often expensive, and the more automatic and simple the apparatus can be designed the less the labor and operating cost involved. There are several types of portable conveyors manufactured, and among them is the portable scoop conveyor made by the Portable Machinery Co., Inc., Passaic, N. J., the design and application of which are shown in the accompanying illustrations.

This machine is of the belt type, and it may be driven either by a self-contained motor or by an internal-combustion engine. It is called a scoop conveyor because the conveying belt receives material through a scoop that can be pushed into the material to be handled. The machine, Fig. 1, is handled by one man in loading or unloading, stacking or reclaiming loose material, such as coal, coke and ashes, at a rate of about one ton per one and one-half minutes.

When used to handle from coal hopper cars, the scoop end of the conveyor is run in on the car and the coal can be elevated from the track level, a distance of from six to nine feet to a storage pile. One advantage of this machine is that by using two or more conveyors, as shown in Fig. 2, the coal can be elevated in successive stages until the storage pile has reached any desired height without the necessity of resorting to shoveling, thus saving in labor.

When used in reclaiming coal from a storage pile, the scoop end of the conveyor is pushed into the pile and the coal is discharged into the car for conveying it to the boiler room. If a storage pile is such a distance from the car track as to be out of the range of the machine, a second unit can be used, the first one discharging into the scoop of the second, which discharges in turn into the car. In this way the coal can be conveyed any distance, the only limit being the number of machines used.

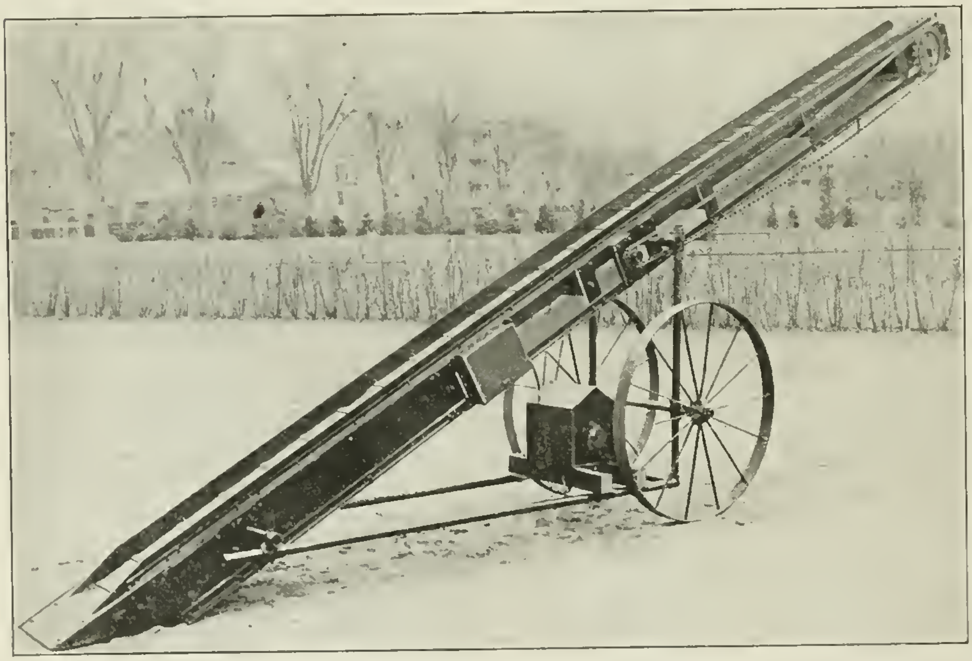

FIG. 1. PORTABLE SCOOP CONVEYOR WITH SELF-CONTAINED MOTOR

The conveyor is built of steel and is mounted on two wheels. The driving motor is mounted on a pipe frame, as shown in Fig. 1, and drives the belt by means of chains and sprockets. When the conveyor is to be moved, two lengths of pipe are inserted into the ends of the horizontal members of the pipe frame, which enables the machine to be easily wheeled from one place to another.

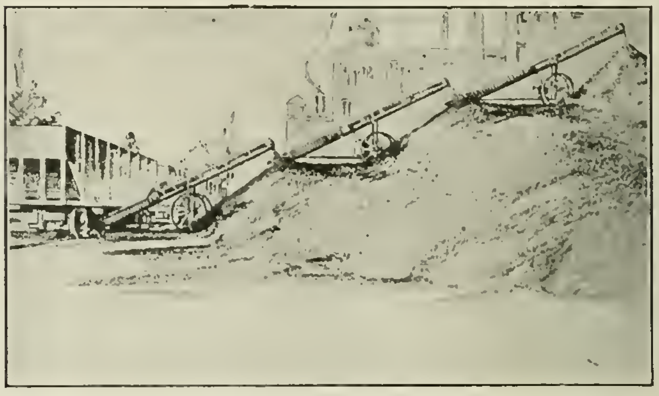

FIG. 2. UNLOADING CAR WITH THREE CONVEYORS

Handling Feed Water at River Station

It will be remembered that in the Feb. 13, 1917, issue of *Power* there was published a description of the River Station of the Buffalo General Electric Co., Buffalo, N. Y. One of the features of this station is the evaporator system for evaporating makeup water. The boilers are run at 300 to 400 per cent. rating, owing to the load demands increasing far more rapidly than plant expansion, the serious situation in load having been brought about by the withdrawal of water power by the Canadian government. The evaporator system has been in service now for nearly a year, and *Power* readers doubtless will be interested to know how the boiler-feed water is taken care of.

The evaporators (Reilly multicoil) are working up to the limit owing to the heavy overloads on the boilers, so that they are not able to supply all the makeup water; but they do supply on the average 98 per cent. of distilled water for makeup purposes. Once every month the water in each boiler is blown down so that the water level is lowered about three inches in the gage-glass. The boilers are opened once every six months, and so far the conditions observed have been excellent. There is no scale, and nothing but a slight amount of mud is found on the lower tubes. There is no pitting.

Editorials

The Solution of Greater New York's Coal Problem

"COAL-DOCK facilities are the key to the whole situation!" exclaimed Harry Peters, chairman of the Conservation Committee of the New York Fuel Administration, when interviewed on January thirtieth. And Mr. Peters is right. We concluded so ourselves, as pointed out in the article, "While the Idle Millions Shiver," in last week's issue. The thousands of tons of coal piling up on the rails at the coal docks or piers where great numbers of barges wait and wait, and the acute shortage in the greater city show instantly that here lie the causes of congestion and shortage.

There is another factor. According to New England Fuel Administrator Storrow the New England States consume forty-two million tons per year, two-thirds to three-fourths of which is ordinarily shipped by water, and most of it is delivered to New England during the six warm months of the year. The reserve supply in storage in these states is gone. Everybody's bin is empty. The industries and business houses in and about Boston must close, says Mr. Storrow, for a period two hundred per cent. longer during the crisis than the National Fuel Administration demands of the rest of the country. New England must make use of rail transportation to the limit of physical possibilities. This means throwing a severe overload on the coal piers located on the New Jersey shore and which also supply New York City, equally straining rail transportation from the mines to these piers and taxing barge transportation from the piers to southern New England.

New York City cannot escape being badly hit by the New England crisis and the great increase in ocean shipping from this port. New York City puts in only one-quarter to one-third of its coal during summer. The city has facilities for only four and one-half days' storage, chiefly because of real-estate values. Along in October the whole city suddenly demands coal, and in April the demand ceases just as abruptly. The unloading piers have been built and equipped to care chiefly for the usual demands of the Greater City. If the city is to be properly supplied, if New England is to be relieved and bunker coal furnished to the ships leaving New York harbor, the present piers are likely to be found to be wholly inadequate even if the whole eleven were worked day and night.

The report of the Conservation Committee upon its investigation of conditions at the eleven coal piers supplying New York City, published in our last week's issue, page 193, clearly reveals that the piers are not working at capacity, that they are inadequately equipped, undermanned and working but part time, considering twenty-four hour day operation imperative in this crisis. What is the good of rejoicing at the news in the papers each day that so and so many thousand tons of coal arrived at tidewater? It means nothing if the coal merely dribbles beyond that point.

But the conditions are more severe than is revealed by the report. The Conservation Committee says that for twenty-nine days last month the eleven piers together averaged 1335 cars unloaded per day, as against 1800 per day last year. So far as we can learn the railroads operating the piers say they can unload but 1300 per day. Their best performance was on January twenty-ninth, when they unloaded 1719. The Conservation Committee, the fuel administrators and the coal dealers know that unless the docks can average about 2000 cars per day, all hope of relieving the present situation is vain.

It is up to the coal-pier management to do this. If the local fuel administrators and the railroad representatives cannot get together and make these provisions at once, it certainly becomes the duty of Mayor Hylan and Governor Whitman to demand that Dr. Garfield and Director General McAdoo authorize someone to use a big stick here at tidewater.

The chief reason why the movement of anthracite is so slow at the piers seems to be lack of coal-pooling arrangements rather than physical impediments. According to the Conservation Committee it handed its report to A. H. Wiggin, Fuel Administrator for New York State, and to Dr. Garfield over a month ago, or on or about the date of its issue, which was December thirty-first. This report stated "that this committee recommends the pooling of *all coal* so that no additional time may be lost in switching." The italics are ours. Despite the urgent need of putting that recommendation into immediate effect over a month ago, only today (February fourth) have arrangements been put in force whereby barges may load with any coal available at the piers. And as this goes to press we are advised by the State Fuel Administration that this applies to three piers only; namely, those on the Delaware, Lackawanna & Western, Lehigh Valley and Erie railroads. It is hoped that they will go into effect for the other piers at an early date. The reader should understand that there is no pooling of anthracite as related to sizes.

There has been a considerable increase in demand for coal going over these piers, says the Conservation Committee. Twenty-five per cent. of the coal handled by them now goes to New England. Ships coaled in New York for transatlantic service must be provided with sufficient fuel to carry them across the ocean and back again, instead of one way only, as formerly done. It is likely, then, that at the capacity at which the piers are now worked the coal will continue to pile up in the yards, tying up more and more cars until a shortage of empty cars demoralizes mining. This is the very thing above all that should not happen through causes originating at this port. New York affords one of the best hauls in coal transportation. It is only a little over two hundred miles from the anthracite mines and about three hundred from the bituminous mines to tidewater, and a short tow, about twenty miles, from tidewater to the city. It is New York City's vital concern how the coal piers supplying the city are equipped and managed.

While the Mayor logically looks to Mr. Wiggin, State Fuel Administrator, and to Reeve Schley, Administrator for Manhattan, also to the other administrators for the city, to keep him informed, he must appreciate that these gentlemen interest themselves chiefly in individual consumers' complaints and adjustments. It is a veritable riot of activity in the offices of fuel administrators the country over, so voluminous and varied are these pleas and "howls." The Mayor has wired and phoned to Washington for priority in shipment. New York does not need priority. If he will, through a representative who has investigated, concentrate his demands on improving the loading piers, he will get greater results.

The question of labor is by no means a negligible one at these piers. First, the function performed by labor there during this crisis is indeed a vital one. The work is not attractive. The piers are wind-swept and much of the coal is badly frozen. The men are paid, so far as we can learn, but thirty-five cents an hour. The pier management should not lose sight of the fact that the new shipyards and many other plants near all these piers employ tens of thousands of men and will soon demand more. The laborer in the section in which these piers are situated, particularly the laborer in Government work, is getting considerably more than thirty-five cents an hour.

Clear the coal docks in New Jersey, add to their discharging capacity. Relief cannot come until this is done and the railroads are unhampered by red-tape rules.

The Ammonia Situation

NOW it is an ice famine that confronts Greater New York. Senator Wagner and Former Governor Odell estimate that the Greater City faces a shortage of 2,500-000 tons. The State Legislature at this writing contemplates harvesting ice now while it is at its best, piling it on the banks of the Ashokan Reservoir, the Croton Lakes and other places, until storage houses can be built to hold it.

The reason is that New York City relies upon artificial ice for the greatest part of its supply. Ammonia is, of course, required for ice making. But the report is current that little of this refrigerant is or will be available because those products from which it is made are sorely needed for munition purposes and for Southern cities which cannot get natural ice.

All this sounds reasonable, particularly as related to New York City. Most of the ice harvested may be transported to the city by barge, which does not require freight cars nor add to the congestion on the railroads.

One thing is sure: It is difficult to overestimate the importance of an adequate supply of ammonia for refrigerating and ice-making purposes. Refrigeration plays a most essential rôle in our national life, a rôle that has not only enlarged tremendously in recent years, but has so changed our whole system of transporting, storing and consumption of foodstuffs that to try to abruptly effect a marked change in any of these would be followed by a calamity as great as, if not greater than the fuel crisis.

Now above all times there should be a full supply of ammonia on hand. In five or six weeks the winter will break and the load on refrigerated warehouses and cooling systems will rise like a kite string. The refrigerating plants should start each with a full charge of ammonia. One cannot hoard ammonia by overcharging the system, because compressor operation will not permit of it without prohibitive mechanical trouble. Because excess ammonia must be stored in drums in the average plant and because it is easily possible to keep a record of sales, hoarding should be easily prevented.

It will not do for the Federal authorities to be too hasty in withholding ammonia, particularly from warehouse companies storing food. Considerable discretion is not only desirable but imperative. Food is now under Governmental control. On the whole owners and operators of these warehouses do not own the food. They must not be driven or goaded to an attitude of irresponsibility—to a state of mind that would bring about a condition whereby the food stored might spoil due to a shutdown for lack of ammonia or other causes. With the Federal authorities in control of food and the essentials necessary to its preservation, and when someone else owns the food, it is not a far cry to unloading on the Government, to "passing the buck next door." These warehouses may properly be regarded as public utilities. But the Federal authorities cannot be unmindful of the fact that they present a totally different problem, as related to service interruptions, from that presented by railroads or the electric-power utilities, for example. These can pick up the load where they dropped it. A refrigerating plant rapidly reaches a critical stage once the refrigerant ceases to circulate through the system. While the rolling stock of the railroad and all freight except perishable, and the transmission lines and lamps of the electric utilities suffer no deterioration while the "power is off," the foods in cold storage immediately start on a road whose end is ruin as soon as the compressors are stopped.

Not until every source of the raw materials from which ammonia is made is worked to its limit, not until everything has been done to develop new sources, should ammonia be withheld. Happily, the Government, is preparing to manufacture ammonia on a great scale.

The Great News

THE article by Dr. C. R. Mann, on page 217, has a significance beyond that suggested by its title. Although irrelevant to the field of *Power*, it is good reading for anyone who is observing the direction in which things are drifting in these times, when so much that was regarded as immutable has broken loose from its moorings and so much that was apparently crystallized is in a state of flux.

If we are now to "envisage an entire community as a single working plant for the purpose of organizing it for the production of human wealth"; if industry and commerce are to be "organized to make goods cheap and men dear"; if "public service rather than excess profit is to become the inspiration for enterprise"—then indeed will "the engineer and not the banker become the power behind the throne" and the word efficiency take on a new and broader significance.

Correspondence

Peening Pipe in Its Flanges

A steam line that once came under my observation gave trouble by leaking at the threads in the flanges. To my knowledge it was taken down three times and the ends of the pipes calked against the flanges. If, instead, with a ball-peen hammer, the pipe had been peened into the flange and back for a distance equal to the thickness of the flange, the job would have been more successful.

Many engineers make a practice of heating the flanges before screwing them on a pipe, believing that when they cool the joint will be tight. So far I have failed to get good results that way, but have always made it a practice to see that the pipe is well peened into the flange. The pipe should be screwed in to come flush with the face of the flange. If one has a lathe, the flange can be turned off a small amount at the inside edge. The pipe can then be screwed in so it projects through, and after it is peened into the flange and the recess, it can be faced off with a file, making a job that will stay tight. N. C. GLEASON.

Hoisting Boilers to Second Floor

The boilers in the new plant of the Studebaker Corporation at South Bend, Ind., weigh 30 tons each and had to be placed on the second floor twenty feet above street level. I secured a double-drum hoisting engine and rigged up two sets of blocks with a ⅝-in. steel cable, fastened one end to an overhead beam in the building and the other to the boiler with cables and clamps. The leads ran from the upper blocks to snatch-blocks on the building column, thence down the column to the ground and through other snatch-blocks to the drums of the hoisting engine, all snatch-blocks being fastened to the building column with cable and clamps.

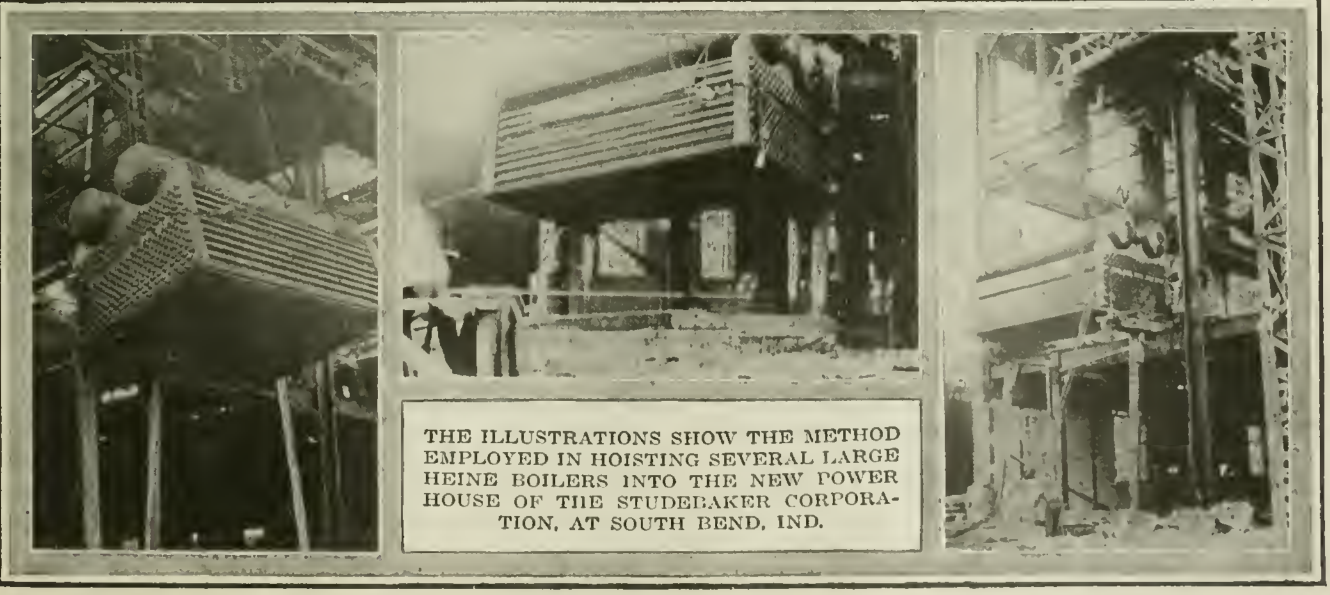
We hitched 1½-in. rope blocks to each end of the boiler to hold it away from the building and to let it come in gradually after hoisting it above the second floor. We also had a pair of skids from the ground to the second floor and two planks lashed to the tubes for the boiler to slide on, as it went up, to protect the tubes.

In hoisting, we raised each end six feet at a time until we had the boiler four feet above the second floor. We then slacked off on the rope blocks and placed two 14-in. x 14-in. x 20-ft. timbers under each water-leg, letting them extend five feet out from building. On these we put three rollers with a 3 x 12-in. plank on top of rollers and lowered the boiler to rest on these planks slightly and, with two rope blocks within the building, moved the boiler over into place. The time required after the rigging was set was just one hour to hoist and land each boiler, and there was no damage done to man or material on the entire job.

St. Louis, Mo. C. C. MULDNER.

Regulating Fuel-Oil Burners

I wish to add to the letter by Edward M. Walker, on page 807 in the issue of Dec. 11, regarding the proper method of regulating fuel-oil burners, that economical combustion is not assured unless strict attention is given to damper or air regulation, and in boilers of the B. & W. type using back-shot burners the proper place to observe the flame is through the small holes in the settings for soot cleaning, in the first pass opposite the second or third row of tubes where the end of the flame may be seen; then with the atomizer set so as to produce a clear flame, the breeching damper should be gradually closed until the end of the flame appears red



THE ILLUSTRATIONS SHOW THE METHOD EMPLOYED IN HOISTING SEVERAL LARGE HEINE BOILERS INTO THE NEW POWER HOUSE OF THE STUDEBAKER CORPORATION, AT SOUTH BEND, IND.

or slightly smoky. In this type of setting the flame is directed toward the front, and with a heavy fire curls back over the top of the main flame body, ending in the lower part of the tube bank; therefore no idea of the actual condition of the fire can be had by observations taken at the front—that is, through the fire-door—because the fire may be quite smoky either from insufficient atomization or a deficiency in the air supply, while the color of the main body of the flame is not noticeably changed, but a glance at the tip of the flame will plainly reveal the condition.

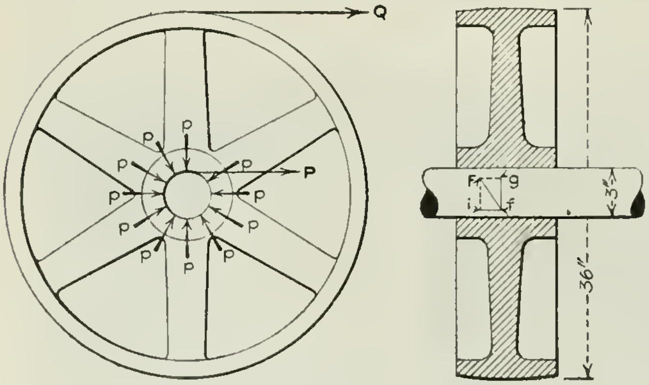
In some oil-burning plants the firemen are given instructions to so regulate the dampers that a faint haze will appear at the stack. The careless ones soon learn that by setting one fire so as to produce the haze the remaining boilers may be operated with the dampers wide open, thus saving them the trouble of regulating the dampers, and the chief or superintendent, seeing the haze coming from the stack, is satisfied. This little trick is often played on the CO_2 recorder when but one boiler is connected to it; that boiler is operated so as to give a good CO_2 reading, while the others are neglected. A. C. McHugh.

Del Monte, Calif.

Why Twist the Pulley?

On page 808 in the issue of June 12, 1917, Sidney A. Reeve asks, "Why is it that in forcing a pulley on a shaft, you can gain by twisting the pulley?"

I think that this may be explained in the following way: Imagine you have a pulley 3 ft. in diameter on a 3-in. shaft, as shown in the illustration, and the pulley is pinched on the shaft by forces p. When a force F is applied to the pulley in order to force it along the shaft, the pulley will move as soon as F is greater than Σpu, in which Σp = sum of pressures p and u = coefficient of friction. When $\Sigma p = P$, then F must be greater than Pu. Let Pu be $fi = 300$ lb., then it will not be easy to succeed without twisting the pulley. It is much easier to turn the pulley round the shaft. You need but apply to the circumference of the pulley a force $Q = 300 \times \frac{36}{3} = 25$ lb., as this force corresponds with a force $fg = 300$ on the circumference of the shaft.



PULLEY TO BE FORCED ON SHAFT

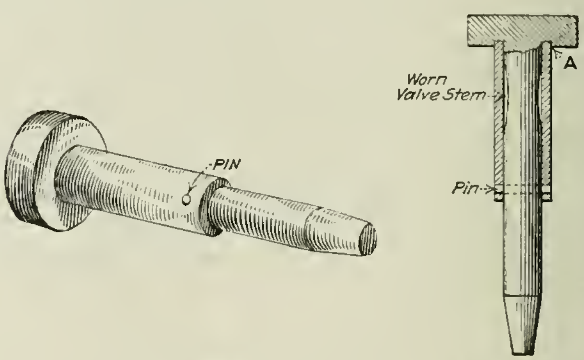
Suppose $Q = 24.9$ lb. or $fg = 24.9 \times \frac{36}{3} = 298.8$ lb. Then the pulley will not turn. At the same time we apply a force $fi = 32$ lb. in the axial direction. The resultant force will then be $fF = \sqrt{298.8^2 + 32^2}$, which is greater than 300 lb. In consequence the pulley will move in the direction of the resultant force fF; that is, it will turn round the shaft and move in an axial direction. If we apply a force $Q = 25$ lb., the force F, be it ever so small, will cause a movement in the axial direction.

This property might be taken advantage of with regard to measuring apparatus, where one wants to eliminate the influence of friction. If only we have at our disposal a turning force of sufficient strength, we can eliminate the friction in the axial direction.

Wageningen, Holland. Y. Brouwers.

Repairing Worn Valve Stems

When the valve stems of a Corliss engine become cut or worn from the friction of the packing, it is expensive, especially in large engines, to replace them with new ones. If the stem is not worn to a dangerously small diameter, the following methods of repairing will be found inexpensive and efficient. The job might be repeated whenever necessary, thus retaining the same stems indefinitely.



VALVE STEM FITTED WITH SLEEVE

The stem shown in the illustration is $2\frac{1}{4}$ in. diameter, with a tee-head $2\frac{1}{4}$ in. square. A piece of drawn steel tubing $2\frac{1}{2}$ in. outside diameter and a scant $2\frac{1}{4}$ in. inside diameter, making a snug driving fit on the stem, was forced on over the valve stem to the position shown at A. The hole in the bracket was bored out $\frac{1}{4}$ in. larger, as was also the gland. The stem was then put in place and packed with packing $\frac{1}{8}$ in. smaller than the old.

The job proved satisfactory and made the stem apparently as good as new.

If I were building an engine, I would have the stems provided with sleeves so that when worn they could be removed and replaced by new ones.

Passaic, N. J. Charles W. Oakley.

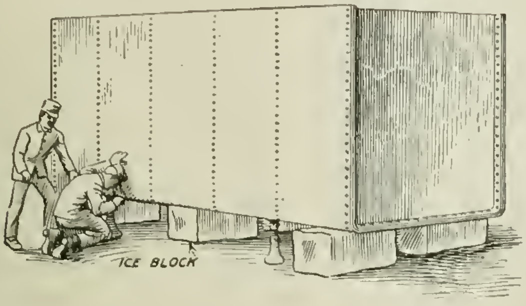
Removing a Key—Not

Of all the "fool stunts" I ever heard of, the following seems to be the limit. A self-styled expert machinery rigger, after sledging at a $\frac{7}{8}$-in. key that had been exposed to the weather for years and failing to move it, looped a few turns of No. 10 galvanized wire around it and hitched a "flivver" automobile to it expecting to draw it out by a steady pull. Did he succeed? He did not. B. C. White.

Spartanburg, S. C.

Lowering a Heavy Tank

At a certain plant a large tank was to be lowered from an elevated position to the floor. The job proceeded smoothly by successively blocking and lowering with jacks, until at last the tank was resting on the jacks with their bases on the floor. The problem then was to get it the rest of the way down. This was accomplished as follows: The tank was lifted slightly and blocks of ice placed under it. The jacks were then removed and warm water flushed around the ice and the tank gradually settled into place. J. M. **Purcell.**



LOWERING THE TANK TO REST ON BLOCKS OF ICE

Richmond, Va.

A Groaning Steam Pump

Following is my experience with a groaning pump. It was a Worthington duplex 16 by 12 by 12 plunger pattern, and furnished water at 90 lb. pressure to operate three hydraulic elevators in a loft and office building. The surge tank of the system was in an out-of-the-way place under the floor. The awful groan drove the whole lot of us almost to distraction, including about 50 or 60 dressmakers on the fifth floor, and they threatened to quit. Of course, that would never do.

We located the groaning in the water end, and began feeding it soap suds, cylinder oil and graphite, etc., without satisfactory results, so we decided to operate. It was found that the two bronze plungers and the cast bronze sleeves (a snug fit) were cutting badly and something had to be done. We painted the plungers with graphite and cylinder oil, then went on a still hunt for the cause of the cutting and found the water in the cistern full of grit, scum, lath, lime, sand and cement that would neither sink nor float on top, but would stay suspended in the water. There was no provision made for emptying the cistern, but we soon had an ejector at work and had the cistern empty and thoroughly cleaned; after filling it with fresh clear water, we had no more trouble. R. A. **Perry.**

Hayden, Ariz.

Why a Different Rate of Scale Formation?

I have picked up much useful information from *Power*, and by way of return I am sending the following on a subject I have never seen discussed, in the hope of stimulating investigation which may be well worth time and money to follow up.

As a boiler inspector I have often been struck by the different amounts of scale to be found in boilers using the same water and working under the same conditions, and on inquiry I find other inspectors have noticed the same thing, but without thinking further about it. Two cases in point are as follows: Of two locomotives made by the same firm, working at the same pressure, fed from the same water supply and working the same number of hours, one boiler shows practically no scale and the other is in a very bad condition with scale. In a battery of boilers all working under similar conditions as regards pressure, feed supply and time between each cleaning, one boiler has much less scale than any of the others, yet the man whose duty it is to look after the feed tells me that judging by the amount of water he puts into it, it must evaporate about twice the quantity of steam the others do.

I could cite many other similar cases, but these two are enough to show what is meant. My idea is that there is something in the composition of the plate which accounts for it. If this is correct, the task would be to find out what that something is and then to see that all future boilers were made with this material. Perhaps some readers may be able to confirm my statement.

Wigan, Lancashire, England. A. **Bennett.**

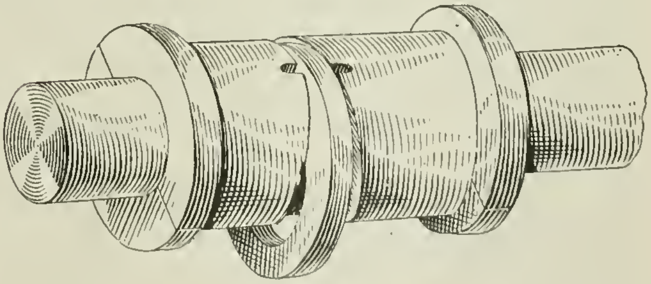
Keeping Lubricator Glass Clear

To keep cylinder oil from coming in contact with and adhering to the sight-feed glass of a lubricator, my practice is to insert a small strand of copper wire in the tube. This wire should extend to the top of the sight glass, but care should be taken not to have it so long as to come in contact with the top plug when it is screwed in. M. H. **Osgood.**

Woburn, Mass.

Improvement in Ring Oilers

The slot in the top half of ring-oiled bearings is sometimes made too wide for the ring and the oil is not carried to the oil grooves and consequently is not properly distributed. On the high-pressure end of turbines the heat from the casing and the steam makes the use of a heavy oil almost imperative, as the lighter oils are "boiled out" of the reservoirs. A good grade of steam-cylinder oil follows up the oiling ring in a thicker film, but this necessitates a wider ring slot at the bottom, as shown in the illustration. I make it a rule to increase the width of the slot at the bottom to twice that of the top and find it a great improvement.



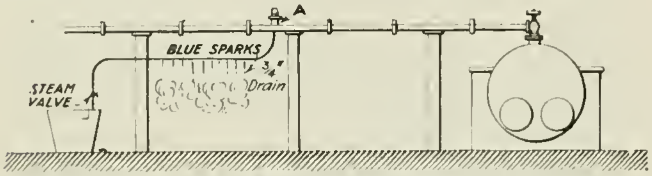
OIL-RING SLOT MADE WIDER AT BOTTOM

In using heavy oil, start the turbine slowly and give the oil time to get thoroughly warm and flowing freely.

Herkimer, N. Y. **Harold G. Burrill.**

An Electrical Phenomenon

At the close of my apprenticeship days, many years ago, I had a peculiar experience never since observed, although it is said not to be unusual. It manifested itself in a curious manner and in such a way as might easily give a man of nervous temperament a shock not soon to be forgotten. I was at that period engaged upon the upkeep of the works plant which included, among other things, a 9 x 30-ft. Lancashire boiler carrying 150 lb. pressure and situated some distance from the works at the end of a field, where a new power house was to be erected. Steam was sent across the field through an 8-in. pipe supported about seven feet above ground to supply the existing works engines, and at a point *A* about midway in the line there was a branch taken vertically and then horizontally at right angles to the main pipe line across to another part of the works, where other engines were situated.



PIPE LINE WITH BLEEDER PIPE THAT BURST

At the base of the tee there was a $\frac{3}{4}$-in. pipe attached to act as a drain and also to feed a tank for boiling suds. It was the custom to shut the steam off this pipe line at night and turn it on again early in the morning. On this particular morning in January, during a spell of extremely "black frosty" weather, on starting up it was found that the $\frac{3}{4}$-in. drain pipe had frozen solid during the night, and it had to be allowed time to thaw out, which occurred about 6:30 a.m., but the frost had split it all along one length of pipe so that after it had thawed out, steam issued from the split into the cold air of the early morning with a high velocity and a tremendously shrill noise. This in itself was not so alarming, but the phenomena accompanying it presented a startling appearance, for, at a distance of about three inches from the split seam, and at that point where the steam began to show itself expanding into a visible vapor, there was a steady stream of heavy blue sparks having a comb-like appearance, apparently jumping across the air space from the pipe to the vapor, the effect being accentuated by a crackling noise not unlike continuous musketry firing at a distance.

When called to my attention, I naturally experienced an uncanny feeling, intensified by the frightened tones of my informant, but soon decided what the cause was. The blue sparks were discharges of static electricity produced by the friction of dry steam slightly superheated passing through cold dry air at a high velocity. Upon closer examination the discharge was found to be taking place actually where the expansion of steam was visible. Detailed information will be found in textbooks treating of electricity and magnetism regarding such phenomenon.

Such electrical effects are also met with by engineers in other forms. A fireman vowed that he got a shock upon touching the mechanical stokers, and it was found to be caused by the dry driving belt running at a high velocity, for upon holding the hand near the inner side of the belt a thick bluish spark leaped across the air space from the belt to the hand, giving the experimenter a sharp but not dangerous shock.

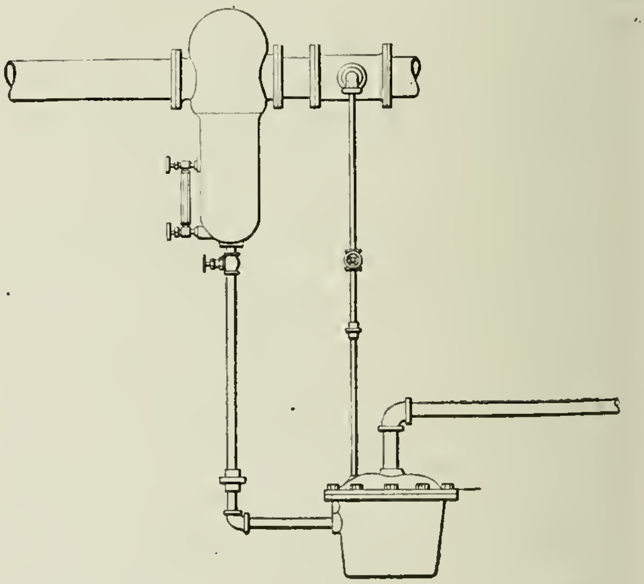
Electrical effects of this nature are met with in paper making. Paper is passed from the wet stage onto steam-heated revolving cylinders, then put through heavy calendering rolls so as to glaze the surface somewhat. This last process creates a static discharge, with its crackling noise, tending to distort the paper as it is being wound on to rolls. To prevent this distortion, a crude but satisfactory method is adopted; that is, two or three pails of water are placed upon a plank, spanning the machine, vertically over the point of exit of the paper from the rolls, and into each pail is inserted some loose strands of cotton rope or other material hanging well down below the bottom of the pails. The capillary action of these wick siphons is sufficient to distribute drops of water at regular periods into the air space between the paper and rolls, which is enough to dissipate the electrical discharge.

Doubtless other engineers know of many such instances, but perhaps under different conditions.

London, N. W., England. **Henry S. Whiteley.**

Trapping Water from Air Line

In a plant furnishing compressed air for various processes of manufacturing, a great deal of complaint was occasioned by the moisture in the air, especially during damp weather. A separator "helped some," but there was difficulty in trapping the water from the separator and it was necessary to leave a small drip or bleeder open all the time, as the trap did not work right; consequently, there was considerable loss of air at times and at other times the water would accumulate faster than the bleeder could take care of it. The difficulty with the trap was caused by its becoming air-bound, so the engineer drilled, tapped and connected it as shown in the illustration, with the air main allowing the air to flow back to the main, and no further difficulty was experienced. **C. W. Oakley.**



TRAP CONNECTED TO SEPARATOR ON AIR LINE

Passaic, N. J.

Inquiries of General Interest

Strength of Manila Rope—What is the breaking strength of ½-in., ¾-in., 1-in. and 1¼-in. diameter Manila rope? I. P.

New well-laid Manila hemp rope, ½-in. diameter, should have an ultimate strength of at least 1900 lb.; ¾-in., 4100 lb.; 1-in., 7100 lb.; and 1¼-in., 10,900 lb. But for ordinary uses the working stress of ½-in. diameter rope should not exceed 50 lb.; of ¾-in., 112 lb.; of 1-in., 200 lb.; and of 1¼-in., 312 lb. Greater working stresses cause the rope to rapidly deteriorate in texture and strength.

Grate Openings for Smaller Size of Coal—For using a smaller size of coal with forced draft we are using the herringbone grate bars with ⅜-in. openings formerly used for burning buckwheat size of coal, and considerable trouble is experienced from coal falling through the grates after each cleaning. What size of grate openings should be used? E. T.

The smallest slot form of openings practicable for ordinary forced draft are ⅛ to 3/16 in. wide. By first spreading the grates with the coarsest fuel that is retained in cleaning, a minimum amount of fresh fuel will drop through.

Steam Consumption and Weight of Feed Water—In stating steam consumption in pounds, is this calculated from the number of pounds of feed water evaporated? B. C. M.

Unless otherwise qualified, steam consumption stated in pounds refers to the weight of dry saturated steam supplied at some particular pressure. Computation of the weight consumed can be made from known weight of feed water that has been evaporated and supplied as steam with deduction of the percentage of moisture in the steam delivered or of the percentage of moisture above the stipulated percentage. The weight is only to be considered identical with the weight of the boiler-feed water when the steam is delivered as dry saturated steam or if it is superheated or it has the specified percentage of moisture.

Cost of Coal per 1000 Cu.Ft. of Steam Generated—Where the actual evaporation of a boiler is 8 lb. of water per pound of coal into steam at 100 lb. gage pressure and the cost of the coal is $8 per ton of 2000 lb., what is the cost of coal per 1000 cu.ft. of steam generated? H. L. Y.

The cost of coal would be $8 ÷ (2000 × 8) = $0.0005, or 1/20 of 1c. per pound of steam generated. Assuming that the feed water is converted into dry saturated steam at a pressure of 100 lb. gage or 115 lb. per sq.in. absolute, then, according to the Marks and Davis Steam Tables, the density of the steam or weight per cubic foot would be 0.2577 lb. Therefore 1000 cu.ft. would weigh 1000 × 0.2577 = 257.7 lb., and the cost of coal required would be 257.7 × $0.0005 = $0.12885, or practically 13c. per 1000 cu.ft. of steam generated.

Space Occupied by Coal—How many cubic feet should be allowed per ton of coal? W. E. T.

The weight per cubic foot and consequently the number of cubic feet per ton varies with size, and uniformity of size to which the coal is broken, and also depends upon whether the coal is "shaken down" in bulk as by transportation and on the specific gravity of the coal, which varies for different mines and for coal taken from different parts of the same mine. Hence there is considerable variation in the cubic feet per ton, and further confusion arises from misunderstanding of whether "long" tons of 2240 lb. or "short" tons of 2000 lb. are under consideration. The average weight of American anthracite, taken in boxes holding 2 cu.ft., has been quoted as 53.4 lb. per cu.ft. and of Maryland and Pennsylvania bituminous coal as averaging 52.8 lb. per cu.ft., from which a short ton of anthracite would occupy 2000 ÷ 53.4 = 37.45 cu.ft. and a long ton 2240 ÷ 53.4 = 41.94 cu.ft.; and a short ton of bituminous coal would occupy 2000 ÷ 52.8 = 37.87 cu.ft. and a long ton 2240 ÷ 52.8 = 42.42 cu.ft. On account of the wide variation of conditions, no estimates of weight of coal from measurements of bulk should be regarded as more nearly approximate than within about 10 per cent. To be on the safe side, provision for space for storage of coal should allow not less than about 40 cu.ft. per ton of 2000 lb. and 45 cu.ft. per ton of 2240 pounds.

Relative Efficiency of Copper and Iron Heating Surfaces—What is the relative efficiency of coils made of iron or of copper tubes for heating water by a gas flame? F. M. E.

Copper coils are more durable than coils made of iron or steel pipe, and while the material is bright and clean the rate of transmission of heat to the water is several times as rapid as with new iron or steel pipes of the same size and arrangement. But coils of copper heated by gas quickly become coated with a deposit from the products of combustion that renders the copper surfaces no more efficient than similar iron-pipe heating surfaces that have been in use for the same length of time. Tests of two fire-tube boilers made alike, excepting that one had iron fire tubes and the other copper fire tubes, showed that their evaporative activity was practically the same.

Explanation of Formula for Use with Throttling Calorimeter—What is the explanation of the formula for determining the fraction of dryness of steam with the throttling calorimeter? A. L.

So far as practical results are concerned, the steam in the throttling calorimeter contains the same number of heat units per pound as the steam in the pipe from which the sample is taken; and since the original steam contains more heat per pound than necessary for dry saturated steam at the low pressure in the calorimeter the latter is superheated; that is, contains more heat per pound and is of a higher temperature than if it were dry saturated steam at the low pressure.

The specific heat or heat required to raise one pound of superheated steam through one degree when near the pressure of the atmosphere is commonly taken as 0.48 B.t.u. per pound, hence if t_2 is the temperature indicated by the thermometer and t_1 is the temperature of dry saturated steam given by the steam tables for the pressure existing in the calorimeter, then the steam is superheated $(t_2 - t_1)$ degrees and the B.t.u. absorbed as superheat by each pound of steam would be $0.48\ (t_2 - t_1)$. Hence if $H =$ the total heat of a pound of dry saturated steam at the pressure that exists in the calorimeter, then the number of B.t.u. contained by each pound of the steam in the calorimeter would be $H + 0.48\ (t_2 - t_1)$, and this same quantity of heat is assumed to be present in each pound of the initial steam. The whole of each pound of the original water must have been heated to the boiling point while only a fraction of a pound may have received the latent heat of evaporation. Hence, if for a pound of the initial steam $h =$ the heat of the liquid, $L =$ the latent heat of evaporation, and $q =$ the fraction of the whole pound that is dry saturated steam, then for a pound of the initial steam the B.t.u. present would be $h + qL$, and as the heat per pound of the initial steam is assumed to be the same as the heat per pound of the steam in the calorimeter, then

$$h + qL = H + 0.48\ (t_2 - t_1), \text{ or } q = \frac{H + 0.48\ (t_2 - t_1) - h}{L}$$

Storage and Weathering of Coal*

By W. D. STUCKENBERG and J. F. KOHOUT
Commercial Testing and Engineering Co., Chicago

During the present international complications the storage of coal is becoming increasingly necessary. The prime purpose, of course, is to have a supply of fuel on hand so that plants will not be shut down and homes will not be without heat. Another reason is the occasional, at the present almost universal, lack of railroad equipment to move the coal from its source to the ultimate destination. Labor troubles also interfere with the production or handling of coal, either at the mine, in transit, or in the cities.

ONE OF the theories now being advanced for the relief of railroad congestion and mine running time is to require large consumers, who are under annual contracts, to accept their coal in equal monthly shipments. This practice, if instituted, will necessitate storing coal when the deliveries are in excess of daily demands. The storage thus accumulated will have to be used at times when shipments are less than daily consumption.

Broadly speaking, the larger sizes of coal from about No. 3 nut on up through the various sizes of nut, egg and lump store without giving any trouble. This is due to the fact that these sizes are drier and offer a smaller surface, in proportion to their mass, to the action of oxygen than do the finer sizes.

Anthracite and semibituminous coals store well in any size, but this is probably due to their chemical composition. Oxidation occurs here also, but is much slower in action, and, therefore, smaller in amount for any given length of time. Sub-bituminous coal from the West, frequently called black lignite, is hardly suitable for storage. Its tendency to slake condemns it.

Finer Sizes High in Moisture and Iron Pyrites

The finer sizes of coal, which are used principally for power purposes, are generally high in moisture and iron pyrites. These are deleterious ingredients because of the ease of oxidation of the pyrite in the presence of water vapor. The finer sizes, that is, coal passing through 2-in. screen and smaller, expose a great number of small surfaces to the air. These several factors all tend to initiate oxidation and to speed it along once it has started.

Here also the difference between Eastern and Western coals should be explained. The former are much purer in that they are low in moisture and pyrite. The Western coals are much higher in both of these constituents and are therefore to be considered as being much more liable to spontaneous ignition. As an illustration of this peculiarity, a quantity of screenings from southeastern Kentucky was in storage for seven years, but when it was moved there was no visible evidence of excessive oxidation or deterioration. On the other hand, a storage pile of western Kentucky screenings may fire easily within 60 days.

Storage piles vary in size from a few tons to many hundred thousand tons. This fact necessitates a careful consideration of the three methods of storage—under water, in closed bins and in open piles. Under water any kind and size of coal may be kept for any length of time without danger from fire. This method is used by large consumers who also hold coal in open piles for immediate use. Storage in closed bins is generally limited to small quantities of fuel.

The great bulk of storage coal at present is kept in open piles. It is intended to be held readily available for use, and is seldom on the ground for more than a few months. As a matter of fact, it should not be kept long, but the length of time should depend on the kind of coal, since this is the most dangerous form of storage. However, when proper precautions are taken at the time the coal is placed on the ground and maintained while the pile lasts, losses may be eliminated or reduced to a minimum.

The losses which occur may be considered to be due to oxidation. It should be borne in mind that the rate of oxidation increases with the temperature, also that coal is a poor conductor of heat, so that much of the heat occurring or generated in the interior of the pile stays there. These two facts indicate that when oxidation starts, even though at a low temperature, it generates a small amount of heat. This heat is insulated from the outside air and, being retained, tends to increase the rate of oxidation. This one action helps the other, and the oxidation proceeds at a constantly accelerated rate, the more easily oxidizable compounds or constituents being attacked first.

Iron pyrite is oxidized in the presence of water to ferrous sulphate and sulphuric acid according to the equation expressed in plain English,

Iron pyrite + oxygen + water = Iron sulphate + sulphuric acid + heat.

This reaction takes place with a considerable evolution of heat. It is true that the oxidation really goes farther with the evolution of still more heat, but this additional heat, and also the heat due to the action of sulphuric acid on lime or alkalies present in the coal, or the heat generated by the dilution of the acid with water, are not considered. It must be remembered that the water actually enters into chemical combination with the pyrite and oxygen, unless the water is present in sufficient amount to exclude the air. This is the condition that prevails in under-water storage and is one of the reasons why that method is best.

When coal is stored in the dry state, the equation for the oxidation of the pyrite previously given is incomplete, since the moisture component is absent. When it is stored under water, the equation is again incomplete, because the air is thus excluded and the oxygen component is absent.

In other words, the oxidation of coal in the dry state proceeds very slowly, since the only moisture available is that in the coal and in the air. In dry coal the moisture is very low, so in dry storage one of the necessary constituents of the reaction is lacking to a relatively large extent.

In several instances which have come under observation a low-volatile coal, called "Arkansas semi-anthracite," has given considerable trouble from spontaneous combustion. This coal has a fairly large content of sulphur and low moisture. Its principal use has been as a substitute for semibituminous or Pocahontas coal for domestic use; and when it is unloaded from wagons into basements, it is generally sprinkled with a garden hose to lay the dust. This supplies the moisture which is necessary for the oxidation. Several fires have occurred in Chicago from this cause, and the fact that the coal is used so much in dwellings makes extreme care in its storage and handling absolutely necessary. It has not been on the Chicago market long enough to demonstrate if it would heat up in the dry state, but theoretically it should give no trouble in such a condition.

How the Temperature of the Pile Is Raised

The heat due to the oxidation of pyrite, helped by that coming from external sources, if any, raises the temperature of the pile to the point where the carbon and hydrogen of the coal begin to be attacked. This action is aided by the fact that coal, particularly when freshly mined, has a strong affinity for oxygen. The oxygen is absorbed much as water is taken up by a sponge. This supplies the oxygen needed for the oxidation of the carbon and hydrogen. The action is not likely to occur until a temperature of about 250 deg. F. is reached. The temperature of the coal is raised by these processes until it reaches a point (about 450 deg. F.) where the action is autogenous and is no longer dependent upon external sources of heat to maintain

---

*Excerpt from paper read before the Kentucky Ice Manufacturers' Association.

the temperature. When the temperature mounts up to about 750 deg. F., the coal takes fire.

Paradoxical as it may seem, the fact must be kept in mind that small amounts of moisture assist in the oxidation of the coal. This was tested out by Professor Parr at the University of Illinois. His bulletin No. 46, "The Spontaneous Combustion of Coal," giving the results of his experiments, shows without exception, in all the series of tests, that the wetting of the coal increased the activity, as shown by the ultimate temperature. Thus, when a storage pile is burning, it must be flooded with water to extinguish. Merely wetting the surface or outer layers of coal with a hose or spray will hasten the loss.

Heat from External Sources

In connection with piles of coal in storage, the effect of external sources of heat is of extreme importance. Without the aid of heat from some external source, the initial stages of oxidation either would not occur or their rate would be extremely slow. These sources may be steam pipes in the ground or near the pile, as in conduits, etc., which are in contact with the coal, or the heat from boilers. This last is particularly true in the case of bunkers on vessels. In one case that came under observation, a pile of coal which ordinarily stores without trouble, ignited. The cause was finally discovered in the presence of a manhole covered with a thin layer of earth, and so overlooked, through which steam passed. This manhole was immediately under the pile of coal and was the means of supplying enough heat to start the oxidation of this coal.

When coal is unloaded by dumping on the ground from a car or a high trestle and then is piled up to almost the level of the car floor, as is frequently done in the coalyards, the heat of impact and of pressure constitutes a positive danger to the coal.

The question is often asked as to the best season of the year to store coal. As far as possible coal should be placed on the ground in the winter months. It is then cold and fairly dry. The heat of impact and pressure, due to unloading and piling, while present, will not raise the temperature of the coal to any noticeable degree, and certainly not to the temperature of ordinary summer weather. Of course the coal must be free as possible from snow and must be unloaded on an area from which the snow has been carefully removed. One plan worked out for a consumer was to put down about two or three months' supply in September, October and November, then when the first of January came around to pick up this storage and let the daily shipments be put down for the fresh storage to be used in the spring, when labor troubles would disturb production.

Absorption of Sun's Heat

Absorption of heat from the sun will also raise the temperature of the coal to a surprising degree. This was noticed particularly at a plant in Chicago that was receiving coal direct from a mine in Indiana. The coal carried a rather large amount of moisture and pyrite, but was taken out of the ground only about ten days before delivery. When received, it was so warm that the hand could not be kept in contact with it for more than a few seconds. The reason for this was discovered in the fact that it was shipped in steel cars which stood on sidings exposed to the direct rays of the sun for about two days. The steel absorbed the heat readily and so raised the temperature of the coal. If this coal, instead of being passed directly to the furnace, had been placed in storage in the condition in which it was received, undoubtedly it would have fired spontaneously in a short time.

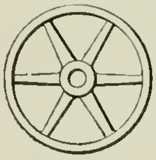
Oxidation or weathering of coal decreases the heat value. The loss is brought about by the oxidation of carbon and hydrogen to carbonic acid and water, which escape as gases. There is also an increase in weight of the coal due to the absorption of oxygen. This oxygen replaces combustible matter and acts like so much ash. In fact, the United States Bureau of Mines has shown in Bulletin No. 29, "The Effect of Oxygen in Coal," that oxygen and ash are of very nearly equal anticalorific value. Oxygen also interferes with the coking quality of coal, and a coal that has weathered to any great extent has either entirely lost its coking quality or at any rate will make coke of inferior quality. In addition, coal will disintegrate under the influence of oxygen, and the larger pieces will break up. In fact, the recommendation has been made that coal a size larger than that ordinarily burned at the partricular plant should be stored, so that when the storage coal is burned it will not be too fine for use.

This discussion of the effects of oxidation leads to a consideration of some of the precautions to be taken to prevent or minimize them. One scheme used in this connection had the opposite result. This consisted of two perforated pipes placed down in the pile. The idea evidently was to ventilate the interior and to provide for the escape of heat, should it be generated. However, one of the pipes, which happened to be about two feet higher than the other, acted as a stack, while the lower pipe served as an intake for fresh air. The odor of coal gas and of the products of combustion was clearly perceptible at the top of the higher pipe. Thus what was intended to check combustion was really furthering the oxidation of the coal. To minimize oxidation the following precautions should be taken:

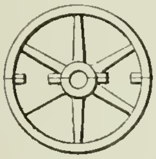
1. Avoid external sources of heat that may in any way contribute toward increasing the temperature of the mass of the coal.
2. Eliminate coal dust and fine coal as far as possible.
3. Store dry coal and keep it dry.
4. Put the coal on the ground in a dry, clean place on as clear and cool a day as possible.
5. Do not pile the coal too high. Shallow piles afford the best chance for the escape of heat from the interior.
6. Store as large a size of coal as possible.
7. Store under water if possible and be sure the coal is completely submerged.
8. Watch the interior temperature of the pile with a thermometer, and as soon as any abnormal rise in temperature occurs, mark that spot as the next one to be drawn on for fuel, or if the conditions seem serious, overhaul the pile at that point and flood it.

Safe Speed for Cast-Iron Flywheels

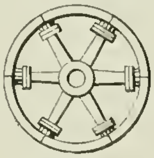
The following table of safety speeds for cast-iron flywheels has been prepared by William H. Boehm and published in the *Operative Miller*. The margin of safety at the speed given is considered to be approximately three:



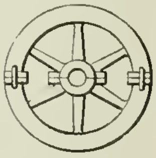
No Joint
100 Per Cent.



Flange Joint
25 Per Cent.



Pad Joint
50 Per Cent.



Link Joint
60 Per Cent

TYPES OF WHEELS AND THEIR MAXIMUM EFFICIENCY

Diameter in Ft.	R.P.M.	R.P.M.	R.P.M.	R.P.M
1	1,910	955	1,350	1,480
2	955	407	675	740
3	637	318	450	493
4	478	239	338	370
5	382	191	270	296
6	318	159	225	247
7	273	136	193	212
8	239	119	169	185
9	212	106	150	164
10	191	96	135	148
11	174	87	123	135
12	159	80	113	124
13	147	73	104	114
14	136	68	96	105
15	128	64	90	99
16	120	60	84	92
17	112	56	79	87
18	106	53	75	82
19	100	50	71	78
20	95	48	68	74
21	91	46	65	70
22	87	44	62	67
23	84	42	59	64
24	80	40	56	62
25	76	38	54	59
26	74	37	52	57
27	71	35	50	55
28	68	34	48	53
29	66	33	47	51
30	64	32	45	49

If the revolutions given in the table be increased 20 per cent., the margin of safety on speed will be reduced to two and one-half; if the revolutions be increased 50 per cent., the margin of safety will be reduced to two.

Hydro-Electric Development*

THE introduction of electricity as a means for transmitting power over considerable distances and its subsequent rapid development completely changed the status of hydraulic power. Previously, such power could be used only near falling water. Now it is commercially available in convenient form within a radius, in some instances, up to 200 miles, a fact that has made it possible to utilize water powers even when located in remote and inaccessible places. Indeed, today practically all hydraulic-power developments of any magnitude are hydro-electric.

In the light of the foregoing it might seem reasonable to suppose that a large proportion of the modern demand for electric current would be supplied from the energy in falling water. Such, however, is not the case. Accurate statistics are difficult to obtain, but some approximate totals may prove illuminating. It has been estimated by a careful engineer that in 1911 there were over 26,000,000 steam-engine horsepower capacity in use (including railroad locomotives) in the United States. The aggregate water horsepower developed and undeveloped has been computed as around 60,000,000. Of this latter the United States Census of 1912 gives 4,870,000 as developed, and in a report of January, 1916, the Secretary of Agriculture estimates this total to have been increased to 6,500,000. Making liberal allowances for correction in these several figures, it seems probable that there are in service from four to five times as many steam as water horsepower and that there are still undeveloped water horsepower equal to at least twice that of all the steam capacity in service.

Steam- and Hydro-Electric Power Compared

There are two fundamental causes which have militated against the substitution of hydro-electric for steam-electric power. One is economic and permanent; the other is statutory and therefore subject to modification. Both reasons apply to some powers, but neither, fortunately, to all. The economic and permanent reason is high cost of development due to natural conditions. Electric power generated by falling water is inferior to that generated by steam in every particular except cost, and therefore water-driven service must be cheaper than steam-driven in order to justify its existence. The price for service depends primarily on cost, and cost divides itself naturally into two main items, namely, operation (including maintenance) and fixed charges. As a hydro-electric plant consumes no fuel, its operating cost is less than that of an equivalent steam-driven plant. On the other hand a steam plant costs usually only from one-fifth to one-half as much per unit of capacity as a hydro-electric plant, so that the latter must carry very much heavier fixed charges.

This disability of water service is usually even greater than the ratio of the costs of two equivalent complete developments. When steam is to be the motive power, only such capacity is installed as initial demands require, and the cost per unit is fairly proportional to that of the ultimate development. In a water development, a large part of the cost is for riparian rights, for the dam, flume, forebay, etc., and for the transmission right-of-way, towers, etc., which must be at the start largely provided and constructed for the complete installation. The obvious result is a greater fixed charge per unit of capacity and a higher cost per horsepower delivered for sale.

In forecasting the commercial prospects of a power enterprise, the possible market must be studied and, of course, a sale price for power decided upon. As this price is controlled by the cost of similar service from other sources, usually from steam, and as it must be attractive from the start, the additional burden of fixed charges on the initial part of a hydro-electric installation frequently forces the sale of its power below cost. The projectors of the enterprise then must rely for success on a sufficient subsequent increase in their markets. The possibility of an incorrect forecast of the extent of such increase and of the time when it may come imposes a serious business hazard against water and in favor of steam.

It has been frequently pointed out that as the nation's coal supply is depleted, the cost of coal must rise, thus increasing the cost of steam-electric power as a competitor and raising the market value of hydro-electric power accordingly. The rising price of coal is a matter of record, but it is not so generally known that the improved efficiency of boilers, engines, generators and auxiliaries has more than kept pace, so that the net cost of producing electric power from coal has steadily declined.

Factors That Influence the Cost of Power

There is nothing to indicate that the limit of improvement in the design of steam prime movers has been reached or is even in sight. It is, therefore, a reasonable assumption that further advances in the art will continue to occur and to cut down both the fixed charges and the operating cost of steam power as a competitor of water. As bearing on the water-power situation, obviously many sites which fifteen years ago might have been developed to sell energy in successful competition with steam at its then cost could not now be so developed, and in consequence their development is no longer commercially possible.

The cost of producing power from either water or steam is a function of load. Fixed charges remain practically unchanged in both instances, whether the output in energy be large or small; but with a steam plant, increased output means increased fuel consumption, while a water plant operates either with or without load with but little variation in expense. To illustrate by a concrete example representing not unusual conditions, suppose we assume a steam plant using 2½ lb. of coal per kilowatt-hour at a price of $3 per short ton and having a plant or output factor of 35 per cent.—that is to say, an output equal to 35 per cent. of its theoretical output if every unit were loaded to capacity 24 hours each day of the year. Under these assumptions the cost of fuel per unit of installed capacity per year would be $11.50, and if the other operating and maintenance charges be assumed to fairly offset those of a water installation of equivalent size, $11.50 represents the additional fixed charges which the hydro-electric plant could carry and produce power at an equal cost. If the fixed charges (interest, taxes, insurance and amortization) total 11½ per cent., therefore, the hydro-electric investment per kilowatt capacity could exceed that of steam by $100. This is not an abnormal excess. Many hydro-electric developments exceed the cost of equivalent steam-driven systems by much greater amounts, in which cases they become commercial prospects only if either coal be more expensive per unit of output, or the plant factor be higher, or some other operating or maintenance condition be more favorable.

Inferiority of Hydro-Electric Power

As has been previously stated, hydro-electric power is inferior to steam-electric power. The reasons are elementary. Stream flow is subject to seasonal variation, and therefore to complete or partial interruption by drought in summer and by ice in winter. Floods are a menace. Long transmission lines may break from wind or sleet or the service be disarranged by lightning. The losses on such lines vary with load and are frequently responsible for annoying pressure variations. On account of these and other reasons, hydro-electric power cannot prevail against steam competition at the same or a slightly lower price. It must be materially lower.

We do not mean to imply that water power may not be a commercially practicable competitor of steam. Many successful hydro-electric installations give substantial proof to the contrary. We do wish most emphatically to combat, however, the widely held but mistaken view that any water-driven plant will produce power at lower cost than steam can, and that the margin is so large investors generally

---

*Excerpts from a statement prepared and presented on the special invitation of the Water Power Committee of the United States Chamber of Commerce, by the Executive Committee of Engineering Council of the United Engineering Society.

are eagerly seeking a chance to put money into hydro-electric projects. The most careful investigation, frequently demanding substantial expenditure and the keenest scrutiny by experts, is needed to discriminate between worthy and commercially impractical projects, and the difference is often so small that the imposition of even what seem to be minor burdens is sufficient to turn the scale in favor of steam and entirely prevent what might otherwise be a desirable hydro-electric development.

The second condition which vitally affects development is statutory. After ten years or more of discussion it has come to be generally agreed that our Federal laws discourage the development of a large proportion of the nation's water powers, and remedial legislation has been considered at every session of Congress for many years. The legal obstacles are quite distinct and separate from the economic facts which have been previously described and are in addition thereto.

Of the estimated 55,000,000 undeveloped water horsepower in the entire country, approximately 40,000,000 is within the boundaries of the thirteen so-called Western water-power states. In these same states the Federal Government still retains as proprietor 760,000,000 acres, or over two-thirds of the aggregate acreage of all these states taken together. In order to develop power in that section it is therefore nearly always necessary to use some part of this public domain, if not for the dam site itself, at least for flowage, for transmission right-of-way or for some other purpose. Existing law forbids such use except under permit issued by the Secretary of the Interior and revocable without cause, at any time, by himself or his successor in office.

It was once believed that revocation would only follow gross abuse well established by evidence; but the drastic action of a one-time Secretary of the Interior some years since to the contrary disabused investors of this confidence and demonstrated by a sad object lesson the insecure tenure afforded by existing law. As funds for hydro-electric development must come from private sources, the unstable tenure imposed by this condition has constituted so great a hazard of loss that the private investor has been loath to assume it. The unfortunate—almost disastrous—result has been practical stagnation in water-power development for many years.

Many available power sites not in the Western States, or not on the public domain, are on navigable streams. For each such project a special act of Congress is necessary. The difficulty of obtaining suitable rights by this means has been found so very great as largely to discourage, even if not entirely to prevent, the developments affected.

It should be pointed out that a hydro-electric enterprise being once successfully established, it is alike to the interest of the owners of the Government and of the public that it should continue indefinitely without interruption. There is no economic reason to be served by a cessation, and the only reasons for providing a legal means of recapturing the installation and the water rights are to preserve an additional measure of Government control against possible abuse by the permittee, and to provide for a contingency which might make it desirable that the Government would want to use the power for some other purpose.

In nearly all cases steam plants are necessary to supplement hydro-electric power at periods of low water and in case of interruption, as well as, in some instances, to provide increased capacity. In fact, modern practice is rapidly approaching that of providing steam capacity equal to 100 per cent. of hydro-electric for the purposes stated. In any event the growth of the enterprise over a term of years will be continuous and progressive. There will never come a time when it may be said to have been completed and subject to no further expansion. This continuing growth makes burdensome and usually abortive any attempt to amortize the investment, while the investment in other water powers or in steam plants or both, interconnected with, and generally dependent for their economic operation on, the original development renders the right to recapture that development very onerous and one which constitutes a serious impediment to the free and full development of an enterprise which is otherwise most desirable from all viewpoints.

With respect to power sites on the public domain and on navigable streams, the Government is in the position of seeking to have its resources developed without assuming any business hazard and without contributing either capital or credit. It would be unfortunate, in the light of past experience, if any new laws which may be enacted should put the Government in the position of bargaining with capital and of offering just sufficient incentive not to induce capital to undertake the developments desired, thereby, while apparently providing a remedy, in reality insuring a continuance of the present undesirable condition.

It is our belief that the benefits afforded the communities served by cheap power, and to the nation by the conservation of coal resulting from the substitution of a self-renewing for a nonrenewable natural resource are far more valuable than is the exact solution of the question of restricting the returns to capital to their irreducible minimum. The present emergency due to the progress of the war has forcibly illustrated the importance of having developed the greatest possible number of water powers as a source of industrial power supply. As it consumes no fuel, the substitution of water for steam power would release to other uses all the extensive railroad and water facilities now engaged in transporting coal. It would similarly release a corresponding volume of labor now occupied in mining this coal and in operating such transportation agencies as well as the boiler-room forces of the steam-power plants themselves.

What We Do and Don't Know About Heating[*]

BY PROF. JOHN R. ALLEN

THERE are many things we know about heating and I will try to enumerate the principal ones; there are many things we don't know about heating, but *can* know if we would take the time and the money necessary to investigate. There are also many things that we will never know, because the problem involves too many variables which can never be solved.

Let us start first by considering the laws of heat. Most of the useful experiments that can be immediately applied to heating were first made by Peclet in 1840 to 1850. Peclet's work was translated into English by Box about 1880 and is given in Box's "Treatise on Heat." Almost every author since Box's time has quoted Box and given Box's constants for radiation, conduction and convection. Some authors have given him credit, but most authors seem to have forgotten the source of their information.

In recent years very little fundamental work has been done by physicists upon heat and its application. The modern physicist is wedded to electricity, and he can tell you the electrical resistance of iridium and titanium and all the metals that are never used for electrical conduction, but he cannot tell you the heat resistance of a brick or a piece of stone, or a piece of concrete. There is a real reason for this. Heat is extremely difficult to experiment with accurately and electricity is the easiest of all the fields of research. If electricity is in its infancy, as is often said, heating is in embryo and unborn. We know a thousand things about electricity to one that we know about heat.

Has anyone ever looked up the various authors to find the constants for radiation, conduction and convection? If so, he would have found results varying as much as 100 per cent. There is an opportunity for some physicist to make himself undyingly famous by establishing beyond controversy some of these much-used constants. It is this lack of fundamental knowledge that has hampered and is still hampering the heating engineer in dealing with the heat problems connected with his business. This lack of fundamental knowledge has affected all our experimental work. We make small experiments through a very narrow range of observation on very special devices, and these experiments would be absolutely unnecessary had we the fundamental principles underlying these devices.

Of the fundamental laws we probably know a little about conduction, still less about convection and very little about radiation. We find the statement made in physics that a dull-black surface radiates the most heat. In my own experiments upon cast-iron radiators I found that there was practically no difference in heat transmission between dull-black and pure-white polished surfaces. In fact the pure-white polished surface gave off about 3 per cent. more heat than the dull-black. These are facts that my physicist friends have never been able to explain.

HEAT LOSS FROM BUILDINGS

Consider heat losses from buildings. For years we guessed at them by some rule-of-thumb. These rules were usually proposed by someone supposed to know more about heat than anyone else and were usually very dangerous to apply throughout a wide range of conditions.

We have followed the German, the theory of which is generally considered to be at least approximately correct, but these formulas require certain practical constants for heat transmission. The heat laboratory at Charlottenburg has determined many of these constants for German forms of building construction, but very little work has been done in this country. Some years ago I started to check up the German constant for glass, which of course is the most fundamental constant that we have. I found that for dry glass with no rain or wind the constant $K = 0.64$; for rain and no wind, $K = 1.248$; for wind and no rain, $K = 1.05$; for rain and wind, $K = 1.485$. The generally accepted constant by authors as determined by the German government is 1.3 and for fifteen years we have accepted this constant. It is entirely possible to have the glass surface wet even in zero weather and the constant is manifestly too small. Personally I am now using $K = 1.25$ as the glass constant. This only goes to show that some of our fundamental facts are wrong and need a careful checking up.

When it comes to the constant K for cement, hollow tile, metal lath and similar construction, practically all the constants we have are based upon computation—they are only approximate. They may be right; they are probably wrong or largely in error, and we have no experimental work to guide us. We need in this country a vast amount of experimental research so as to place these fundamental constants of the heating business on a well-established foundation.

INFILTRATION AND RADIATION

One of the important factors in determining the heat loss from a building is the amount of air that leaks in around the cracks and crevices. One of the first assumptions with respect to infiltration was made by Carpenter, in which he assumed that the air in a room was changed once per hour due to infusion of air from outside or infiltration. In the average room this is approximately true. On the other hand, there is absolutely no reason why the cubic contents should have anything to do with infiltration, as infiltration occurs largely around the windows and window frames, and it should be based on wall and window conditions and not upon cubic contents. Recent experiments in New York show that, particularly in metal sash, infiltration should be based upon the perimeter of the sash.

Of course, there is one factor in this that we will never know, as no one can foresee how tight or how loose the contractor is going to construct the building. The equation of the contractor has never been determined, and considering the number of variables entering into the problem, it never will be determined. Such phases of our computations will always have to be covered by adding a certain percentage which might well be called the "factor of ignorance."

We have much more explicit information in regard to radiation than in regard to heat loss from buildings. We know that a two-column 38-in. radiator will give a value of K of about 1.65 B.t.u. with 1 lb. steam pressure and a room temperature of 70 deg. We know that this constant K increases as the difference between the temperature outside the radiator and the temperature inside the radiator increases. The approximate formula is:

$$K = 1.445 + 0.001437 \ (T_1 - T_2)$$

where T_1 = the temperature of the steam and T_2 = the temperature of the room.

We know something about the painting of radiators. If a radiator is painted with any kind of flake metal pigment, such as aluminum, gold or bronze, its efficiency is reduced approximately 25 per cent. If it is painted right over the aluminum with an enamel, the heat transmission is the same as the bare iron. I have made these experiments with 14 coats of paint on the radiator and the effect of the last coat was practically the same as that of the first coat.

This shows that the heat transmission of the radiator depends upon the ability of the surface to dispose of the heat and not upon the conductivity of the material of which the radiator is composed. That is, under the conditions existing in a radiator, the heat is transmitted much more rapidly through the metal of the radiator than the surface of the radiator can dissipate the heat. It is possible that we may find some coating which can be placed upon a radiator that will increase its conductivity beyond that of the bare iron. I do not know that any attempts have ever been made to do this, but it is one possible means of increasing radiator efficiency.

A radiator gives off heat in two ways—by radiation and by convection. For many years I have tried to find out what proportion of the heat is given off by radiation and what proportion by convection. Approximately it is "50-50," but I have never been able to make a satisfactory determination. This is impossible as undoubtedly some of the radiant heat from the radiator passes directly out through the wall and window surface without having any effect, and we may find it desirable to so arrange our radiators that all heat given off by them is given off by convection. We should have more fundamental knowledge on this subject.

Take the indirect radiation, and by indirect radiation I mean that not only through which air circulates by natural circulation, but through which air circulates by means of a

---

[*] A paper presented at the annual meeting of the American Society of Heating and Ventilating Engineers, New York City, Jan. 23, 1918.

fan or of fan coils. We know that in this type of radiator all the heat from the radiator is given off by convection and in convection the form of the surface plays a very important part in its effectiveness. We also know, and recent experiments prove, that effectiveness of its surface is practically independent of the material of which the surface is composed. Copper, cast iron and wrought iron give practically the same effect.

The condensation from surfaces of this kind depends upon the air resistance of the radiator, provided the radiator is properly designed. That all depends upon the temperature of the surface and the temperature of the air. Since the condensation depends upon the air resistance of the radiator, in radiators of this class low resistance is not wanted because in order to get the condensation, it will be necessary to put in a number of radiators. Some engineers have specified widely spaced fan coils of low resistance and then put in a bank of coils in order to obtain condensation. This is simply wasting surface, as the same heating effect could be produced with closely-spaced coils and a much smaller number of them.

Determining Pipe Sizes

In this country we probably give less consideration to pipe sizes than in any other engineering country. The sins committed by the average contractor in the matter of pipe sizes are legion. When we get down to the economical use of pipe there is just one way to determine the sizes and that is to determine the resistance of each piece of pipe. We design good fan piping systems for air by resistance and yet we design our steam-piping sizes on a heating job by guesswork and experience—these terms are sometimes synonymous.

Some years ago, when I had some time on my hands and a heating plant was to be designed, I designed a real piping job and figured the pipe resistance to each radiator, and it is the most satisfactory job of heating that I ever installed. The average engineer, however, is too lazy to go to the trouble of doing this, and I am just as guilty as the rest.

To take pipe sizes out of a table and have them determined by the square feet of radiation is no basis of reason on a large job. It is quite possible that close to the boiler you can put 150 sq.ft. of radiation on a 1¼-in. riser, while at a remote point a 1¼-in. riser might carry only 60 sq.ft. A tremendous amount of pipe is wasted in the heating business by using excessive sizes. To design a system of this kind requires great accuracy but gives economical results.

The modern piping system in a steam-heating installation always reminds me of a small pumping station I once inspected. The board of directors had purchased a pump with a 2-in. discharge, and they instructed the engineer to run the 2-in. pipe from the pump a distance of three-quarters of a mile. When I came to examine the pipe I found that the pump was working against a static head of 70 lb. and friction head of 100 lb., and that in place of a 2-in. pipe they should have had a 6-in. pipe when the calculations were based on friction.

In the heating business, however, we more often make the mistake of using pipe too large rather than pipe too small, particularly in the smaller installations. In hot-water piping with forced circulation it is absolutely necessary to work from friction, if uniform circulation and no short-circuiting is expected.

Pipe Coverings

We have some very good information upon the subject of pipe coverings above ground. We are just acquiring a little information in regard to pipe coverings below ground. I have been making some experiments on pipes buried in the ground without any covering. The surprising thing in these experiments is the great distance that heat is transmitted through the ground. It is possible to detect a steam pipe under ground twenty feet away.

We also find that the condensation below ground is less than the condensation in the air. Our latest experiments show that there is less condensation with the steam passing through the pipe at a good velocity than with the steam in a quiescent state in the pipe. Of course, the deeper the pipe is buried in the ground the less is the heat transmission, and if we were to bury a pipe to a sufficient depth it would be unnecessary to have any covering at all—the ground would serve as its own heat insulator, so that the deeper we run heating ducts and heating pipes the less we need insulation. This fact is often lost sight of. Exact data in regard to these facts are not available, but as a number of experiments are being carried on we undoubtedly will soon be able to make some exact statements.

Every heating engineer seems to have an ambition to invent some new heating device that everyone will have to use and that incidentally will give him an opportunity to make some money. There have been placed upon the market and advertised, thousands and thousands of heating devices. Some of them are very good, some do no harm when placed upon the heating plant, and some are positively detrimental. Some are very good when properly applied and are useless under other conditions.

Some years ago I installed a heating plant in a residence, and the plant is almost identical with a certain patented system of heating now on the market. The only difference between my system and the patented one is that I left off all the patented articles and my system, I think, works a little better than similar near-by systems that used the patented articles.

We must always remember as engineers that the best design is always the simplest. There is a tendency among all engineers in the heating business to complicate their systems—to use too many unnecessary devices. This is largely due to the fact that these devices have been urged upon them by salesmen who must secure business. Many of these devices are very meritorious, but the attempt is to give them universal application when they should only be applied in specific cases.

The purpose of these remarks has been to emphasize:

1. The necessity of bringing to the attention of physicists and scientific men the fact that we need more knowledge of the science of heat and heat transmission. As we get more and more exact knowledge, this knowledge should be used by the engineer so as to leave less to experience and guesswork and more to actual figures. It will never be possible, however, in heating work to entirely eliminate the factor of judgment. So many variables enter into the problem, such as the conditions of building construction and the materials used, that we will always have to make our figures only the basis for our judgment.

2. To call the attention of engineers to the tendency to overload the plants with unnecessary devices and to urge the greatest simplicity in construction and the economical use of materials. The present high prices of piping and materials should lead us to consider every possible means of conserving these materials.

Cost Plus a Fair (?) Profit

Fuel-oil prices are discussed in a special bulletin issued Jan. 27 by the Federal Trade Commission, showing wide variation between the cost of oil plus refining and the sale price, particularly in the East and Middle West.

The figures are based on August reports of the refiners. The commission notes that published quotations show that prices now are from 70 to 104 per cent. higher than they were in June. Following are the August figures in cents for "representative cost," refining charge and sale price at district centers:

	Cost Crude	Refining	Cost Refined	Selling Price	Percentage Profit
New Jersey and Eastern Territory (Pittsburgh)..	$3.34	$0.94	$4.28	$8.00	87
Indiana and North Mississippi Valley (Chicago)	2.04	.47	2.51	5.75	129
Oklahoma (Tulsa)........	1.85	.58	2.43	3.60	48
Gulf Coast (Ft. Worth)..	2.14	.33	2.47	4.00	62
California Coast (San Francisco)........	1.96	29	2.25	3.45	53

The selling prices given were those at the district centers named in the first column.

Appointment of Ordnance Draftsmen

The Bureau of Ordnance, Navy Department, is in need of competent draftsmen. Men who are graduates in mechanical engineering from a technical school or college of recognized standing and have had some drafting-room experience, or men who are competent designers of heavy machinery, engines or shop tools, and have had a number of years' drafting-room experience, are eligible for these positions. The pay ranges from $4 to $6.88 a day, depending upon the qualifications of the draftsman.

There are now a number of vacancies in the rating of draftsman at the Washington Navy Yard. Additional information may be had by addressing the Commandant and Superintendent, Naval Gun Factory, Navy Yard, Washington, D. C.

Labor in Its Relation to National Efficiency

Until within a month the most discouraging fact to those looking on in Washington was the lack of any indication of broad consideration of the labor problem. The President's speech before the American Federation of Labor put up no constructive policy. It was a patriotic appeal. The Department of Labor was dealing with industrial disputes as they arose, but there was no expression of fundamentals. The direct parties to the controversy—employers and employees—were pulling apart instead of being drawn together. Apparently, as far as official Washington was concerned, we were to be allowed to come to an *impasse* without any effort on the part of the Government to compromise the difficulties.

Within two weeks there has been a most remarkable and a most welcome change. Today machinery is in motion which will bring the contending interests together on a broad basis. Light has broken. Hope has succeeded the discouragement of last month.

The first official recognition of the need for a broad consideration of the problem was the appointment of an Advisory Council to the Secretary of Labor. This appointment—far more important, broadly speaking, than many of the problems that have occupied front-page space—was hardly noticed in the public prints. Yet that council is expected to determine the policy that shall keep labor and capital working together during the war. More than this, if their work is far-seeing—as the constitution of the council gives warrant for expecting—it should have a tremendous, if not the determining, influence on the socio-economic conditions under which we shall live after the war. To industry, therefore—yes, and to labor, to the country at large—the establishment of the council is easily the most important event since the beginning of the war.

Lest this estimate of the importance of the council be considered extravagant, it will be well to set down here the work outlined for it. It will consider the establishment, in the Department of Labor, of agencies to perform the following functions:

1. A means of furnishing an adequate and stable supply of labor to war industries. This would embrace: (a) a satisfactory system of labor exchanges; (b) a satisfactory method and administration of training of workers; (c) an agency for determining priorities of labor demand; (d) agencies for dilution of skilled labor as and when needed.

2. Machinery that will provide for the immediate and equitable adjustment of disputes in accordance with the principles to be agreed upon between labor and capital and without stoppage of work. Such machinery would deal with demands concerning wages, hours, shop conditions, etc.

3. Machinery for safeguarding conditions of labor in the production of war essentials—this to include industrial hygiene, safety, woman and child labor, etc.

4. Machinery for safeguarding conditions of living, including housing, transportation, etc.

5. Fact-gathering body to assemble and present data collected through various existing Governmental agencies or by independent research to furnish the information necessary for effective executive action.

6. Publicity and educational division, which has the function of developing sound public sentiment, securing an exchange of information between departments of labor administration and promotion in industrial plants of local machinery helpful in carrying out the national labor program.

The first four divisions cover matters familiar to all manufacturers, contractors and engineers. Subdivisions (b), (c) and (d) of function (1) represent activities made necessary by the war. The true significance of the establishment of the body is appreciated when attention is directed to the sixth division, and when we recall the activities of the labor division of the British Ministry of Munitions and the influence that its work, of the same broad scope, has had on industrial England. What can one not read into "the function of developing sound public sentiment" and "promotion in industrial plants of local machinery helpful in carrying out the national labor program"? such program obviously being comprehended in the determination of the first four divisions of the program. One may expect that the "developing of a sound public sentiment" will necessitate the statement of the fundamentals for industrial and labor prosperity—a difficult task, but one the performance of which would be of the greatest value.

If further evidence is needed as to the possible influence of the council, it is furnished by its action last week in recommending to the Secretary of Labor (1) the organization of a board which will formulate an arrangement for ending strikes and (2) the centralization in his department of the industrial service divisions of the various branches of the war machine. Both plans have been approved by the secretary. The first of them is absolutely essential if coöperation is to replace strife.

The personnel of the council, as has been said, gives warrant for expecting broad-gaged results. It is headed by John Lind, former governor of Minnesota and envoy to Mexico, representing the public; Waddill Catchings, president of the Sloss-Sheffield Steel and Iron Co. and of the Platt Iron Works; and A. A. Landon, general manager of the American Radiator Co., representing the employers. Labor's members are John B. Lennon, treasurer of the American Federation of Labor, and John J. Casey, former member of Congress. Dr. L. C. Marshall, of the University of Chicago, is the economist member, and Agnes Nestor, of Chicago, represents women.

The council's duty is not merely to formulate a program, but to recommend the machinery for putting it into effect. That it believes in action is shown by its two public acts within ten days after its organization. Industrial leaders will be impressed by that evidence of virility and will follow closely the further activities of the body.—*E. J. Mehren, in Engineering News-Record.*

Work of the Labor Divisions of War Administration Co-ordinated

Upon the recommendation of the Advisory Council created to report on the handling of industrial relations growing out of the war, the Secretary of Labor has arranged for the coördination of the industrial service (labor) activities being developed in the various purchasing and supervisory offices of the war administration. Simultaneously, a number of new bureaus have been established and will assume the coördinating functions.

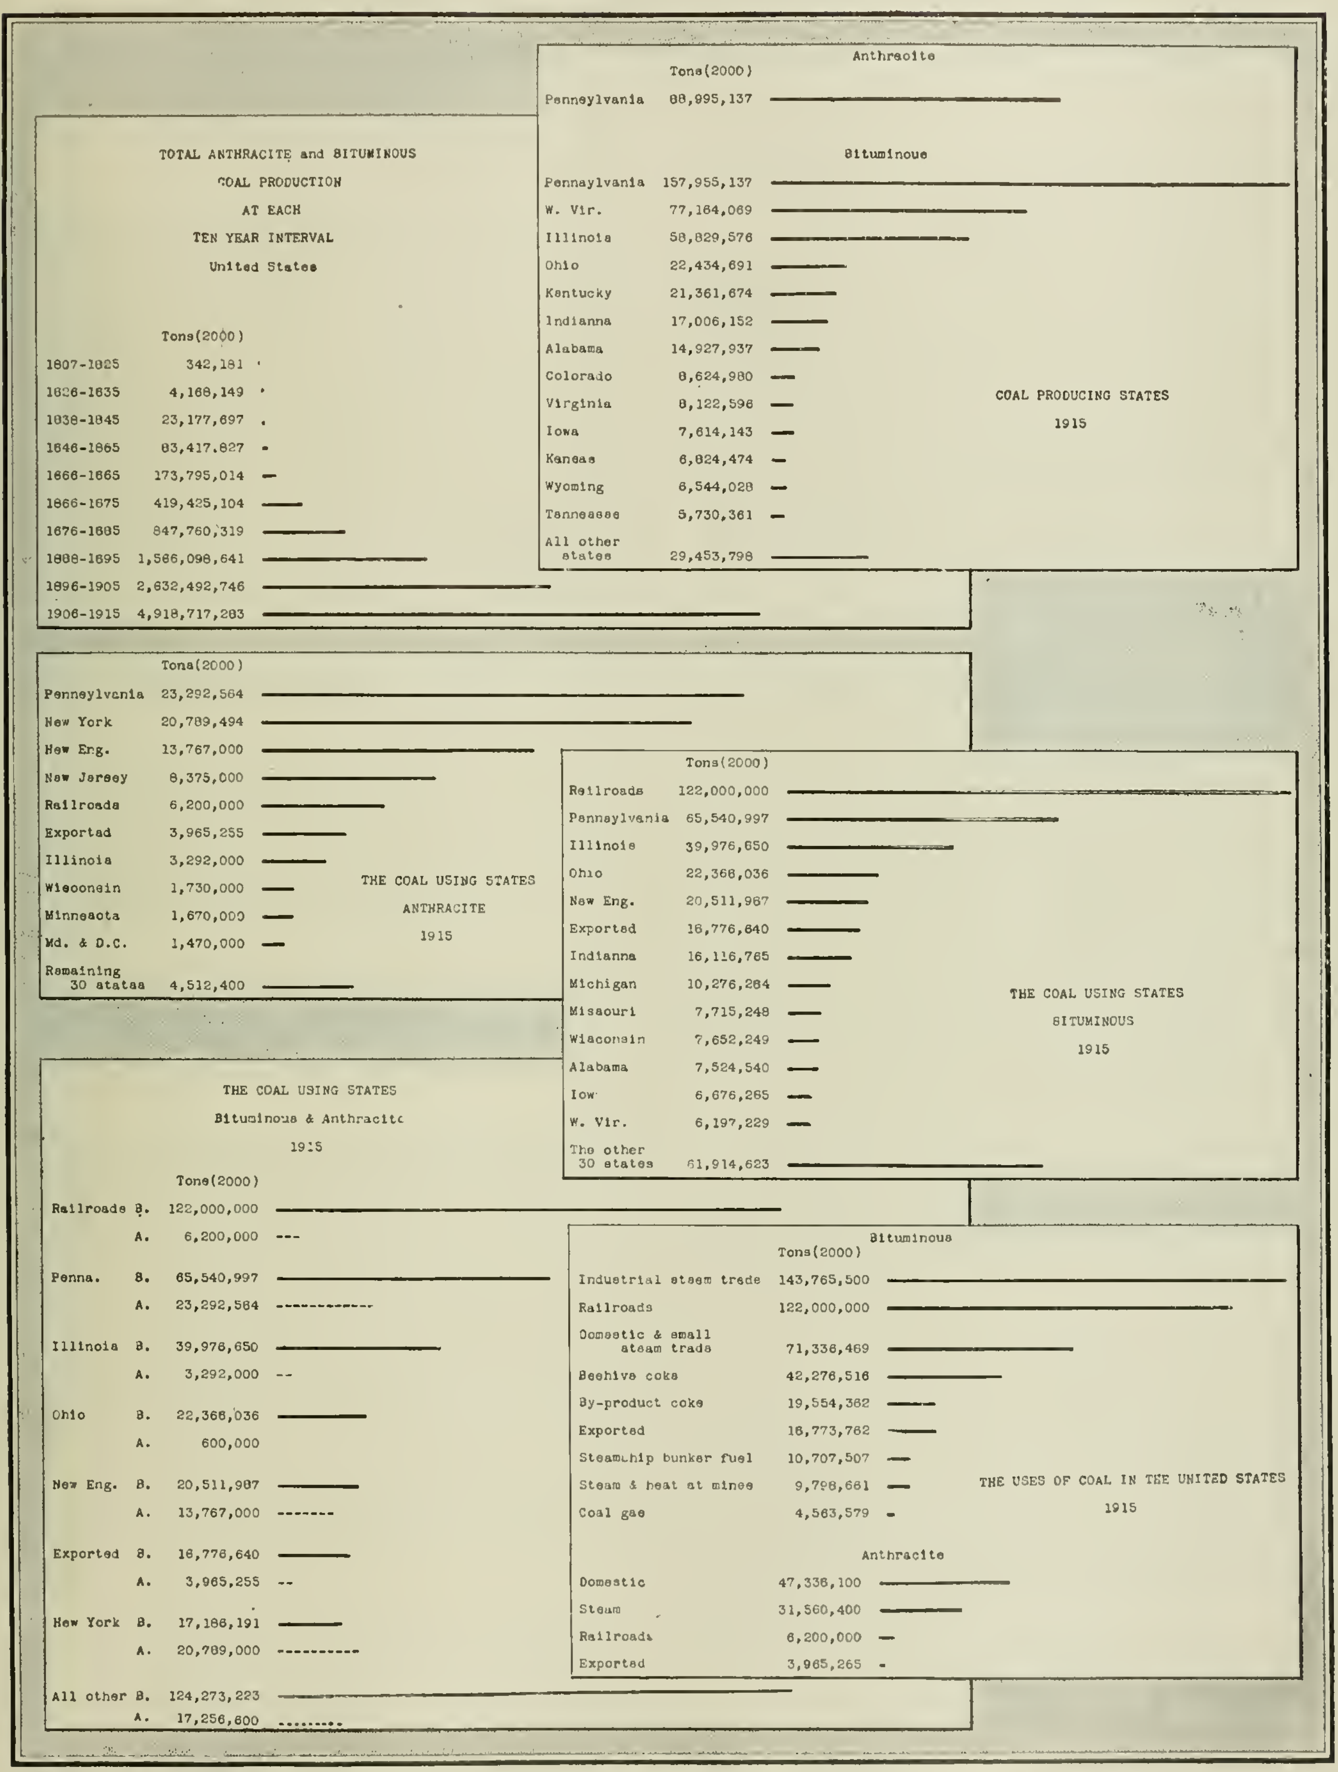
A well-developed industrial service division is in operation in the Ordnance Department, and similar organizations are being worked up in the other purchasing and supervisory branches of the War Department as well as in the Navy Department and the Shipping Board. These bodies are all developing plans for accomplishing similar results in their own given departments. In some cases they might, if not coördinated, work to cross purposes, and in any of their activities exchange of views on methods is desirable. The necessary machinery for getting together is now provided by the action of the Secretary of Labor.

The following new bureaus are established to effect the desired coördination: (1) Adjustment Bureau, to deal with disputes; (2) Condition of Labor Bureau, to administer conditions of labor within business plants, such as safety, sanitation, etc.; (3) information and Education Bureau, to promote sound sentiment and to provide appropriate local machinery and policies in individual plants; (4) Women in Industry Bureau, to correlate the activities of various agencies dealing with this matter; (5) Training and Dilution Bureau; (6) Bureau of Housing and Transportation of Workers; (7) Bureau of Personnel (which may possibly be fused with the Information and Education Bureau).

The present United States Employment Service will act as the coördinating bureau on the procurement of labor.

In a theater, hall or other densely filled room, the body heat given off by the occupants must be considered. This averages 425 B.t.u. per hour per person. After the building is once warm, thoroughly heated and the performance has started, it is more a problem of cooling than of heating, and it is the ventilation which is of prime importance.—*B. F. Sturtevant Engineering Series.*

Production and Uses of Coal in the United States



The above tables, with graphical representations of coal production in the United States and of consumption for the year 1915, were presented by Prof. L. P. Breckenridge at the recent meeting of the American Society of Heating and Ventilating Engineers.

The total production shown for the ten-year period 1906-15 would give an average annual production of 491,871,728 short tons. For 1916 the total production in the United States was 590,098,175 short tons, and for 1917 it was increased to 633,401 789 short tons.

Points in Steam-Boiler Management*

BY C. E. STROMEYER†

Some points relating to the safe and economical operation of steam boilers, obtained from the experience of an association which has been engaged for over fifty years in the prevention of boiler explosions by scientific inspection.

An EFFECT of the war conditions is the scarcity of labor and its replacement by substitutes. As a rule boiler attendants of former days, if engaged from outside, will have had varied boiler experiences, or if they were advanced from the position of laborers, they will have been selected on account of their reliable disposition and will have received some training. It is a mistake to imagine that boiler attendants should think that they are competent to judge of the safety of boilers. Their first and foremost qualification should be reliability. In fact, the little knowledge which can be imparted to them may be or, rather, often has been a dangerous thing. A fireman who has been taught to believe that it is dangerous, especially to himself, to overload the safety valve or to allow the water level to sink out of sight is safer than a man who has heard that a boiler is worked at a factor of safety of four or five and overloads the safety valve or who knows that the gage-glass bottom is 3 in. or 5 in. above the furnace crown and, once too often, allows the water level to fall out of sight.

There are, of course, many good men among the substitutes and many willing men who wish to do their best. They show their willingness by working hard, but a busy stoker is rarely a good one. A stoker's limited duty is to shovel coal on the fire, watch the pressure gage and water level, and manipulate the feed valve. A man who is new to his job is probably at first not impressed with the importance of these matters. Not until he discovers that the works actually engage an inspector to carefully examine the inside of the boiler, to adjust the safety and low-water alarm valves, and to verify the pressure and water gages, does he become impressed with the importance of these matters and of his own duties.

SUBSTITUTES FREQUENTLY REDUCE EFFICIENCY

Another effect of having to employ substitutes in place of well-tried stokers is that the efficiency as well as the output of boilers is very frequently reduced. This is particularly annoying at the present time, when coal is both scarce and dear and increasing demands are made on boilers. Take the case of a boiler that used to be fired with good coal by an expert fireman. Possibly the duty of such a boiler might have been increased 10 per cent. without a reduction of efficiency. If, however, the demand for steam has increased 10 per cent., if the quality of the coal has been reduced, and if an inexperienced stoker has been engaged, the probability is that he will not be able to maintain steam, he will rake and slice his fires and reduce the efficiency by perhaps 10 per cent., and the boiler, which is probably unable to increase its consumption by 20 per cent., wastes coal and reduces its steam production.

It seems desirable to discuss the suggestion that managers should set aside a day or two to the study of the firing problem, and devote themselves to the teaching, or rather guiding, of the newly appointed fireman. If, as may easily be the case, especially with the present high coal prices, such a procedure should result in a saving, the time and trouble will have been well spent.

Seeing that the best teachers are said to be those who are learning while teaching, the owner or his manager who watches the stoking operation need not imagine that his is a case of the blind leading the blind. The leading principles are exceedingly simple and are based on what is transparently obvious, that the maximum quantity of steam is produced from a ton of coal if the heat losses are reduced to a minimum.

The man who may be watching the fireman will soon discover that the more quickly the firing is done the more easily can steam be maintained, but only if the firing is properly done. Suppose that the coal is thrown on the grate anyhow; then, as there is less resistance to the passage of air at the thin parts than at the thick ones, the latter hardly burn away at all, while the former burn themselves first into pockets and then into holes, and long before the next firing is done there will be a rush of cold air through these holes. This unfavorable condition has, of course, to be remedied by raking, but that operation introduces cold air and results in a diminished steam production and a reduced efficiency.

It would, however, be wrong to forbid the raking of the fires or the opening of the doors. Some coals must be broken up, and some coals, because they produce smoke, must be supplied with air through the doors. This latter air supply has to be regulated by studying the smoke discharged from the chimney. If it is black or dark, then the air supply through the fire-door is insufficient; if there is no smoke, then there is an excess of air either through the door or through holes in the bed of fuel or through the bed of fuel if this is too thin.

HOW TO FIRE DIFFERENT QUALITIES OF COAL

As some of the preceding remarks apply only to smoke-producing coal, a few words on the firing of different qualities will be needed. Roughly speaking, coals can be divided into caking and noncaking coals. The latter break up while burning, and if disturbed by raking, they fall through the grates and the result is much waste. Coal of this class should therefore be thrown evenly on the grate and should not be disturbed. Considerable manual skill and a good eye are required to do this work properly, and inexperienced firemen will have to use the rake.

Caking coal, on the other hand, must be broken up after it has become heated and stuck together. Caking coal produces smoke, and that has to be avoided. The general practice with this coal is therefore to throw it on the front end of the grate, nearly choking the fire-door hole, which is kept open during the time that the mass of coal is warming up and producing smoke and combustible gases. Then this mass of coal is broken up with a rake and shoved back, the fire-door being entirely or partly closed some time after. Another method, called side firing, is equally effective in preventing smoke. The firing interval of, say, fifteen minutes is divided into two short ones of about seven minutes, and during the one opening of the door the fuel is thrown only on the one side of the grate, and during the next on the other side. The smoke which is produced on the newly charged side is consumed as it passes to the other side. If this firing were done with the help of long troughs filled with coal, in the same way that horizontal gas retorts are charged, the periods during which the fire-doors are open could be very much curtailed and the efficiency of the furnaces improved.

INSPECTION AND CLEANING OF FLUES NECESSARY

Bad results are, however, not always due to the fireman; in many cases the inspection and cleaning of flues is not properly carried out. In a certain factory the power requirements had increased somewhat, and on account of bad coal and poor firemen the steam production sank lower and lower and the coal consumption rose higher and higher. On the advice of an outsider, which advice seemed reasonable under the existing conditions, a sixth boiler was added to the five overworked ones. Then the trouble grew

---

*Excerpts from "Memorandum by Chief Engineer" of the Manchester Steam Users' Association.

†Chief engineer, Manchester Steam Users' Association.

worse; even more coal was burnt, and less steam was produced. Several people were asked to give advice, and we too were appealed to. On examining the various dimensions it was found that the flue area was only suitable for three boilers, and as alterations could easily be made, we recommended the building of a larger flue. It was also discovered that there was a solid layer of flue dust, which must have been damp occasionally, of two feet in thickness. The factory can now be worked with the greatest ease with five boilers, and the saving of coal is probably well over $5000 per annum.

A source of recurring trouble is the disturbance of the brickwork of the flues and outer walls. It is an almost daily occurrence that our inspectors draw attention to these and similar defects in the flues and thus help to maintain the efficiency. That these disturbances should occur is but natural, for the difference in length of a boiler when cold and when hot is about half an inch, and as it is a heavy weight, it is sure to pull the brickwork about. These expansions and contractions also affect the outer walls, which crack and admit air, and this unnecessary air wastes much heat. As these cracks may occur the day after an inspection, it is desirable to look for them and have them plastered up. Searching along the walls with lamp or candle flames is not an efficient method. A simpler plan is to have the boiler walls, especially the front and the blowoff pit, whitewashed as frequently as may be found necessary. If any cracks occur, the inrushing air, laden with coal dust, will blacken the cracks, and these can then be plastered up and whitewashed.

In continuation of my analysis of the Board of Trade reports on boiler explosions, those accidents which were due to wasting of shell plates have now been taken in hand. The analysis embraces 75 reports. The general conclusion to be drawn from these practical cases, and it is an important one, is that when wrought iron plates are very materially reduced in thickness by corrosion, their tenacity is also reduced to about one-third of its original value.

In plotting these 75 explosions against the years in which they occurred, it appears as if the prospect of the early passing of the Factory and Workshops Act, with its compulsory inspection clauses, had frightened many careless owners into having their neglected boilers examined. At any rate, whereas before 1900 there were on an average three explosions per annum due to shell wasting, from that date the average number was reduced to one.

Men Wanted for Shipyard Work

The Department of Labor is seeking to enroll 250,000 men for work in shipyards. A nation-wide campaign began Jan. 28 with an appeal to all men possessing any skill in any of the trades necessary to the building of ships to enroll as a reserve supply of labor sufficient to meet present and future needs of the shipyards. Some of the men enrolled will be called upon at once, others as they are needed. Men who enroll themselves will not sacrifice independence of action, and are advised to remain at their present jobs until notified that places in shipyards are open to them. The "four-minute men" will conduct a speaking campaign in every state.

Following is the quota for each state: Maine, 2972; New Hampshire, 1698; Vermont, 1390; Massachusetts, 14,321; Rhode Island, 2355; Connecticut, 4786; New York, 39,526; New Jersey, 11,348; Pennsylvania, 32,771; Ohio, 19,802; Indiana, 10,847; Illinois, 23,662; Michigan, 11,734; Wisconsin, 9611; Minnesota, 8762; Iowa, 8531; Missouri, 11,812; North Dakota, 2548; South Dakota, 2393; Nebraska, 4400; Kansas, 6330; Delaware, 811; Maryland, 5250; Virginia, 8453; West Virginia, 5327; North Carolina, 9264; South Carolina, 6253; Georgia, 11,001; Florida, 3435; Kentucky, 8260; Tennessee, 7952; Alabama, 8994; Mississippi, 7488; Arkansas, 6022; Louisiana, 7064; Oklahoma, 8492; Texas, 17,023; Montana, 1583; Idaho, 1621; Wyoming, 618; Colorado, 3320; New Mexico, 1428; Arizona, 888; Utah, 1660; Nevada, 386; Washington, 5906; Oregon, 3204; California, 11,310.

The American Engineer*

The American engineer is that citizen of the United States who is qualified by training and practice to join with his coworkers to direct organizations and harness natural resources which will crush the greatest menace to Christianity and make the world safe for democracy.

He is the man who will after this war solve the great international problems of making all countries safe and sanitary for their peoples.

He is the man who has for his foundation a broad engineering education that has prepared him to use the natural elements which he has discovered and developed through experiment until today the Atlantic and the Pacific are speedways; the air is a highway free from dust and the shortest distance between two points for travel, and a line for conversation by telegraph and telephone; the swamps are the best fields for grain; and the hills and mountains are producing untold wealth.

He is the man who recommends the expenditures of millions by his government or by the business men of the country. All industry, either in war or peace, depends upon the engineer for production and operation. Our profession is extremely fortunate to have the opportunity to step in and be the deciding factor in the war which will mean most to civilization for all ages.

The American engineer is the man of the hour.

Would Utilize Peat

Governor McCall of Massachusetts has sent a message to the legislature, saying in part: "I recommend that you make an investigation of uses of peat, the near-by deposits, the methods of its utilization in producing heat and power, and in other ways with a view to enacting such legislation relating to it as your investigation may show to be for the public interest. Peat has long been used as fuel in different countries, and I am informed that at present it is utilized in Germany in the production of heat and power, in munitions of war and even in clothing, through use of its fiber. I am advised that large deposits exist in New England, and that even under existing methods of preparation much of it may be made available for power and heat before the coming of another winter.

"Its large content of ammonia would tend to relieve scarcity of that article, much needed now in the making of munitions and invaluable at all times for use in agriculture. We are largely dependent on coal for heating our homes and keeping our industries in motion. If we have on hand in great quantities a substance which may make us less dependent upon coal, it is our obvious duty to take steps for its development. I believe the subject well worth immediate investigation by you either through a regular or special committee or in some other way, and that a moderate appropriation be granted to make the investigation effective."—*Boston News Bureau.*

Ecuador and Peru Favor American Electrical Goods

America's opportunity of increasing its sales of electrical goods in Ecuador and Peru during the absence of German competition is pointed out in a report made public by the Bureau of Foreign and Domestic Commerce, of the Department of Commerce. Before the war this trade was divided between Germany and the United States, the advantage being with the American manufacturer. The Government's report is concerned with the market as it exists today and the opportunities it offers for the future.

Copies of "Electrical Goods in Ecuador and Peru," Special Agents Series No. 154, can be purchased at the nominal price of 10c. from the Superintendent of Documents, Government Printing Office, Washington, D. C., or from any of the district or coöperative offices of the Bureau of Foreign and Domestic Commerce.

---

*From address given before the Savannah Chapter of the American Association of Engineers, Saturday, Jan. 26, by A. H. Krom, general secretary, American Association of Engineers.

Firing Bituminous Coal in Heating Boilers

Technical Paper 180, "Firing Bituminous Coals in Large House-Heating Boilers," by S. B. Flagg, Bureau of Mines, tells how to burn bituminous coals economically in these large house-heating boilers.

In burning bituminous coals in large house-heating boilers the fuel bed should not be seriously disturbed until the coal has become well coked; that is, until the gassy part of the coal has been largely driven off.

Both caking and noncaking types of coal may be used satisfactorily in boilers of this type if properly handled.

The presence of a moderate proportion of screenings mixed with the lump coal causes the fresh charge of coal to heat more gradually and the emission of smoke is kept down more easily. Therefore such a proportion of screenings is an advantage.

Increasing the proportion of screenings in the coal necessitates the use of a stronger draft to carry the same load. Smaller firing charges must also be used and more frequent attention given. The tendency of caking coals to cake is increased and this also means that the fire must have more frequent attention.

One large charge of coal fired by the spreading method will result in a longer emission of dense smoke than the total emission of such smoke from two charges of half the size fired some time apart and by the alternate method.

With some coals moderate charges fired by the alternate method necessitate less frequent attention to the heater than larger charges fired by the spreading method. Caking coals having a considerable proportion of fine coal or screenings are usually among these. Conversely, a fire will usually require more frequent attention when a lumpy caking coal free from screenings or a noncaking coal is fired in moderate charges by the alternate method.

The number of tests made was not large enough to justify conclusions regarding the relative efficiency with which a coal may be burned by the two methods of firing, but the author believes that in actual service over considerable periods better results will be obtained by the alternate method.

Frequency of cleaning the fires will be determined by the character of the coal and the rate at which it is burned, but with most coals the fires should be cleaned only once or twice in 24 hours in ordinary weather.

If the alternate method of firing is employed, the cleaning should be done just before firing the fresh charge, and only one-half of the grate cleaned at a time. Then little or no smoke will result from the cleaning, because the side of the fire on which there is uncoked coal is not disturbed.

All three of the coals fired by the alternate method in the tests described were burned at rates corresponding to the heating conditions during the most of the winter, with scarcely any manipulation of the fuel bed except the cleaning of the fires and an occasional leveling just before firing.

The average fireman is apt to poke and slice the fire much more than is necessary. If a caking coal is used and the caked fuel must be broken up before it is well coked, slice the fire by running a straight bar under the fuel bed and raising it slightly so as to crack the caked mass. Do not stir the bed upside down by raising the bar through the fuel bed, nor break the bed with a bar from the top.

If the fuel bed is covered with a charge of fresh fuel in a layer more than 5 in. thick, the new charge, unless it is very free from slack, is likely to have a smothering effect. Then the output of the boiler will be correspondingly decreased and, especially if the spreading method of firing is employed, the mass of fresh coal will usually have to be broken once or twice before the fire will pick up. Consequently, the maximum firing charge should be not much thicker than five inches and for caking coal containing considerable slack it should not be more than four inches thick. Of course, when a fire is to be kept banked, heavier charges may be used.

Do not fire large lumps of coal. Break all lumps into pieces no larger than fist size.

Large house-heating boilers do not require an intense draft to meet any reasonable demands for heat if the fuel bed is kept in proper condition, but the draft must be properly controlled.

The damper regulator should work freely with changes in steam pressure and should close the swinging damper in the ashpit door before it starts to open the check damper in the smoke pipe.

The doors on the front of the boiler should fit snugly in their seats; special care should be taken to prevent any material wedging between the doors and the front and thus admitting air when or where it ought to be prevented from entering.

Do not allow clinkers to accumulate in the fire or too great a quantity of ashes on the grates. Be careful, however, in shaking the grates not to shake through unburned fuel.

In ordinary or severe weather keep an active fuel bed averaging ten to twelve inches deep. In milder weather the depth of active fuel may be decreased by keeping a layer of ashes on the grate under the live coals.

Copies of this technical paper may be obtained free of charge by addressing the Director of the Bureau of Mines, Washington, D. C.

Fuel Administration Wants Uniform Regulation

The United States Fuel Administration has advised all state fuel administrators east of the Mississippi River and also those of Minnesota and Louisiana in part as follows:

As a result of various restrictive regulations established locally by state fuel administrators in certain states, we are receiving many complaints of discrimination between different states and inequalities in the requirements of neighboring communities. Fuel Administrator Garfield has concluded that regulations in every state should in general be uniform with those promulgated by Washington. This does not absolutely prohibit additional local regulations where they are necessitated by extraordinary local emergency.

We particularly desire to secure uniform regulations for the whole country at the earliest possible date, not later than Feb. 6.

In general, we feel that the United States Fuel Administrator's order of Jan. 17 is sufficiently drastic and that further extensions should not be attempted unless absolutely required by local emergency and substantially supported by local sanction.

If you have already established additional regulations, we ask that you announce a date in the near future, after which regulations in your state will be uniform with those of Washington.

Dam's Effect on Subsurface Waters

Where a power company by erecting and maintaining a dam across a stream raises the level of the water so that flow of percolating waters from adjacent lands owned by others is obstructed, and where the impounded water of the stream percolates through the adjoining land, causing subsurface waters under such land to rise and remain so near the surface as to injure the land and the crops and improvements thereon, damages may be recovered by the landowner against the power company on the theory of unreasonable interference with his enjoyment of his property. (Florida Supreme Court, Cason vs. Florida Power Co., 76 Southern Reporter, 535.)

It is difficult to put ordinary wood screws into hard timber; the thread in the wood keeps stripping, and the head of the screw may break. It can be easily done, however, in the following way: Grind or file another screw flat on one side to the form of a half-round or shell bit to be used as a tap. A small hole is first bored into the hard timber and the tap screwed into it. It will cut a good thread, and the screw can then be easily turned into the hole if it is well coated with tallow.

New Publications

Central Stations. By Terrell Croft. Published by McGraw-Hill Book Co., New York, 1917. Cloth; 5¼ x 8 in.; 332 pages; 306 illustrations. Price, $2.

Although this book has been written, as its name would indicate, to deal with central-station practice, nevertheless the major portion of the work can be read with profit to himself by almost anyone interested in the generation, transmission and distribution of electric power. The work is divided into eighteen sections. The opening section defines the terms most commonly used to designate the different components of an electrical-energy-distribution system; then the other chapters following in order take up: Distribution loss and distribution-loss factors; maximum demand, maximum-demand meters and demand factors; diversity and diversity factors; load factor, plant factor and connected-load factor; load graphs and their significance; general principles of circuit design; calculation and design of direct-current circuits; calculation and design of alternating-current circuits; transmission and distribution of electrical energy; lightning-protection apparatus; automatic voltage regulators; switchboards and switchgear; characteristics of electric-generating stations; adaptability of steam, internal-combustion engine, and hydraulic prime movers; steam-electrical-energy generating stations; internal-combustion-engine stations, and hydro-electric stations.

The treatment of alternating-current problems usually involve more or less complicated trigonometric expressions; however, the author, in the many problems on alternating-current circuits treated in this book, keeps within the bounds of simple arithmetic, therefore he can be comprehended by the reader of only limited mathematical attainments.

As the dimensions in the book would indicate, its treatment of central-stations practice must needs be limited, and in this case is confined to the practical side of the subject; therefore, the work will meet the needs of the practical electrician and station operator rather than those of the designing engineer, and it should fill a large field of usefulness with the former class of readers.

Personals

Capt. C. W. Dyson, U. S. N., of the Bureau of Steam Engineering of the Navy Department, has been promoted to the rank of rear admiral.

Rear Admiral R. S. Griffin, U. S. N., chief of the Bureau of Steam Engineering, has been reappointed as engineer-in-chief of the navy for another term of four years.

F. E. Pratt, formerly representative of the Worthington Steam Pump Co. in Brazil, is now New York sales manager of the Steam Motors Co., Inc., with offices at 30 Church St.

E. P. Worden, formerly chief engineer of Henry R. Worthington Pump Corp., has resigned to accept the position of mechanical engineer for the Submarine Boat Corp., New York.

J. H. Pardee, president of The J. G. White Management Corporation, New York, and J. P. Ripley, engineer, have returned to New York from a general inspection of the Manila Electric Railroad and Light Co. and other interests in the Philippine Islands operated by The J. G. White Management Corporation.

Engineering Affairs

The American Society of Mechanical Engineers announces the following sections meeting: Buffalo, N. Y., Feb. 26; Meriden, Conn., Feb. 14; New York City, Feb. 21; Philadelphia, Feb. 26.

New York Chapter A. A. E.—At the next meeting of the New York Chapter of the American Association of Engineers, which will be held at the Hotel McAlpin on Wednesday, Feb. 13 at 8 P.M., H. H. Bubar, of the National Aniline and Chemical Co., will speak on "The Engineer; His Present and Future."

The Trustees of the United Engineering Society, held their annual meeting Jan. 24, and elected the following officers for the ensuing year: President, Charles F. Rand, member A. I. M. E.; first vice president, Calvert Townley, member A. I. E. E.; second vice president, Robert M. Dixon, member A. S. M. E.; treasurer, Dr. Joseph Struthers, member A. I. M. E.; secretary, Alfred D. Flinn, member A. S. C. E.; chairman finance committee, J. Vipond Davies, member A. S. C. E.

The American Institute of Electrical Engineers will hold its sixth annual midwinter convention on Feb. 15 and 16, in the Engineering Societies Building, New York City. The convention will include four technical sessions, which will take place on Friday morning, afternoon and evening, and Saturday morning. A strictly informal dinner will be held at the Cafe Boulevard, 41st St. and Broadway, on Friday evening, Feb. 15, at 6:30 o'clock. The session on Friday morning will be devoted to "Circuit-Breaker Ratings." One paper will be presented, "Rating and Selection of Oil Circuit-Breakers," by E. M. Hewlett, J. M. Mahoney and G. A. Burnham. The session on "Meters and Measurements" will be held on Friday afternoon. Four papers are scheduled for this meeting: "A New Standard of Current and Potential," by C. T. Allcutt; "The Thermoelectric Standard Cell," by C. A. Hoxie; "The Character of the Thermal-Storage Demand Meter," by P. M. Lincoln; "Measurement of Power Losses in Dielectrics of Three-Conductor High-Tension Cables," by F. M. Farmer. Dr. A. C. Crehore will lecture at the Friday evening session on "Some Applications of Electromagnetic Theory to Matter." This lecture will be followed by a discussion. The session on "Alternating-Current Commutator Motors" will be held Saturday morning. Three papers will be presented: "Commutation in Alternating-Current Machinery," by Marius A. C. Latour; "The Secomor—a Kinematic Device Which Imitates the Performance of a Series-Wound Commutating Motor," by V. Karapetoff; and "The Polyphase Shunt Motor," by W. C. K. Altes.

Miscellaneous News

A Boiler Exploded at the plant of the Leesburg Silica Sand Co., near Mercer, Penn., Jan. 25, killing two and injuring two men. The cause of the explosion is unknown.

A Boiler Explosion in a shoe store at Peterboro, Ont., on Jan. 26 caused a fire that wiped out one-half of the business section of the town, entailing a loss of half a million dollars damage.

National Labor Policy Board Authorized—Acting on the recommendation of the Advisory Council (on labor problems), the Secretary of Labor will appoint a Policy Board, which will formulate a program for the settlement of difficulties between employers and employees arising during the war. It will be composed of twelve persons. The American Federation of Labor has been asked to nominate five persons to represent the workers and the National Industrial Conference Board five to represent the employers. Each group will nominate a representative of the public, thus completing the board.

New Power House Extension—The steel framing of the extension of the new power house of the Binghamton (N. Y.) Light, Heat and Power Co., is completed and the roof and side walls are well under way, being, on Jan. 19, about 50 per cent. finished. Work has been started on the installation of the additional boilers. The concrete work is in such condition that with a few warm days this end can be finished. During the enforced industrial shutdown it was possible to close this plant completely and to do a considerable amount of construction work to good advantage, with some saving in cost over what it would have been if the work had been done while the plant was running.

A Boiler Exploded on the Weirich farm, west of Washington, Penn., on Jan. 17 and damaged considerable property. Fortunately no one was injured. The cause of the explosion was a most unusual one. A contracting company was putting in a switch from the B. & O. railroad to the coal works, when one of the piles that was being driven for a trestle struck and broke a 5-in. oil line. The oil gushed out, ran down the hill to the boiler and caught fire, and in less than five minutes the boiler let go and was wrecked completely. Two tool sheds standing nearby were also burned. The property loss amounted to about $5000, as well as a financial loss occasioned by the holding up of the work awaiting new equipment.

Flywheel of Stoker Engine Burst — A series of circumstances led up to the injury of one man and the curtailment of the electric service in Cumberland (Md.) and the Georges Creek region early Monday morning, Jan. 21. It appears that some repair parts had been ordered and shipped by express from Boston on Jan. 8 for the governor of the stoker engine in the plant of the Edison Electric Illuminating Co. of Cumberland, but were not delivered as promptly as expected. In the meantime the engine was being operated and, although given unusual attention, it raced and burst the flywheel. Fragments of the wheel struck and broke the arm and hand of one of the employees. The service on several lines of electric railway was reduced one-half and all users of electric current were urged to minimize their demands so that all might have part service.

Drug Stores Recruiting Agents for Merchant Marine—Five hundred and twenty-six druggists scattered all over the New England States, from Fort Kent, Me., to Greenwich, Conn., and from Swanton, Vt., to Nantucket, have volunteered as recruiting agents for the new merchant marine, and will begin their official labors Feb. 4, according to a statement issued by Henry Howard, Director of Recruiting for the United States Shipping Board, Custom House, Boston, Mass. Each of the druggists will conduct an enrolling station at his store, at which young Americans from 17 to 27, inexperienced in seagoing, may put their names to applications for training as sailors firemen, oilers, water-tenders, cooks or stewards, on ships of a training squadron maintained by the Shipping Board, with headquarters at Boston, for preparing crews to serve on the new cargo fleets of the merchant marine. The coöperation of the druggists with the Shipping Board was brought about through the initiative of Louis K. Liggett, of Boston.

Government Control of Fuel Oil—On Feb. 4 President Wilson issued his proclamation putting under license manufacturers and distributors of fuel oil with an output of more than 100,000 barrels a year. The proclamation went into effect Feb. 11.

Preference in shipments is to be given first for war purposes at home and abroad, public utilities and private consumers in the order of necessity.

The classes referred to and the order of their preference are: (1) railroads and bunker fuel; (2) export deliveries or shipments for the United States army or navy; (3) export shipments for the navies and other war purposes of the Allies; (4) hospitals where oil is now being used as fuel; (5) public utilities and domestic consumers now using fuel oil (including gas oil); (6) shipyards engaged in Government work; (7) navy yards; (8) arsenals; (9) plants engaged in manufacture, production and storage of food products; (10) army and navy cantonments where oil is now being used as fuel; (11) industrial consumers engaged in the manufacture of munitions and other articles under Government orders; (12) all other classes.

Mark L. Requa, recently appointed Oil Director by Dr. Harry A. Garfield, Fuel Administrator, will have power to move oil to those industries needing it most, classes of priorities being issued by President Wilson in rules and regulations governing those distributors licensed. The proclamation is essentially a war distribution measure and exerts no control or restriction over the oil wells. Government officials say there is no shortage of fuel oil or gasoline production.

Traffic congestion preventing sufficient shipments to the Allies and allowing the movement of fuel oil to industries that are secondary in importance to war needs, caused the Government to issue the order.

Business Items

The January Issue of the "Walworth Log" is largely devoted to the newly opened Seattle branch of the Walworth Manufacturing Co. We recognize the work of L. F. Hamilton.

Walter A. Zelnicker Supply Co., of St. Louis, has established permanent offices at Minneapolis, Minn., at 627 Plymouth Building, to serve the North Central and Canadian trade. Richard K. Papin, formerly St. Louis and Southwestern representative of the Davenport Locomotive Works and for ten years manager of the Zelnicker Co.'s equipment department, is in charge. He is especially qualified to handle inquiries on rails, locomotives, cars, machinery, piling, tanks, etc., in his district.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 7, 1918	One Year Ago	Feb. 7, 1918	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Feb. 7, 1918	One Year Ago	Feb. 7, 1918	One Year Ago
Clearfields....	....	$3.00	....	$4.25—5.00
Cambrias and Somersets...	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 7, 1918	One Year Ago	Feb. 7, 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$6.50—6.75
Buckwheat ..	4.30—5.00	2.75	5.50—6.00	6.00—6.25
Rice	3.75—3.95	2.20	4.50—5.00	4.50—5.00
Barley	3.25—3.50	1.95	4.00—4.25	3.25—3.75
Boiler	3.50—3.75	2.20	....	....

Bituminous smithing coal, $4.50—5.25 f.o.b.

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)................	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higber than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide		Independent
	Feb. 7, 1918	One Year Ago	Feb. 7, 1918		One Year Ago
Buckwheat ..	$3.15-3.75	$2.50	$3.75	$3.40	$4.15
Rice	2.65-3.65	2.10	3.65	3.00	3.35
Boiler	2.45-2.85	1.95	3.55	3.15	....
Barley	2.15-2.40	1.85	2.40	2.05	2.35
Pea	3.75	2.80	4.65	3.70	....
Culm	....	....	....	....	1.25

No. 5 washed	2.15-2.30	3.00	2.15-2.30	2.75-3.00	2.15-2.30	2.50

Williamson-Franklin rate St. Louis, 87½c.; other rates, 72½c.

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump and Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona....	2.15	2.40	1.90
Black Creek, Cahaba ...	2.40	2.65	2.15

Government figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

PROPOSED CONSTRUCTION

Ala., Alexander—City plans to issue $10,000 bonds for the erection of an addition to its electric-lighting plant. J. A. Coley, Ch. Engr.

Ala., Mobile—The Mobile & Ohio Ry. plans to install electrical equipment in its grain elevator which is nearing completion. P. A. Wood, Ch. Engr.

Ark., Osceola—Town plans to install a 200 kva. generating unit in its electric-lighting plant. E. Teaford, Mgr.

Calif., Palo Alto—City voted $66,000 bonds to install a Diesel engine in its electric-lighting plant. J. F. Byxbee, Jr., City Engr. Noted Jan. 8.

Fla., Pensacola—The Pensacola Electric Co. plans to build a 13,200 volt transmission line from here to Pensacola Naval Station. T. J. Hanlon, Jr., Mgr.

Ga., Portland—The American Potash Co. is in the market for 200 kw. electrical equipment to operate fuller mills for manufacturing potash from sericite.

Kan., Leon—City having preliminary plans prepared by W. B. Rollins & Co., Engr., 209 Ry. Exch. Bldg., Kansas City, Mo., for the erection of an electric-lighting plant.

Ky., Walton—The Walton Electric Light Co. is in the market for an electric generator.

Mich., Marquette—City is having preliminary plans prepared for the erection of a power plant to include a 140 ft. pentstock. Estimated cost, $150,000. M. H. Wright, City Engr.

Miss., Canton—City plans to install new equipment in its electric-lighting plant including a surface condenser for a 200 hp. engine and spray equipment for cooling. J. T. Sharp, Jr., Mgr.

Miss., Houston—City plans to install new equipment in its electric-lighting plant including an 80 hp. crude oil engine directly connected to a 60 kw., 3 phase, 2300 volt, revolving field motor and switchboard, etc. A. G. Atkinson, Supt.

Mo., Wellsville—The Blattant Poultry and Manufacturing Co. plans to rebuild its electric-lighting plant which was recently destroyed by fire.

Neb., Falls City—City voted $75,000 bonds for the erection of an electric-lighting plant. K. J C. Mullen, City Clerk. Noted Dec. 25.

Neb., Juniata—City plans an election soon to vote on a $7000 bond issue for the erection of a transmission line from here to Hastings.

N. J., Jersey City—The Board of Freeholders, Hudson County, is having plans prepared by P. A. Vivarttas, Arch., 110 4th St., West New York, for the erection of a 1 story, brick, power house and electric lighting plant. Noted Dec. 18.

N. Y., Albion—The State is in the market for two 150 hp. horizontal tubular boilers. Estimated cost, $10,000. L. F. Pilcher, Capitol, Albany, Arch.

Okla., Canadian—City plans to vote on bond issue for the erection of an electric-lighting plant.

Penn., Harrisburg—The Harrisburg Light and Power Co. plans to improve and enlarge its plant; also install 4 new stokers.

Penn., New Castle—The Mahoning & Shenango Ry. and Light Co. has been granted permission by the Public Service Commission to issue $2,000,000 bonds; the proceeds will be used to build additions and improvements to its system. E. H. Bell, Youngstown, Ohio, Mgr.

Va., Richmond—The Virginia Ry. and Power Co. plans to erect a 21 x 116 ft. concrete addition to its power house on 12th St. C. B. Buchanan, Gen. Mgr.

Wash., Seattle—The Board of Public Works will receive bids until March 1 for the erection of an addition to its hydro-electric power plant. Estimated cost, $5,000,000. J. D. Ross, Supt. of Light and Power.

Wash., Tacoma—City having plans prepared for the erection of an additional power plant with 17,000 hp. capacity. Estimated cost, $1,000,000. L. Evans, Gen. Supt.

Wis., Madison—The Di-Electric Manufacturing Co., incorporated with $40,000 capital stock, plans to build a plant. E. W. Smythe, Jr., Vroman Blk., and E. K. Frautschi, incorporators.

B. C., Nelson—The Swanetta Power Co., incorporated with $500,000 capital stock, plans to build a large hydro-electric plant on the Bend d'Oreille River, south of Nelson.

Ont., Elmira—A. S. Gingrich is in the market for a 30 to 35 hp. oil engine.

Ont., Hamilton—The Wentworth Orchard Co., Sun Life Bldg., is in the market for a 5 hp. electric motor for hydro power.

Ont., Merritton—The Riordon Pulp and Paper Co., Ltd., 355 Beaver Hall Sq., Montreal, will soon award the contract for the erection of a power plant.

Ont., Renfrew—The British Explosives, Ltd., is in the market for several $^{1}/_{15}$ hp. and ½ hp. electric motors. W. C. Cram, Mgr.

Ont., Toronto—E. Pullen, 20 Main St., is in the market for a 10 hp. D. C., 550 volt, high speed motor.

The Secret

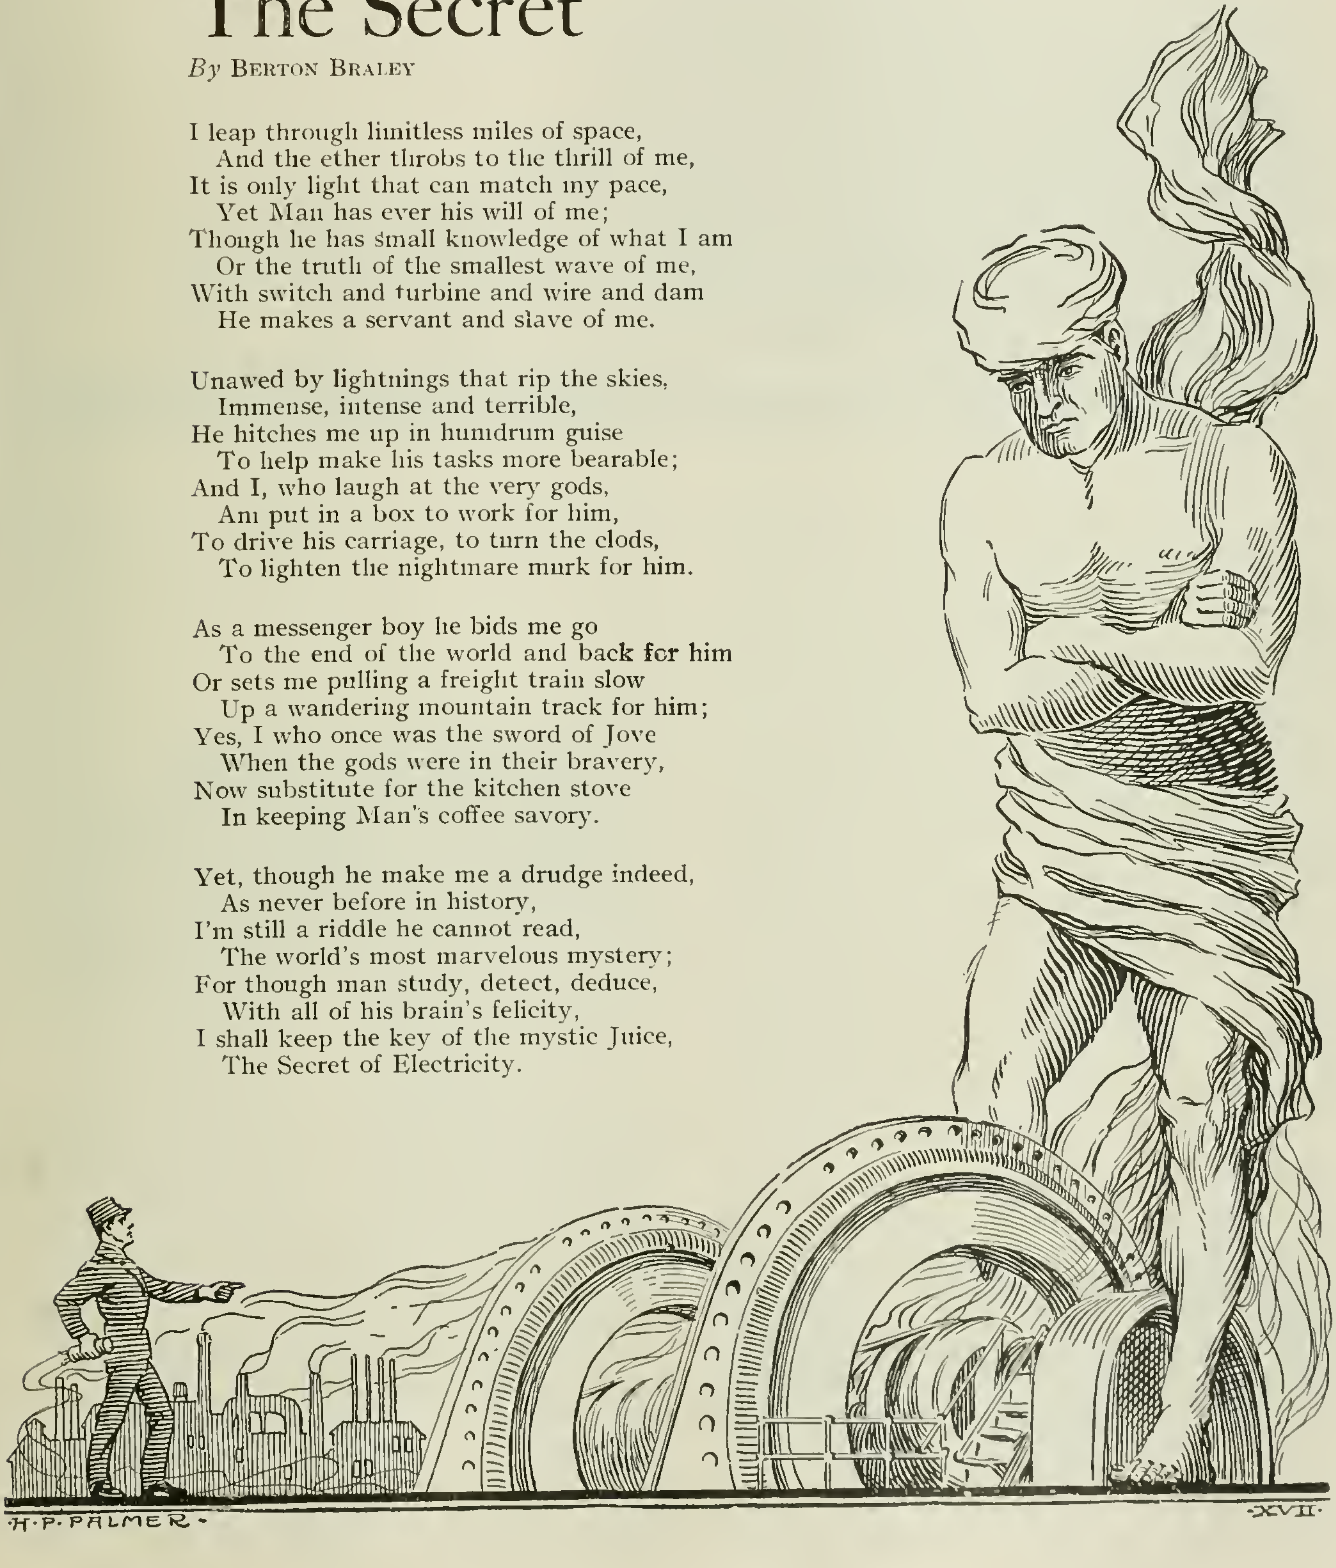
By Berton Braley

I leap through limitless miles of space,
  And the ether throbs to the thrill of me,
It is only light that can match my pace,
  Yet Man has ever his will of me;
Though he has small knowledge of what I am
  Or the truth of the smallest wave of me,
With switch and turbine and wire and dam
  He makes a servant and slave of me.

Unawed by lightnings that rip the skies,
  Immense, intense and terrible,
He hitches me up in humdrum guise
  To help make his tasks more bearable;
And I, who laugh at the very gods,
  Am put in a box to work for him,
To drive his carriage, to turn the clods,
  To lighten the nightmare murk for him.

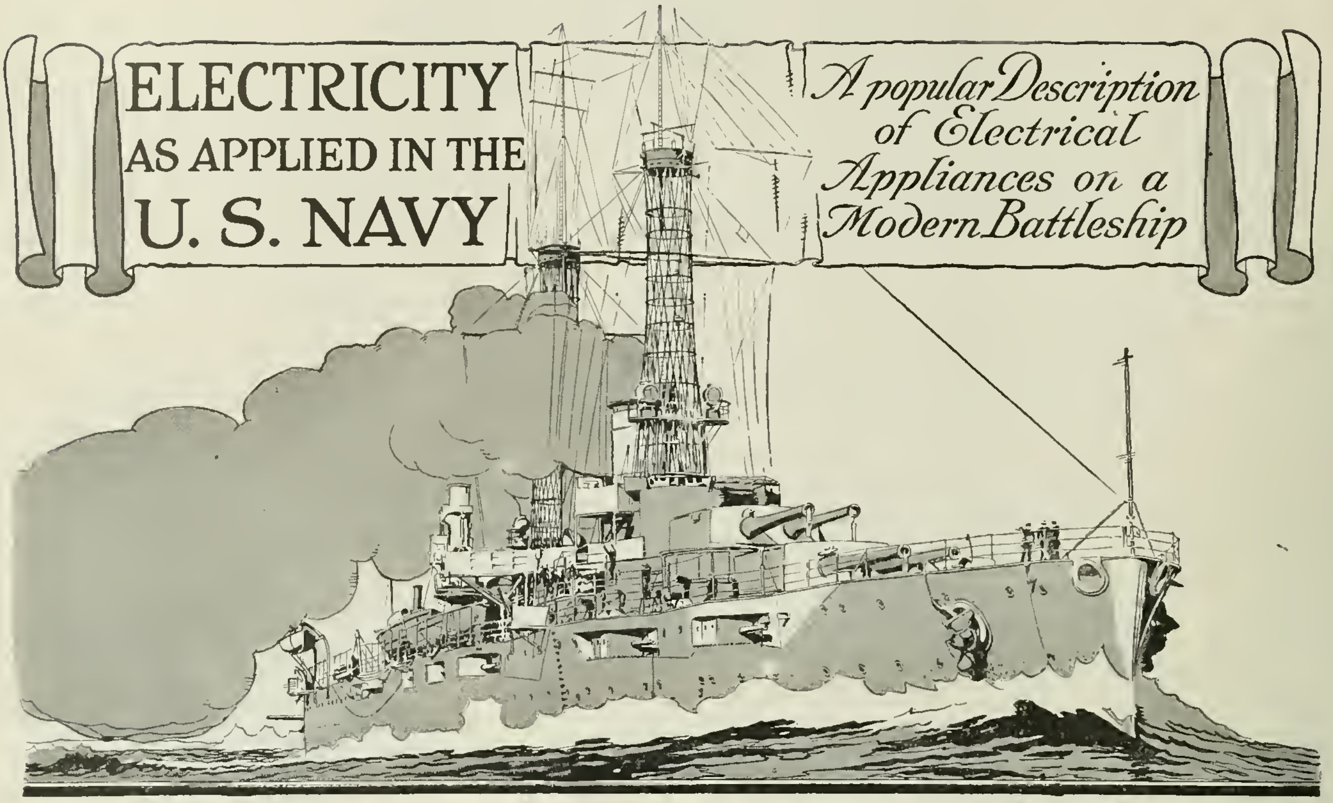
As a messenger boy he bids me go
  To the end of the world and back for him
Or sets me pulling a freight train slow
  Up a wandering mountain track for him;
Yes, I who once was the sword of Jove
  When the gods were in their bravery,
Now substitute for the kitchen stove
  In keeping Man's coffee savory.

Yet, though he make me a drudge indeed,
  As never before in history,
I'm still a riddle he cannot read,
  The world's most marvelous mystery;
For though man study, detect, deduce,
  With all of his brain's felicity,
I shall keep the key of the mystic Juice,
  The Secret of Electricity.



ELECTRICITY AS APPLIED IN THE U. S. NAVY

A popular Description of Electrical Appliances on a Modern Battleship



UNTIL recent years the application of electricity to the operation of the various devices on board ship has been slow. This has been true of marine work in general. The most conspicuous exception to this rule has been in the American Navy, which is not only a larger user of electrically driven machinery than the merchant marine, but also leads the navies of the world in the application of electricity to the almost countless devices used on board a modern battleship.

The employment of electricity on shipboard was at first limited to illuminating purposes and searchlights. On the cruiser "Brooklyn," which was launched in 1895, electric motors were used to drive the ammunition hoists and for turning two of the turrets, but it was not until the launching of the battleships "Kearsarge" and "Kentucky" in 1898 that an extensive use of electrically driven auxiliaries began. Since then the use of electricity has been extended until today some of our largest and most powerful superdreadnaughts and battle cruisers are electrically driven. As an illustration of this, the superdreadnaught U.S.S. "Tennessee," which has a displacement of 32,600 tons and is designed for a speed of 21 knots per hour, will be driven by four alternating-current motors, one on each propeller. Each motor will have a normal capacity of 6700 hp. and a 25 per cent. overload rating, or 8375 hp. for four hours. Power will be supplied by two 13,500-hp., standard steam turbo-alternators similar to those used in large power houses throughout the country (Fig. 1). In addition to the main generators there will be six 300-kw. direct-current geared-turbine-driven auxiliary units, similar to that shown in Fig. 2, to furnish current for exciting the alternators and for light, power, signals and several hundred motors used about the ship. This equipment was described in *Power*, Aug. 7, 1917 issue.

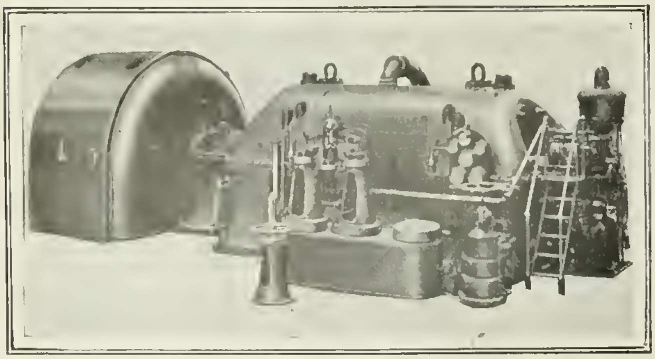


FIG. 1. STANDARD STEAM TURBO-ALTERNATOR

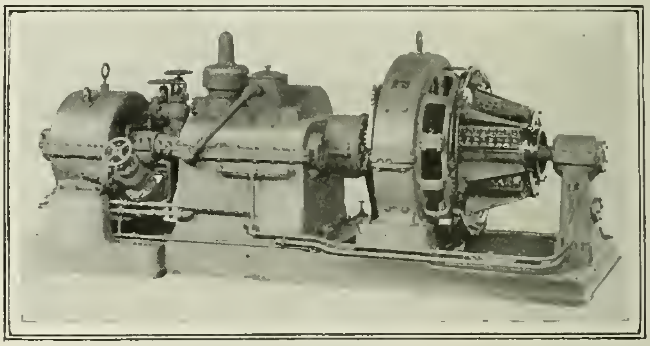

FIG. 2. GEARED-TURBINE, DIRECT-CURRENT GENERATOR

The first ship of any importance, excepting submarine boats of the navy, to be electrically driven was the U. S. collier "Jupiter," which was built at the Mare Island Navy Yard and put in commission Sept. 15, 1913. This vessel is of about 20,000 tons displacement and is designed to carry 12,000 tons of coal or oil. The main units of this boat consist of one alternating-current turbo-generator set of 7000 hp. and two 3500-hp. wound-rotor induction motors, wound for 3400 volts. The stator and rotor of one of the motors are shown in Figs. 3 and 4 respectively.

The electrical installation on board a modern battleship may be divided into three general systems—power, lighting and signaling. Outside of the main drive, when the vessel is electrically driven, the power plant usually consists of a number of 300- to 375-kw. turbine-driven 125- or 250-volt direct-current generators, although in some of the oldest ships 80-volt equipments are used. As pointed out in a previous paragraph, the superdreadnaught "Tennessee" will have six 300-kw. direct-current units in the auxiliary power plant. The generators of the earlier equipment were direct-connected to the turbine, ran at a speed of 1500 r.p.m. and were of the compound-wound type with commutating poles. In the more modern equipments geared turbines are used and the generator operates at from 700 to 1000 r.p.m. On account of the comparatively heavy current and small diameter of the commutator, the 125-volt units generally have two commutators, one at each end of the armature.

It is general practice to provide not less than four of these sets and locate them in two separate dynamo rooms, so that in case of the disablement of one dynamo room the entire electrical equipment will not be put out of business.

The method of operating the generators varies somewhat with different nations. In America it is general practice to operate them in parallel, while in Europe in many cases the generators are arranged so that the distributing circuits can be transferred from one generator to another, but the generators cannot be operated in parallel.

Figs. 5 and 6 show the back and front view of a switchboard used for the control of the direct-current power plant on a modern battleship. On the center panels are mounted the switches, circuit-breakers, instruments, etc., for the control of two generator sets, either or both of which may be connected to the busbars. The end panels are for the control of the distributing circuits. Circuit-breakers are used to protect the large-capacity circuits, while fuses are used on the smaller circuits. Where the power plant is divided and located in different rooms, tie lines are provided between the different switchboards so that the machines in one generator room may supply power to busbars of the switchboard located in the other room. In addition to the main switchboard other distributing panels are located in the various parts of the ship for the control of motors and distribute the current to the various equipments.

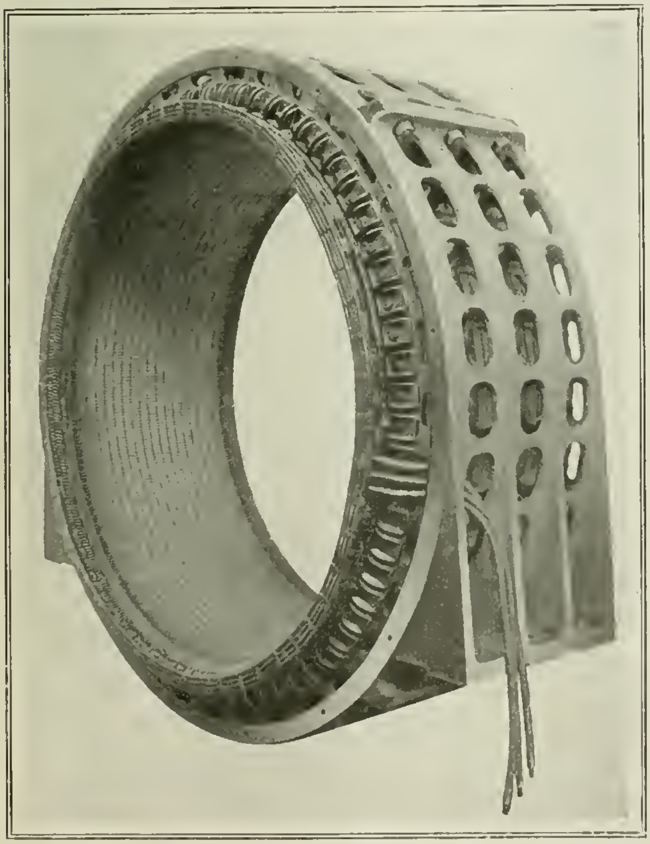

FIG. 3. STATOR OF ONE OF THE JUPITER'S MOTORS

FIG. 4. ROTOR OF THE STATOR, FIG. 3

In America the earlier practice was to construct the switchboard panels of slate mounted on angle-iron supports, and sometimes cushioned with rubber to prevent breakage. The more modern practice is to construct the panels of nonfragile insulating material, such as asbestos lumber. In Europe the panels are frequently made of steel with the instruments insulated therefrom.

The largest and one of the most important applications of electricity on board ship is the steering gear. The operation of the steering gear by some power means dates back to the "Great Eastern," on which was placed a steam-operated steering equipment. The success of this installation soon led to the general adoption of steam-operated steering gears on most all classes of vessels. Although electrical steering gears have been given attention for some twenty or twenty-five years past, it is only within recent years that they have been adopted in general. At first they were applied in conjunction with steam engines, the electrical drive acting as an auxiliary.

One of the first systems to be successfully employed, utilized a motor-generator set to supply power to a shunt motor for operating the rudder. Control with this system was effected on the Wheatstone-bridge principle and is known as the "Pfatischer" system, one arm of the rheostat being located at and operated from the steering stand and the other located at and operated by the rudder.

This system followed along the idea of the old follow-up system, used with the steam engine; that is, the helmsman sets the steering wheel at the angle it was desired to have the rudder moved to, and when the latter arrived at this position it automatically cut out the source of driving power.

Quite a number of the United States battleships and cruisers are equipped with a rheostatic system of control on the steering gear. The motor is fed directly from the ship's mains, thus obviating the use of a motor-generator set. With the rheostatic control the motor is controlled by the use of a contactor panel, Fig. 7, equipped with contactors for reversing the motor, cutting out the armature resistance, for operating at slow speeds and for dynamic braking. The controller, along with the starting resistance, is usually placed near the motor and operated from a steering stand, Fig. 8, located at steering stations in different parts of the ship. The helmsman can always tell the position of the rudder by a helm-angle indicator located near the steering stand. To prevent the rudder from jamming on the hard-over position, limit switches are provided similar to the one shown in Fig. 9.

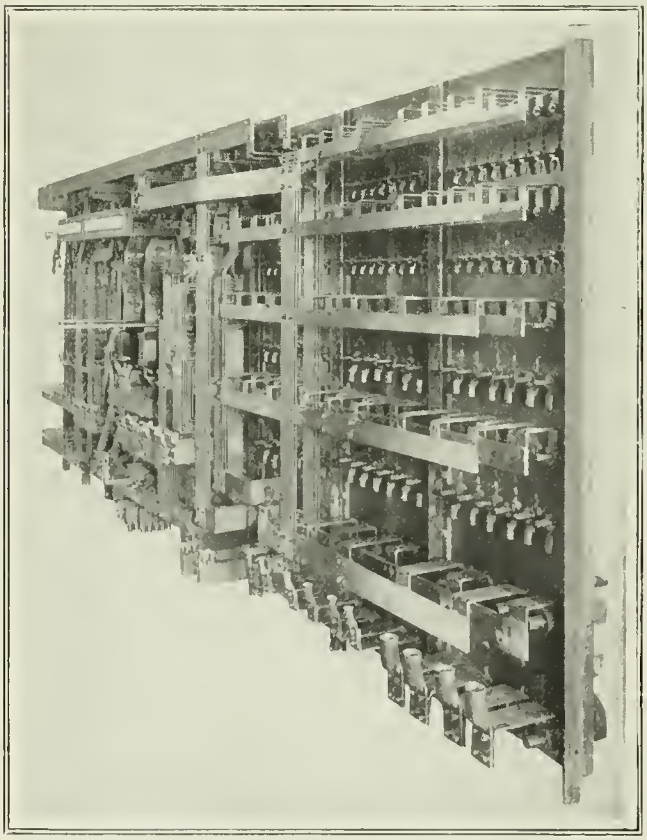

FIG. 5. BACK VIEW DIRECT-CURRENT SWITCHBOARD

The system which is now receiving favorable consideration at the hands of the Navy Department involves the use of a hydraulic mechanism to operate the rudder. A variable-stroke hydraulic pump delivers oil to large rams connected to the rudder crosshead, and this variable-stroke pump is driven by a constant-speed motor, which is started up and allowed to run continuously. A small pilot motor operates the valve of the hydraulic variable-stroke pump, and the control of this pilot motor, from various stations in the ship, is the same as the rheostatic system described in the foregoing.

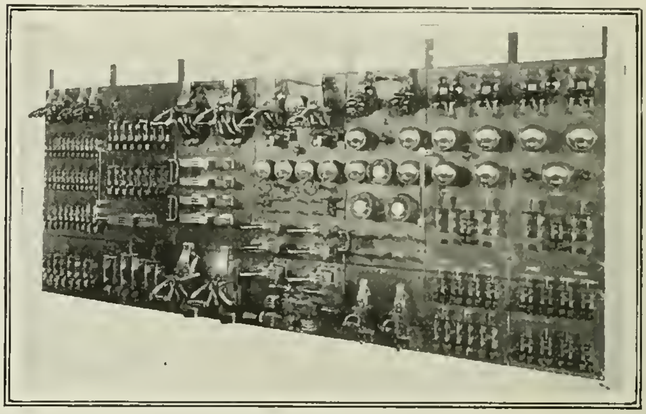

FIG. 6. FRONT VIEW DIRECT-CURRENT SWITCHBOARD

While this hydraulic-electric steering-gear system may be said to be still somewhat in the experimental stage, it is being installed at the present time quite generally on large naval vessels. Its principal point of advantage is that it substitutes the hydraulic variable-stroke pump and hydraulic ram for the very inefficient screw-gear arrangement previously used on all the old vessels, and therefore permits the installation of a motor of relatively small horsepower for driving the rudder.

The requirement on nearly all naval vessels is that the motor must operate the rudder from hard-over to hard-over in twenty seconds. On the most recent and largest vessels, it has been modified in some cases to thirty seconds. With the rheostatic control on the larger battleships, compound-wound interpole motors of 300-hp. capacity are required to operate the steering gear, while with the hydraulic-electric the horsepower is reduced to about one-half, or 150. Fig. 10 shows a pair of 175-hp. steering-gear motors operating in parallel on a single rudder shaft. The motors are equipped with disk brakes on the armature shaft, which, assisted by dynamic braking, brings the rudder to rest.

Another service that requires large motors on board ship is the anchor windlass. On some of the recent equipment installed on American battleships, two motors are used, each having a one-hour rating of from 125 to 150 hp. The motors are compound-wound and equipped with commutating poles and a disk brake, and are coupled directly to the two worm gears through which the windlass is operated. The control of the motors is such that each can be operated independently as well as the two simultaneously in series or parallel. The equipment is capable of raising two 20,000-lb. anchors simultaneously and 360 ft. of chain on each, each chain weighing about 36,000 lb., at the rate of 36 ft. per minute.

The cranes for handling the lifeboats are operated by compound-wound motors, usually of 50-hp. capacity, one of which is shown in Fig. 11. In this equipment the requirements are that it raise a 40,000-lb. load at

20 ft. per min. and the empty hooks at 60 ft. per min. The motor is equipped with an electric brake so that it will hold the load if the power fails. A motor is also used for rotating the crane so as to place the boats in position on deck. The capacity of this motor is frequently 50 hp. A rheostatic controller for a boat-crane motor is shown in Fig. 12.

Winch motors for both coal and cargo are 35 to 45 hp. in size, compound-wound and equipped with interpoles. The winches for coal handling are generally capable of handling a 5000-lb. load at 200 ft. per min. and a 20,000-lb. load at 50 ft. per minute.

Forced ventilation is an important feature in the operation of a modern battleship. On large ships the ventilation system may consist of over one hundred electrically driven fans, handling 500,000 cu.ft. of air per minute. The size of the motors varies from 1 to 15 hp. In addition to the ventilation motors, there may be as many as 200 small desk or bracket fans in use. In the latest practice on battleships steam turbines are being used extensively for driving the ventilating fans.

Electrically driven pumps are used for various purposes, such as fire, fresh-water supply, bilge, drainage tanks, sanitary purposes, refrigeration, etc. These motors vary in size from 1 to 75 hp. To handle the bilge water 15 to 20 pumps are supplied. These pumps require vertical and horizontal motors varying in size from 25 to 75 horsepower.

Motors are used for turning the turrets, elevating the large guns and hoisting ammunition. These services require motors ranging in size from 3 to 35 hp. Variable-speed as well as constant-speed motors are used on the ammunition hoists.

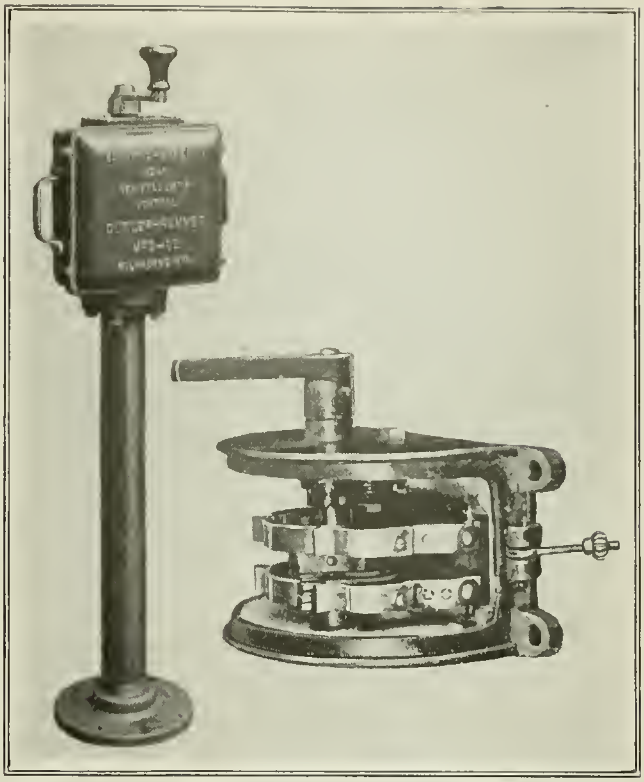

FIGS. 8 AND 9. STEERING STAND AND LIMIT SWITCH

Fig. 8—On left, electric steering stand for non-follow-up system. Fig. 9—On right, rudder limit switch

Electricity is used for almost every imaginable purpose on board the modern battleship. The completeness of the equipment is evident from such items as moving-picture machines, motor-driven cake mixers, ice-cream freezers, etc., which would indicate that about all the luxuries that may be had on land are also provided on board ship.

The illuminating equipment of a battleship consists of from 3000 to 4000 lights. Incandescent lamps are used almost exclusively for this purpose. The fixtures are of special design to make them water-tight and also on account of the vibration of the ship.

The cables must also be of special design on account of the moisture. They are insulated with a high-grade rubber and a suitable braid, and then protected with a lead sheath, covered with metal armor. This cable is quite flexible and can be easily made to conform to almost any contour. The electrical installation on a battleship requires from 75 to 100 miles of cable.

The signaling systems are also a very extensive part of the electrical equipment, consisting of some 40 different systems, including ammunition-hoist indicators, gun firing, turret telephone, fire-control telegraph, engine-room telegraph, fire alarms, torpedo firing, wireless telegraph, etc. A number of these equipments are installed in duplicate and are supplied with power from two sources. The systems operate on voltages ranging from the potential of the power circuit down to 15 volts used for call bells. Both alternating and direct current are used. Alternating current and low-voltage direct current are obtained from motor-generator sets.

One of the most interesting pieces of electrical apparatus on a battleship is the gyroscopic compass. This has completely displaced the magnetic compass on the larger vessels and submarines of practically every navy in the world. The sensitive element is a rapidly revolving wheel which, owing to the peculiar effect of gyroscopic force, keeps its axis parallel to the axis of the earth and hence points to the north pole.

A magnetic compass must be corrected for the iron masses surrounding it and also for the difference between the location of the magnetic north pole and the geographic north pole. As the gyro compass is independent of magnetism, these corrections do not have to be made and calculations based on compass bearings are greatly simplified. The only corrections are for the speed of the ship and for latitude. These corrections are made semi-automatically and involve no calculations.

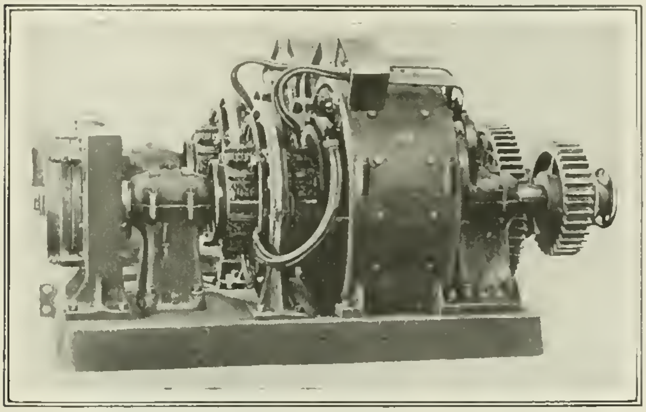

FIG. 10. PAIR OF 175-HP. STEERING-GEAR MOTORS

The complete battleship equipment consists of two master compasses, one of which is shown at *M*, Fig. 13, a number of repeater compasses *R*, a motor-generator set *G*, and a control panel *C* for running either master compass and for interconnecting the repeater compasses in any desired combination.

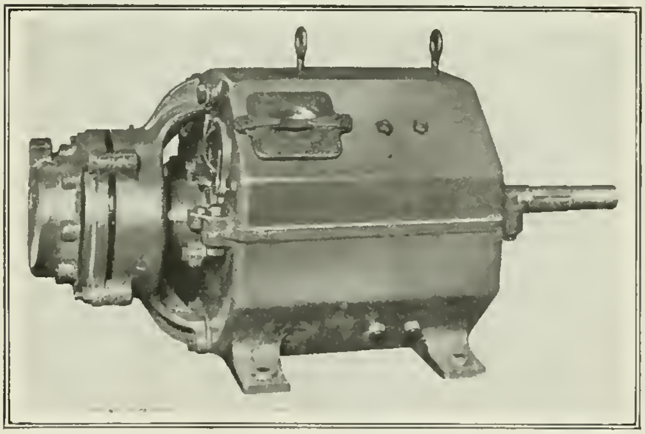

FIG. 11. BOAT-CRANE MOTOR

The repeater compasses contain small motors which are driven by a transmitter in the master compass. The master compass is mounted below deck out of all danger, while the repeater compasses are used in navigating the ship. These repeaters are mounted in different ways—on a stand similar to the ordinary magnetic compass; on the wall; on a pelorus *P*, Fig. 13, for taking azimuth sights directly; and they even may be portable so that the navigating officer may walk around and still have the compass with him.

To the layman the master compass appears to be a tremendously complicated and delicate mechanism. A detailed view of it is given in Fig. 14. Its "sensitive element" is a steel wheel *W*, with its axis horizontal, driven at 8600 r.p.m. by a self-contained three-phase alternating-current motor. This wheel runs in a vacuum to eliminate the air friction, which is very great at the high speed at which it runs. The wheel and case *W* are suspended on a steel cable, which is held at its upper end in a ball bearing. This bearing is covered by a cap which can be seen at *C* in the figure. Connected to this case through the "floating ballistic" is the compass card *D*, Fig. 15, from which the heading is read. The card is kept continually oscillating about half a degree by a small motor, to keep out any slight friction lag in the reading. The force of the gyro does not turn the card directly, but closes contacts at *T* and *T*, which causes a little motor to drive it one way or the other. The transmitting mechanism which controls the repeaters is also operated by this motor. At *W* are shown the small wheels for correcting the

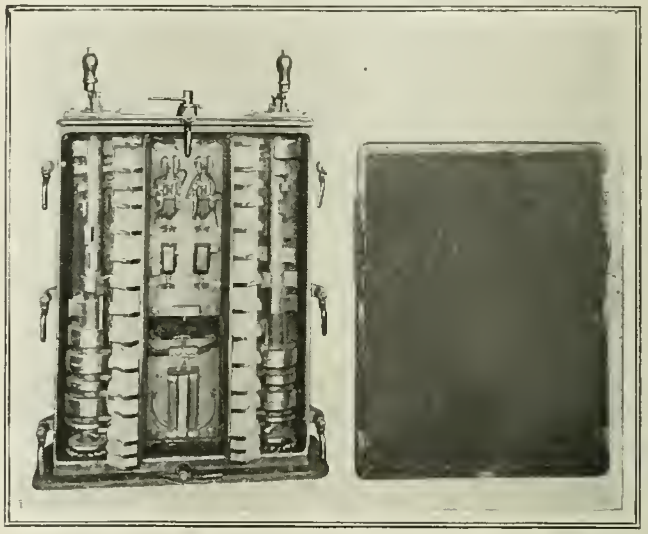

FIG. 12. BOAT-CRANE MOTOR CONTROLLER

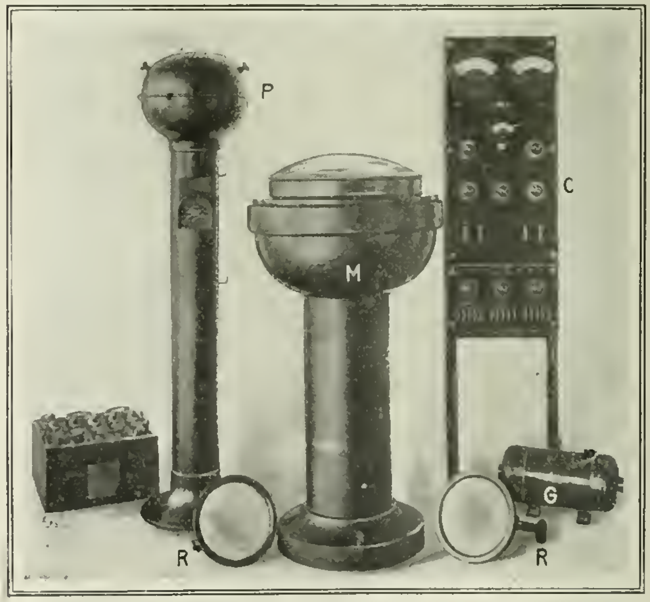

FIG. 13. GYROSCOPIC-COMPASS EQUIPMENT

compass for speed and position. These two knobs operate interconnected cams and link which automatically solve an involved trigonometric equation and make the necessary corrections.

Another interesting and important device used on warships is the high-intensity searchlight, Fig. 16. The beam from this light is the most brilliant known, being equal to the sun's intensity at 8 a.m. or 4 p.m. New York latitude. The size used on ships is 36 in. diameter and will throw a beam 40 miles.

The positive and negative electrodes are respectively 16 and 11 millimeters in diameter in this lamp. Its candlepower is 320,000 per sq.in., and in the 36-in. type it has a beam intensity of 256,000,000 cp. The temperature of the arc is about 5000 deg. C., or 9000 deg. F. The arc running at a temperature of 7000 deg. F. higher than the melting point of the carbon holders is only about one inch away from them. The positive carbon is rotated as it is fed forward, while the negative feeds forward and upward at an angle to meet the positive. The voltage of the arc is approximately 75. When focused sharply, the beam will ignite paper at a distance of approximately 250 ft. A larger size, 60 in. in diameter, used in coast-defense work, is the most powerful light in the world, having a beam of 1,280,000,000 cp. This lamp stands ten feet high and weighs three tons; newspapers may be read in its light thirty miles away. It has been reported that signals flashed by this searchlight were seen 150 miles away. The brilliant light is obtained by the use of special carbons having a deep but small crater in the positive carbon, in which the vapor burns. This gives a beam 3.5 times greater than an arc using ordinary carbons.

FIG. 14. SIDE VIEW OF MASTER GYRO COMPASS

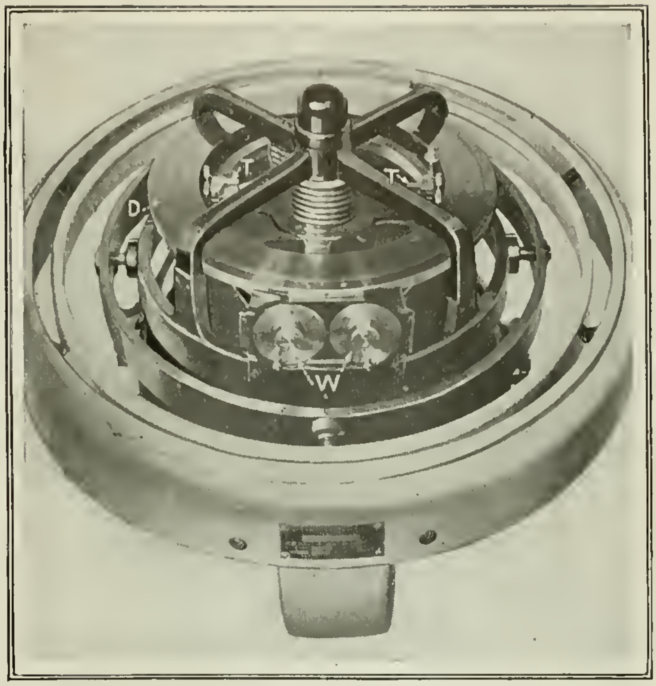

FIG. 15. TOP VIEW OF MASTER GYRO COMPASS

The lamp may be controlled directly by using the handwheel *W*, or it may be trained and elevated by using the remote-control lever *L*, which may be located in any part of the ship. This is a very important feature, as it is much easier to see what the light is disclosing from a point 200 ft. away from the light than from a position near the light itself. It is possible to elevate the lamp to a vertical position, making it available for anti-aircraft work. The shutter, which completely cuts off the beam, may be seen at *S*. The

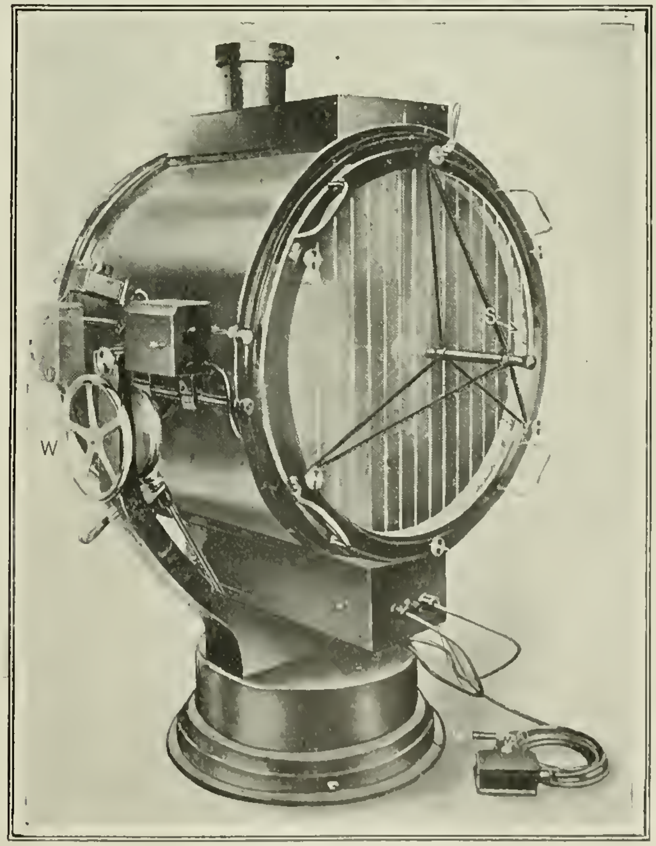

FIG. 16. THIRTY-SIX INCH SEARCHLIGHT

movement of a lever closes it tightly. This feature is very important, as a dying arc makes an excellent target. For this reason the shutter is closed previous to putting out the light, leaving the boat in complete darkness.

The arm of the Navy that is attracting more attention than any other at the present time is the submarine boat. Modern submarine boats are propelled by oil engines on the surface and electric motors when submerged, each propeller shaft being operated by an oil engine or motor according to the conditions of operation, the oil engines operating the motors as generators while on the surface and charging storage batteries, which in the submerged condition, supply current to the motors to drive the boats.

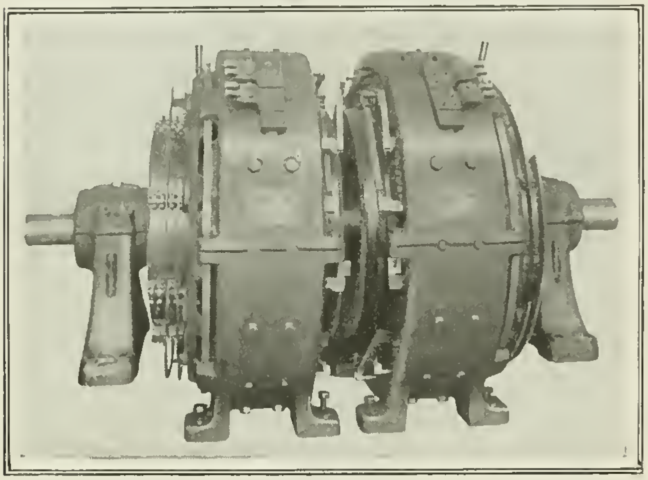

FIG. 17. PAIR OF SUBMARINE PROPELLED MOTORS

The main motors, Fig. 17, one on each propeller shaft, are of large size, varying from 500 to 800 hp. according to the size of the boats, and these motors are remotely controlled by automatic-contactor controllers from a central station. Each motor may consist of two units as in the figure or a single unit according to conditions.

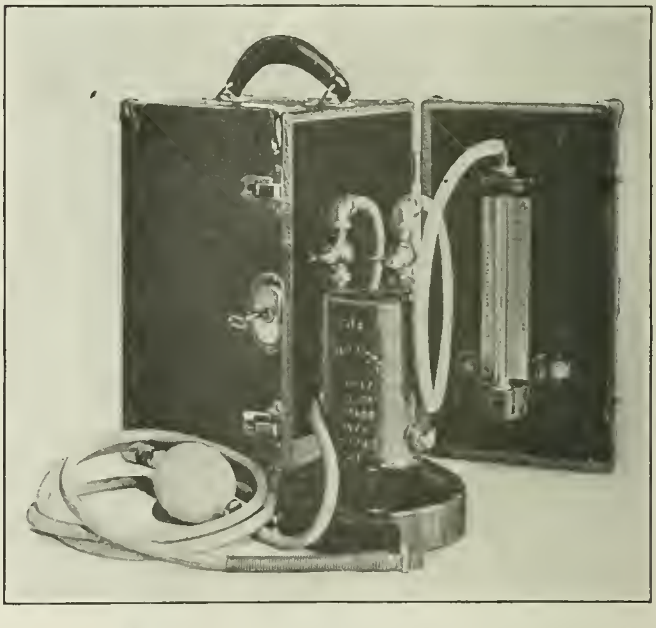
In addition to the main-motor equipments, each submarine is provided with a large number of auxiliary-motor equipments for operating pumps, air compressors, steering gears, diving gears, periscope-lifting gears, etc. The horsepower of these auxiliary equipments varies from about 0.5 to 50 or 60 hp., and the majority of them are operated by contactor push-button controllers. In addition, the submarines are equipped with electric cooking and heating devices and complete sets of wireless and other signaling apparatus.

[Considerable of the material in this article was compiled from articles in the *General Electric Review:* February, 1914, "Electric Propulsion of the U.S.S. 'Jupiter,'" by W. L. R. Emmett; and June, 1915, "Electricity in Marine Work," by Maxwell W. Day. "Electricity the Future Power for Steering Vessels," by H. L. Hibbard, Transactions of the A. I. E. E., Vol. XXXIII, was also drawn upon. This material has been added to when necessary to bring it up to date. The descriptive literature of the Sperry Gyroscope Co. was also consulted. Photographs were supplied by the Westinghouse Electric and Manufacturing Co., the General Electric Co., Cutler-Hammer Manufacturing Co. and the Sperry Gyroscope Co.—Editor.]

Mercury Column Indicates CO_2

The Dwight Manufacturing Co., of Chicago, has added to its line a second form of CO_2 indicator. The use of a mercury column calibrated to indicate directly the percentage of CO_2 is the distinguishing feature. The initial design, which is still retained, used a small spring-type gage for this purpose. Both types are accurate and so rapid in operation as to encourage the consistent use necessary to produce a material saving in coal.

The new instrument, known as type B, is shown in the illustration. It consists of the usual metal reservoir, a specially calibrated mercury gage and the carrying case for the complete outfit. When in service the reservoir is disconnected from the gage and a sample of flue gas pumped through the chamber. A comparatively large supply of potash solution fills the base, and on the surface of this solution floats a layer of mineral oil sealing from the chemical the gas sample being collected. When the gas sample has been obtained, both valves on top of the instrument are closed and the reservoir is shaken back and forth a few times to break the oil seal and allow the chemical solution to absorb the CO_2 from the gas sample. This "splash system" of mixing the gas and liquid produces rapid absorption of the CO_2 on account of the large surface area of fresh chemical brought in contact with the gas. Connection is then made with the mercury gage, as shown in the illustration, and upon opening the communicating valve the percentage of CO_2 in the gas is indicated on the gage.



MERCURY COLUMN CO_2 INDICATOR

In the design proper precautions were taken to trap the mercury so that it cannot spill even when the apparatus is inverted. The graduated scale is movable so that the zero point can be easily set opposite the mercury level when the gage is under atmospheric pressure.

The Canadian Commission of Conservation estimates the total possible water-power resources of the Dominion at 18,803,000 hp., while the developed water power is 1,813,210 hp.—*Commerce Reports.*

The Fifty-Thousand Kilovolt-Ampere Connors Creek Turbines

BY C. F. HIRSHFELD*

Largest single-cylinder turbine. The first of two units now being installed, each to be served by four 2365-hp. boilers. With 70,000 sq.ft. of surface the condenser is the largest yet attempted in a single shell. It has but one water pass, and drain plates spill the condensate into the steam belt, so that its temperature at the hotwell will approximate that corresponding to the vacuum.

THE Connors Creek plant of the Detroit Edison Co. was planned to contain six 25,000-kv.-a. 60-cycle machines supplied with steam from twelve 2365-hp. boilers operating at 225 lb. gage pressure and 200 deg. superheat at 200 per cent. of rating. The first unit was started Feb. 8, 1915; the second July 7, 1915, and the third Feb. 15, 1917. When the fourth unit came up for consideration, it became evident that the development of large turbine units and likewise the growth of the company's load had progressed to such a point that it would be desirable to choose a unit of greater capacity than originally planned. It was then decided to complete the plant by installing two 50,000-kv.-a. machines instead of the three 25,000-kv.-a. units originally contemplated. One of these larger units is now being placed.

EACH TURBINE SUPPLIED BY FOUR BOILERS

Each of these machines will be supplied with steam from four boilers[1] similar to those originally planned, so that the ratio of boiler capacity will not be altered. However, the change involves the ultimate installation of eight boilers instead of the six which would have been required to serve three 25,000-kv.-a. machines. The ultimate capacity of the station as now planned will be 175,000 kv.-a. instead of 150,000 as originally intended.

The turbine for the large unit is of the disk type and represents a development of the design used in the first machines installed in the station. It has 21 stages as against nine in the smaller machines. However, in spite of this fact and also in spite of its larger capacity, the new unit is only fifteen feet longer, over-all, than are the smaller machines. Other dimensions are also much smaller than one would expect from a direct comparison of capacities. The weight is only about 40 per cent. greater than that of the earlier models. The speed, 1200 r.p.m., is the same.

The small physical size in comparison with the earlier units is partly due to refinements in the design of the turbine which have made it possible to greatly decrease the distance between wheels. It is also due in a small degree to higher generating voltage, 12,200 instead of 4600.

The best indication of the tremendous capacity that has been incorporated in a single turbine barrel, and in a single generator, is given by the size of the exhaust opening. This is rectangular and measures 12 x 18 ft. in the clear.

Longitudinally, the barrel is made in two sections. The low-pressure section is of cast iron and is rigidly bolted to the concrete foundation. The high-pressure section is of cast steel and is bolted to the high-pressure end of the low-pressure section. It is hung free of the foundation between the low-pressure casing and the bearing on the high-pressure end of the turbine. It is thus free to expand radially in all directions. At the high-pressure end the bearing is held in guides in such a way that it can slide longitudinally under the effects of varying temperatures.

The unit is supplied with steam through two lines, each 14 in. diameter. These two lines run together in a special, cast-steel, inverted-Y fitting which carries the steam up to the turbine throttle. The exit of the inverted Y, that is, the vertical leg, has an internal diameter of 20 in. While the unit is nominally served by the four boilers located opposite it, crossover headers are so arranged that any of the boilers in the plant can supply it with steam. In practice these crossover headers are always open so that practically all the simplicity of a unit layout is obtained with the security characteristic of a collective layout.

The steam exhausted by the turbine passes directly downward through a short expanding neck into the condenser. This condenser contains approximately 70,000 sq.ft. of surface made up of 1-in. tubes with a length of 24 ft. The tube sheets have a diameter of about 15.5 ft. in the clear, which gives sufficient area to permit the use of numerous generously proportioned lanes to lead the steam to all parts of the surface. This action is assisted by a steam belt which is obtained by setting the tube sheet eccentric in the shell. The steam belt is so shaped and located that it connects the exhaust nozzle with the space directly over the hotwell. This will be referred to later.

LARGEST SINGLE-SHELL CONDENSER

This condenser, like the turbine, is the largest yet attempted in a single shell. It is also unique among condensers of this general class, in that it is arranged for but one water pass. The circulating water enters all the tubes at one end and leaves all at the other end, flowing away over a dam the crest of which is so located as to submerge the highest tubes.

It was feared that with a condenser containing such a deep mass of tubes as this one and with all the tubes carrying cold water, the condensate would be abnormally cooled before arriving at the hotwell. For this reason devices which have been called drain plates were installed. These have been tried in various forms in smaller condensers in the older, or Delray, plant of the company and have been found very satisfactory.

Drain plates are formed by placing light-weight metal plates in the steam space in such positions as to catch the condensate from the upper sections and lead it

---

*Chief of research department, Detroit Edison Co.

[1] For description of initial installation see "Power," Sept. 14, 1915, pp. 388-396.

to the bottom of the condenser without allowing it to come in contact with the tubes in the sections through which it is led. These plates are not intended as steam guides or baffles, and their successful use depends on placing them in such positions that they do not interfere in any manner with the free flow of steam.

In the condenser under discussion the plates are arranged in such a way that the condensate is spilled directly into the steam belt in streams of comparatively small cross-section. It then flows toward and into the hotwell in contact with the steam in this belt. Provision is made to prevent a collection of air over the hotwell and at the lower end of the steam belt, and it is hoped that the condensate will enter the hotwell at a temperature very near that corresponding to the vacuum even under winter conditions.

The condenser is served by two hotwell pumps, either of which has sufficient capacity to handle all condensate made at full load. There are also two circulating pumps. These are 48-in. double-suction pumps and are driven by variable-speed direct-current motors. Each pump has a capacity of 60,000 gal. per min. and can therefore pass sufficient water to condense all steam used at the most economical turbine loading. The second pump will be required only at maximum output, or when the circulating water is above a normal temperature.

The air pump is of the rotative dry-vacuum type and is driven by a variable-speed, direct-current motor. It is arranged for two-stage operation in a single cylinder and has a diameter of 39 in. and a stroke of 30 in.

Coal-Pit Mouth Power Plants

By D. A. Shearer

The present abnormal conditions direct attention to the apparent economy of operating steam-power plants at the coal mines. Long-distance electrical-power transmission has long since passed the experimental stage, and lines carrying hydro-electric power many hundred miles furnish indisputable evidence of the practicability of so distributing power over a large territory.

It has been stated that 35 per cent. of the freight handled by the railroads consists of coal, only 15 per cent. of which is for domestic requirements. This means that the transportation of coal for power purposes is one of the big factors in the high cost of power and is moreover one of the causes of the present great freight congestion. It seems therefore that the establishment of many large central stations directly in the coal fields would mitigate this serious economic condition. The coal fields are situated in a comparatively central position relative to the manufacturing centers of the Eastern States and are within an economical transmission distance if electrical energy is used. By the use of large boiler capacity and large generating units a high degree of efficiency could be achieved and a network of high-voltage large-capacity transmission lines could be extended over the entire eastern part of the United States. This would relieve the railroads of much congestion, dodge labor troubles on the transportation systems, prevent much coal waste in hauling, probably increase the efficiency of many manufacturing plants and would lead to the electrification of many steam railways, with a further saving of coal. The entire output of all grades from any mine could be economically and efficiently changed to electric power.

The coal question will not be settled with the cessation of war, for it is a problem that will remain with us and grow more acute with years. The war has only been the means of drawing attention to economic problems in a pressing manner and a little ahead of the normal schedule. The problems were there before the war and will remain after it is ended, to be considered and perhaps solved by a future if not by the present generation. If the proposed development was in operation now, there would be no coal shortage.

Energy in Revolving Flywheel

To calculate approximately the energy stored in a revolving flywheel, first ascertain (by calculation) the weight of the rim (weight of spokes, etc., is usually disregarded) and its velocity in feet per second (at the given r.p.m.). This velocity multiplied by itself (squared) and by the weight of the rim and divided by the constant 64.32 gives the foot-pounds of energy. For example, a 20-ft. flywheel with a rim weighing 30,000 lb. revolving at 80 r.p.m., or 83.7 ft. per sec., would represent $83.7 \times 83.7 \times 30{,}000 \div 64.32 = 3{,}270{,}000$ ft.-lb. of energy.

Military Road Building

By Sergt. B. C. White

I am writing this from the field to describe an engineering feat by army engineers in building a road called Vanderbilt Ave., from camp to town, requiring several bridges, cuts, fills, etc., to straighten the one time "snake road." Owing to the lack of gravel crushed stone had to be used. Not far from the road there was an old quarry of bastard granite, but the only things in the way of machinery were parts of an old belt-driven drum hoist that Noah may have used. For tools they had one ax, one timber saw, a 2-in. wood chisel and a 2-in. auger.

They investigated the scrap yards in all the near-by towns and found in one place an old locomotive-type boiler and engine mounted on wheels (35 hp.). In another place they found an old stone crusher of perhaps five yards per hour capacity; in another old quarry they found a steam drill or, rather, scraps of several out of which they contrived one that would work some, and an old pump that works well after some little tinkering up. Out of another heap of scrap they got a piece of $1\frac{15}{16}$-in. shaft and a couple of car trucks with the flanges missing on one side. They also begged a few feet of canvas belt that had been discarded in a sawmill. I think there was about 225 ft. of 8-in. belt including bad spots, which were numerous. With this accumulation assembled, they now have 200 ft. of railroad trestle made of bents with rails spiked to headframes at about a 15 per cent. grade, on which they draw stone from the quarry to the crusher. One side of the track is raised two inches higher than the other so the stone car will not jump the track on the side where the flanges are missing. They also have a belt conveyor of 8-in. belt 28-ft. centers running in a trough over 12-in. pulleys at about 100 ft. per min. This belt drops the stone into a pocket from which the trucks are loaded. The conveyor is home-made, as it were—pipe for shafting, the bearings made of old tires when available, but many were made of wood, log ends for pulleys, etc. To make these pulleys they sawed off some pine blocks, bored a 2-in. hole through them, drove them onto the shaft projecting from the hoist and turned them to size with a 2-in. wood chisel. Some of the rails on the road are poles, and all the woodwork is of logs and poles cut in the woods. The railroad is known (locally) as the P. W. & MacD. R.R. (Pop White & MacDougal R.R.) Private Harry Cassey, who is our hard rock man, is better known as "Dynamite Cassey" in the regiment but as Captain Cassey to the natives. Little Willie O'Connors (6 ft. 3 in. tall) is a drill runner. Master Engineer Senior Grade MacDougal, who was formerly master mechanic in the subway, is in charge. The four master engineers in the group posing for their picture are, from left to right, "Pop" White, Dunagan, MacDougal and Conrow.

PREPARING STONE AT THE QUARRY FOR BUILDING A MILITARY ROAD

A Novel Method of Shipping Large Transformers

The method used by the Westinghouse Electric and Manufacturing Co. for shipping three 7500-kv.-a., water-cooled transformers from East Pittsburgh, Penn., to the Northern States Power Co., at St. Paul, Minn., is shown in Figs. 1 and 2. The weight of each transformer without oil is approximately 45,000 lb. Before placing each unit in its tank a corset of wood slats and ribs of steel was built up around it, as shown in Fig. 1, so as to give a circular shape to fit the inside of the tank. The cooling coils were left fastened to the transformer covers, and a bracing arrangement through the center of these coils against the top of the cover, which was in turn braced against the end of the car, served to hold the transformer in place inside the tank.

These transformers were so large that, even when loaded on a drop-frame car, if shipped in the upright position, they would barely be within the maximum height allowable by railroad bridges, etc., even when using special flat covers on the tanks. It was found by the engineering and construction department of the power company that if the transformers were to be shipped in this manner there would be difficulty in getting them over the streets at their destination and up a 30-ft. rise, without crushing through the streets or tipping over. They therefore suggested that the transformers be shipped lying on their sides if possible.

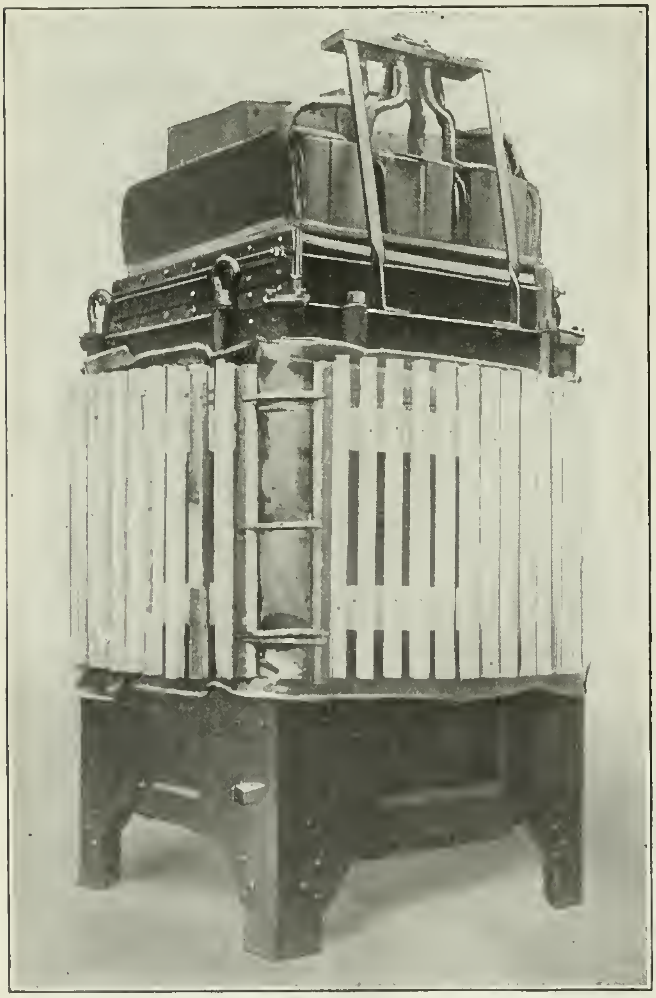


FIG. 1. TRANSFORMER READY TO PLACE IN TANK

The Westinghouse company has an ingenious cradle in which to place transformers when they are to be turned over on their sides. This cradle consists of a platform with one side projecting up at right angles to the floor of the platform. At the corner of the platform there is a rocker. Attached to the top of the side and to the outer edge of the platform are chains of equal length, which, after the transformer is placed on the platform, are attached to a crane. The crane starts lifting, and the chain attached to the platform is the one that carries the weight. This starts to tip the cradle on the rocker and when it is just half tipped, both chains are bearing the weight. As the transformer goes on over in the cradle, the chain attached to the top of the side bears the weight and the one attached to the platform is slack. By this means there is no rough jostling in tipping the transformer.

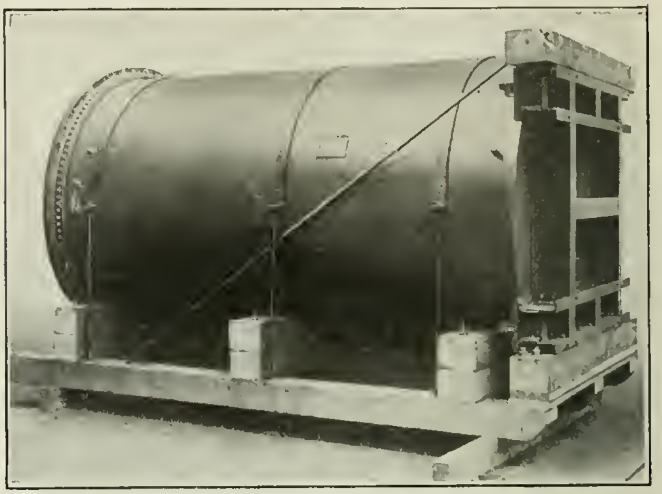

FIG. 2. TRANSFORMER IN CRADLE READY TO SHIP

A cradle arrangement, similar to the foregoing, was built for each transformer and used as a skid in shipment, and in moving the transformers over the streets and up the rise, at their destination. Fig. 2 shows one of the transformers in its cradle ready for shipping.

The transformers arrived in good condition and were skidded to position in the basement of the substation in St. Paul. Through a hole in the main floor a stationary hoist lifted the transformers out of their tanks, the packing was removed and the transformers were again lowered into the tanks and the oil put in; each unit was then lifted to the main floor and put into service.

Superheating steam increases its volume a different percentage for different pressures and temperatures. For example, steam at 100 lb. pressure when superheated 100 deg. is expanded approximately 16 per cent., while 200 deg. increases its volume 30 per cent. and 300 deg. 45 per cent. For any desired case see the steam tables giving the specific volume of saturated steam, subtract this from the specific volume for the degree of superheat and divide by the specific volume of the saturated steam; the result will be the percentage of increase in volume. The same process gives the percentage of difference in volume between two different degrees of superheat. The amount of work steam of a given pressure will do is very nearly in direct proportion to its volume. This is one of the advantages of superheating.

Troubles and Their Remedies in Gas-Engine Ignition Systems

By A. L. BRENNAN, JR.

The various troubles that may happen to either high- or low-tension ignition systems for internal-combustion engines are outlined, and how to go about locating and correcting these troubles is explained.

NEARLY all gas engines are equipped with batteries to supply the primary current to suitable coils to effect easy starting. However, in the majority of cases the magneto is relied upon to furnish the electrical pressure for constant operation. It must not be understood from this that battery ignition is not reliable, for in actual practice it is quite as dependable as that derived from a magneto.

Low-Tension and High-Tension Magnetos

Although there are many variations in the design and construction of magnetos, they can be divided into two general classes—low-tension and high-tension. In regard to the former the current is sometimes utilized direct in connection with a make-and-break igniter or is sent through a coil first and thence to the igniter. In other cases dynamos are used to supply a current for a high-tension system, the current being taken through an induction coil to obtain the necessary potential to overcome the resistance of the air gap. From this it is seen that the principal difference between low- and high-tension ignition is that a low-tension current has not sufficient voltage to break down the resistance of an air gap; therefore, in order to induce a spark, a current must be set up by a closed circuit. This closed circuit results from the movable electrode coming in contact with the stationary electrode of the igniter, which separates at a predetermined time according to the setting of the timer. As the points spring apart, the electric current has a tendency to maintain the circuit already formed, and in consequence an electric arc is formed between these two points for a sufficient length of time to ignite the compressed gas in the cylinder. One of the principal considerations involved in procuring a good spark from a low-tension igniter is to have the points in good repair and forming a complete contact; that is, their entire surfaces coming together. If two very small points only come in contact, the resultant spark will be small and may not be strong enough to ignite the gas.

The chief advantage of low-tension ignition over high-tension is absence of secondary wires and their danger to short-circuit; also, low-tension ignition is practically waterproof. It has several disadvantages, however. The timing of the break is controlled by mechanical means, and the rapidity of the rupture of current between the points is entirely dependent upon the tension of certain springs which operate under detrimental conditions, such as high temperatures. Low-tension magnetos are usually of the simple H type and have but a single coil of comparatively coarse wire. In operation the current induced in the armature fluctuates from zero to a maximum twice in each revolution, and so in order to realize high efficiency the magneto must be so timed that this maximum current will be supplied the igniter at the moment of break in the current. This is usually referred to as synchronism, meaning that the rotation of the magneto's armature and the engine crankshaft coincide in such a way that the maximum potential is utilized at the time of ignition of the compressed gas, as already mentioned. From this it is evident that a magneto of this type must be timed in such a way as to follow out the conditions cited, but this is not the case with continuous-current machines. Generators of the latter type are very easy to maintain and are surprisingly free from any complications.

The commutator should be kept bright by using fine sandpaper. The bearings should be properly lubricated, but care must be exercised against excessive oil, for it has a tendency to creep and thus destroy the insulation of the machine. The brushes should be kept clean and bear with their whole surface on the commutator.

High-tension magnetos can be divided into two classes: (1) Magnetos that merely take the place of battery and timer and deliver current to a coil where the secondary current is produced, and (2) magnetos that comprise in their construction all the elements of generating and distributing a high-tension current, which are commonly called self-contained generators, as they are only dependent upon the engine to furnish the power for their rotation, which of course must be in synchronism with the timing of the engine.

Magnetos of the latter type are subject to about all the troubles that have to do with high-tension ignition of other varieties. But as seemingly complicated as some of the troubles appear, they are in almost every instance easily traced and corrected.

Locating Faults by Elimination Method

A means of locating a fault, commonly known as the elimination method, often proves of value in quickly detecting an existing fault. For instance, suppose the engine is operating from current derived from a magneto; the first step to take is to disconnect the secondary wire from a plug and hold its terminal about an eighth of an inch from top of the latter and notice if a spark takes place. This operation is easily performed while the motor is in operation if the high-tension wires are fitted with terminals that pull off. Considering the setting of the points of a spark plug an eighth of an inch may seem excessive, but the fact should be remembered that the average magneto will produce a spark of this length under atmospheric conditions, but not in the cylinder under pressure, where the resistance offered to a spark gap is considerably more. Misfiring, although often due to faulty ignition, has other causes, such as faulty mixtures or mechanical defects that interfere with good compression.

High-tension generators are necessarily complicated to a certain degree; that is, there are several parts necessary to control and distribute the current, which require more or less attention from time to time. Chief among these may be mentioned the contact points of the circuit interrupters. These points often have a tendency to wear and become pitted and thus make inferior contacts and cause misfiring. In order to overcome this defect the contact points should be cleaned with sandpaper, care being exercised to rub the surfaces flat and not wear away the edges of the contacts and thus reduce their bearing surfaces. If the pitting is very bad, the contacts will probably need filing, which will necessitate their removal. In regard to their repair, there are two conditions to bear in mind: First, to file the points to produce a smooth even surface; and second, to adjust the surfaces of the points at such an angle that when they are together their surfaces will be parallel. It sometimes happens that the points will be evenly repaired, but only make contact on their inside or outside edges. In regard to the correct distance they should be set, it will generally depend upon the make of the magneto. However, the majority of manufacturers supply suitable implements and scales for the adjustment of their machines, which should be closely adhered to. At times dust, dirt or oil will find its way into the circuit-interrupter box and cause misfiring. To overcome this trouble the interrupter box should be washed with gasoline, using a stiff brush.

To Remove Scale Deposits

Continued operation will sometimes produce scale deposits in the circuit-interrupter box, but more often on the distributor segments and brush surfaces, which is usually indicated by misfiring, but this trouble is readily remedied by cleaning the contact surfaces with gasoline.

It is very seldom that a magneto fails to generate a current. Some years ago difficulty was sometimes experienced from the failing of the magnetos owing to loss of magnetism, but this is seldom the case at present.

Any deposits on the contact surfaces of these high-tension generators will invariably interfere with uniform operation, and so they should at all times be kept entirely free from foreign substances. Oil is especially liable to creep and render a magneto inoperative. The only remedy in this case is to take the machine apart and clean it off thoroughly with gasoline. There is one thing to bear constantly in mind when employing gasoline for this purpose, and that is, do not slop it all around, allowing quantities of it to collect around the engine, for the chances are that if you start the engine soon after cleaning the magneto with this fluid, the gasoline at the contact points will ignite and start a dangerous fire. But in any case do not shut down the machine, but turn the gasoline off, if of this type of motor, so that the fuel in the carburetor will be used up in the engine instead of perhaps injuring the generator.

In order to look after a magneto in an efficient way, it must be removed from the engine. However, before this is done, suitable marks should be made that will allow the ready replacement of the magneto without changing the timing.

If a motor is equipped with both battery and magneto ignition and operates satisfactorily on the battery and coil circuit, but faulty operation follows when the magneto is switched into circuit, the trouble is in the second method of ignition, and should not be attributed to other causes. On the other hand, if misfiring occurs when either system is in circuit, it would indicate that probably some fault exists in the ignition, and it should be tested as described in the foregoing.

Particular pains should be exercised to keep all wires free from excessive chafing due to vibration, for short-circuits will result if the insulation on the wires is broken down. All terminals should be kept secure—not only the primary, but the secondary wires as well. The spark plugs should be kept free from oil or moisture, their component parts tight and points bright in order to realize the best results.

Saving by Burning Slack Coal

By F. H. Guldner

While working as a special apprentice for a Middle Western railroad, the writer was called on to determine the fuel and labor costs in a stationary power plant at one of its larger repair shops. Some rather surprising results were found, and in view of the present difficulty in obtaining, and the urgent need of conserving coal, the data showing the savings effected seem timely in again calling to attention principles well known but too often overlooked.

The table shows the amount of coal burned each month, the labor and fuel costs and, in addition, the quantity of each of the three grades of coal used—engine, chute droppings and slack. In the interval given no great fluctuation in output occurred. The cost of labor for the various months was nearly uniform excepting the period from the latter half of December, 1914, up to and including March, 1915, during which time the old duplex-steam air compressor was replaced by a cross-compound two-stage compressor of high efficiency and a feed-water heater was installed. While the change was being made, air was furnished by a battery of locomotive air compressors of relatively low efficiency; this accounts for the high labor and fuel cost during these months.

FUEL ECONOMY EFFECTED

		Coal Burned in Tons				Total Coal
Month	Labor	Engine	Chute Droppings	Slack	Total	Cost

July	567.92	329 90		385 55	715 45	1,056 44
August	587 99	85 00		482 85	567 85	731 84
September	594 46	84 00		477 05	561 04	692.76

In April, 1915, it was decided to change from engine coal costing about $1.85 per ton to slack at $1.10.

It was feared that it would be impossible to maintain the required steam pressure, but results dissipated this fear. About 164 tons was burned that month, and gradually the percentage of slack was increased and the amount of engine coal decreased until in August and September, 1915, the slack was nearly five-sixths of the total coal burned. About this time the writer was transferred to another position, and he was unable to get later figures. Those given, however, will be sufficient to illustrate the object of this article. By comparing the average (May to September, 1914) monthly coal cost with a corresponding period one year later, it will be noticed that it was reduced from $1956.77 to $1047.86, or 46.5 per cent. A more striking example would be to compare the average coal cost in August and September, 1914, when the old air compressor was in use and practically all the fuel was engine coal and little slack, with the same months in 1915, when the feed-water heater and the new compressor were in use and the coal conditions reversed to nearly all slack with a little engine coal. The average in 1914 for these two months was $1956.94, against $712.30 in 1915, a decrease of $1244.64, or 63.5 per cent.

This was accomplished by an investment of approximately $10,000 for the air compressor, $2000 for the feed-water heater and $6000 for removing the old compressor and installing the new equipment—a total of about $18,000—less the salvage value of the old compressor, which was sent to a smaller shop for use. No doubt there are many plants, not only in the railroad field but also in public utilities, manufacturing, etc., whose coal consumption could be materially reduced by the use of more efficient prime movers and the substitution of cheaper coal. Substitution, when possible, enables the conserving of the better coals for purposes that do not permit the use of poor coal and at the same time is profitable.

Spliced Conductors in Conduits

By B. A. Briggs

The National Board of Fire Underwriters' Rules specify that a splice in a conductor must not be pulled into a conduit. The wisdom of this ruling appears to be hard for many to appreciate. Nevertheless, that it is based on sound judgment has been proved in many cases by cable grounding on splices that have been pulled into conduits. One case in point that came to the writer's attention was that of a small rotary converter that blew one of its fuses infrequently for several months before the cause was discovered. All tests that could be made indicated nothing wrong during this period. The trouble was caused by a spliced cable, in a conduit running from the machine to the switchboard, flashing to ground at irregular intervals and each time burning itself clear without leaving any trace of the trouble except blowing the fuse. At last the conductor became grounded, and then the trouble was easily located and repaired by pulling out the old cables and replacing them with new ones.

In another case, in what is supposed to be one of the best isolated-plant installations in this country, the shunt-field winding of one of the machines of a three-wire balancing set was discovered to be dangerously hot, after the machine had been standing idle for about twelve hours. Investigation showed that one side of the shunt-field winding was connected permanently to one of the 220-volt busses and that one of the main cables running from the switchboard to the machine was grounded in such a way as to leave the shunt-field winding connected across the 220-volt circuit.

In this plant the cables from the switchboard pass down through bushings in the floor into a large $\frac{3}{16}$-in. iron duct, about 6 in. deep by 2 ft. wide, which runs the entire length of the switchboard. From this duct the cables run in conduit to the various circuits and machines. It was in this duct that the ground was located on the cable. The cable, like a lot more of them in this duct, had been cut too short and was spliced out to reach up to the terminals on the back of switchboard. In making the splice, points of solder were left, or maybe some of the ends of the wire were not properly forced down into the splice, so that in time, because of the vibration of the cable against the bottom of the duct, the insulation was broken down and a ground occurred. Some severe arcing must have taken place, since, as the illustration shows, considerable of the splice is burned away; also a large hole was burned into the $\frac{3}{16}$-in. iron-duct wall. This splice from all appearances had been thoroughly insulated by both rubber and friction tape, and could not have been subjected to any of the abuses that it would receive if pulled into a conduit; nevertheless, it failed as many other cable splices have failed in conduits. Consequently, there is but one safe rule: Obey one of the mandates of the National Electrical Code and do not pull spliced conductors into conduits.

CONDITION OF SPLICE AFTER BURNOUT

Burning Oil or Tar in Combination With Coal

The coal shortage has caused most engineers to consider using whatever fuels are available whether they be the various grades of coal, fuel oil, tar or bagasse, and to provide an auxiliary fuel should their coal give out. Dr. W. N. Best has lately brought forth an invention which makes possible the quick change from coal to oil or tar and vice versa. The usual location of an oil burner is at the ashpit or the fire-door. This invention leaves these doors free for use without disturbing the burner or the piping. It is sold by W. N. Best, Inc., 11 Broadway, New York City.

Referring to Fig. 1, it will be observed that the liquid-fuel burner is mounted on the side or front wall of the boiler furnace. Fig. 1 shows that the burner is in the operating position. Fig. 2 shows it in the idle position as it would be when no liquid fuel at all is being burned or when fuel on the grate only is burning. Notice that by moving the operating lever to the up position, the sliding gate closes the opening in the side wall so that no air is admitted here while the liquid-fuel burner is idle. It will be observed, also, that should it be desired to operate at rather low boiler capacity, the sliding gate may be operated so as to admit a little air, or rather so as to admit the quantity of air required by the amount of fuel being fed. Greater capacity may be had by opening the sliding gate more and more and feeding greater quantities of oil and steam for atomization.

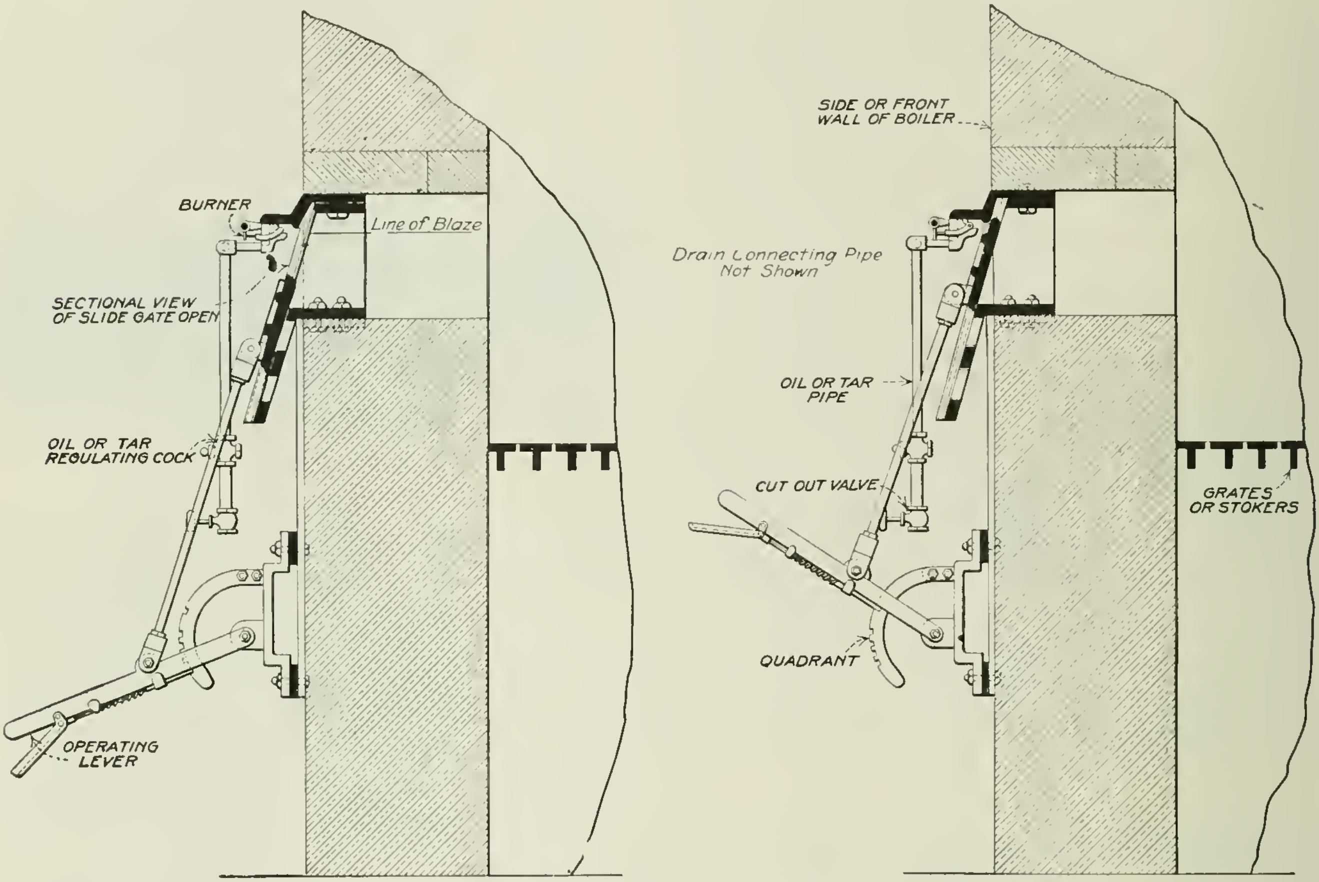

Fig. 1

Fig. 2

LIQUID-FUEL BURNING APPARATUS FOR USE IN COMBINATION WITH COAL
Fig. 1—Burner in Position for Use. Fig. 2—Burner Shut Off and Opening in Furnace Wall Closed

Readers will, perhaps, remember that an oil burner of similar design is in general use. With the old-style burner equipment designed by Dr. Best no provisions other than a few loose brick were made for closing up the openings in the side or front wall when the burner was not in use. This, of course, means that great quantities of excess air are admitted to the furnace when the oil burner is not being operated. With the new device the opening is closed tight when the burner is idle and is adjustable to accommodate various capacity demands. The apparatus lends itself to the use of auxiliary fuel.

Manifestly, no alterations are required to the boiler or the furnace to attach the burner. If liquid fuel is burned, the grate may be covered with ashes for protection.

The burner is one wherein the oil, tar or liquid-fuel opening or outlet is at right angles to the direction of the steam outlet; that is, the steam used for atomization. This steam sweeps directly over the oil or liquid-fuel outlet, thus keeping the outlet free of the carbon so frequently found on burner tips.

Where tar is burned, the fuel may gravitate to the burner from a tank mounted on top of the boiler or in an elevated and warm location in the boiler room. Heating coils are provided so that the fuel may be heated nearly to the point of vaporization.

One burner is used per furnace regardless of how large or how small the furnace may be. This is true for oil or tar. The atomized oil issues from the burner through a diverging groove in the burner tip. The flame is flat and, depending upon the shape of the groove, is long or short.

The oil or liquid-fuel control valve is provided with stops which may be set by the boiler-room engineer after he determines the limit of open position of the valve, thus preventing the fireman from exceeding this limit.

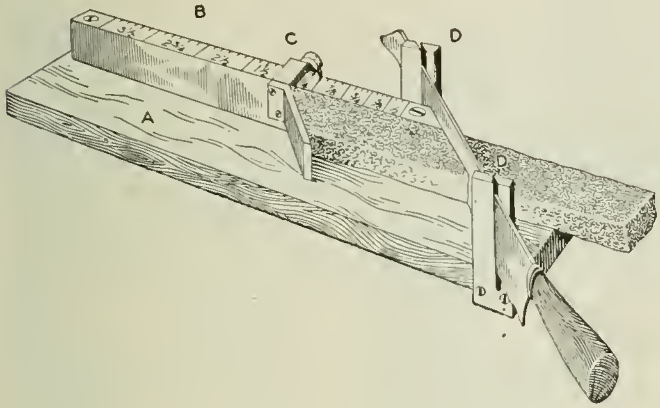
A Handy Packing Cutter

By J. A. Lucas

Many methods of cutting piston-rod packing have been published in *Power*, but I have never seen anything similar to the tool shown herewith.

The base A is made of wood 1 in. thick, 3½ in. wide and 21 in. long. The gage bar B is about 16 in. long and is made of hardwood. One end is cut to an angle of 45 deg. The sliding block C is part of an old motor brush-holder with a piece of $\frac{1}{16}$-in. iron bent to an angle of 45 deg. riveted to it. The bar *B* is made an easy sliding fit for the block, which is clamped to it by the thumb-screw placed on the back side. The knife guides *D* are made of $\frac{3}{16}$ x 3-in. iron and are about 4 in. high, with the slot cut on an angle of 45 deg. and set so that the knife will just clear the end of the bar *B*. A common bread knife with scalloped edge is used for cutting the packing. The top of the bar *B* is graduated so that the distance from the knife to the stop, when set at a certain number, gives the length of the circumference of a circle of that diameter, plus $\frac{3}{16}$ in. for expansion.

To lay off the graduations on the bar, get a table of circumferences of circles, and to the length of the circumference add $\frac{3}{16}$ in. for expansion up to 2 in. diameter; $\frac{1}{4}$ in. from 2 to 3 in. diameter, and $\frac{3}{8}$ in. for larger diameters. After measuring off their distances on the bar, stamp them with small figures or other suitable marks. The distance from the knife to the 2-in. mark by this method is $6\frac{1}{2}$ in.; to the $2\frac{1}{2}$-in. mark, 8 in., etc.



DEVICE FOR CUTTING PACKING

To operate, first get the diameter of the rod, which is, say, 2 in. Add the size of the packing, which in this case is, say, $\frac{1}{2}$ in., amounting to $2\frac{1}{2}$ in. This is the diameter of a circle passing through the center of the packing ring. Set the gage at the $2\frac{1}{2}$ mark on the bar, and cut the first end at an angle in the slot; then butt the packing against the stop *C* and cut off. This would be the length for a good fit, with the right amount of room left for expansion.

Vibration Effects on the Operation of Electric Generators

By R. K. Long

Vibration may be due to causes internal or external to a machine, or both, the result being cumulative or otherwise. The commoner causes of vibration are unbalanced rotors, bent shafts, improper foundations and fastenings, excessive speed, excessive and fluctuating loads, vibration of the structure housing the machine, its periodicity of vibration being superposed upon that of the machine. Some machines show less vibration with no load than with load. Others again vibrate only when running light or at a definite load, still others only with load changes. The effects of vibration upon direct-current machines is probably more serious than on alternating-current.

Vibration in direct-current machines may cause loose connections and open-circuits. Abrasion also often occurs, the effect of which causes short-circuits and ground in the windings. Brushes may chatter, causing sparking, poor commutation and rapid deterioration of the commutator and brushes, with accompanying higher cost of upkeep, as well as interfering with the capacity and regulation of the machine. With certain classes of brushes increased heating, due to sparking and unequal current distribution, causes the lubricant to exude from them, gumming the commutator and permitting carbon dust to collect, causing flashovers and making the brushes stick in the holders.

A bent shaft in setting up vibration also causes unequal air gaps as it revolves, which may result in overheating the equalizer rings or taps in some form of armature winding. Bad commutation results in any case; flat and burnt spots may appear at definite spacings around the commutation. A bent shaft may damage the insulation or cause breaking of armature conductors; unequal wear of bearings may occur, due to shaft out of alignment. Throwing lubricating oil may occur, which may soon eat into the mica of the commutators, doing serious damage, for oil is the arch enemy of mica.

Alternating-current generators are usually less influenced by vibration than direct-current machines, owing to the absence of the commutator. Where the units have a direct-connected exciter, however, they may suffer in the same way as the direct-current generators already referred to. Excessive vibration has often resulted in grounding and short-circuiting of the field winding of high-speed turbo-generator units, the result of which is that the field current is increased, causing overheating and finally failure, by burning out the entire field winding.

The stator, or armature, of alternators also suffers from vibration. Conductors work loose, enabling them to move with load changes, causing deterioration of the insulation and failure under normal potential. Another result of vibration sometimes encountered in large turbo-generators is that the emergency steam valve closes accidentally, shifting the generators' load to other machines—a somewhat serious matter where the load may be 20,000 kv.-a. or more. Vibration is perhaps more likely to occur in the rotating elements of steam-turbine units than in other types, because of the accumulation of scale. This is, however, a transitory condition.

In one case a machine was installed upon a girder so that it wabbled from one side to the other with load changes, a matter easily remedied by leveling the machine and grouting, at the same time solving a difficult commutation problem. Several boosters have run away with varying degrees of damage on account of broken field coils, due to vibration. Bent shafts have added their quota to strange voltage drops for no apparent reason, although brushes sticking in the holders may have helped in this case.

There are many degrees of vibration, causing as many effects, some obvious and others not so apparent. All unnecessary causes should be eliminated because vibration is always objectionable, since it shortens the life of materials, wastes energy in the form of noise and needless motion, which lowers the efficiency of the apparatus and increases the difficulties and cost of operation. Provided a machine is properly designed, installed and maintained, most of the troubles enumerated may be prevented, and prevention is always better than cure

The Coal Supply and the Railroads

WITH the extraordinary demand for fuel consequent upon the war the price of coal went to exorbitant figures. A contract was no protection, for the contractor simply avowed his inability to carry out his agreement, and those who had to have coal—and that means everybody who bought it, for nobody buys coal for bric-a-brac—had to go out in the market and outbid the others for it. The consequence was that notwithstanding the alleged inability of contractors, handlers and dealers to get coal, there was more coal than ever mined and sold, but at greatly increased prices.

And then the people spoke up and said, through their President: "This profiteering must stop. We will pay you producers so much per ton for the coal at the mine. The railroad haulage is fixed. You jobbers and retailers can have so much per ton"; and it looked as though the consumer was going to get his coal for cost plus a more or less fair profit.

But notwithstanding the price allowed per ton at the mine was away above what they had got before the war, the producers, or some of them, averred that they could not produce at that price; and the long-suffering people raised the price still higher with an intimation that if the producers could not and did not produce at that price, they would take over the mines and do it themselves.

And then it was found that the greater part of the coal had been already sold on contract at prices above those fixed by the Government; and again the long-suffering people, standing abashed before the sanctity of contract and the horror of upsetting business, said: "All right, we will pay these prices that somebody has contracted for us, for their payment will come upon us in the final analysis, but only on the contract coal. Let the free coal come along at the prices we have fixed."

But the price did not go down. The cost for railroad haulage was controllable, but there was a shortage of bottoms and of tugs, and prices for water transportation went soaring. When one must have coal or shut down and another has coal and wants to turn it into the most money that one's necessity will compel him to pay, it takes more than a Government dictum without penalties for its evasion to keep them apart. A bet that the Washington Monument will fall in two weeks; an intimation on the part of the coal merchant of his willingness to part with a treasured desk weight, a bull pup, an old white horse or some similar object of virtu upon sufficient inducement, offers an opportunity for the purchaser to pay the difference between the price at which the Government has said the dealer must sell and that which is fixed by the buyer's necessity and the dealer's cupidity. Speculators offered to furnish coal if they were permitted to bill at the Government price and collect at their own. Contracts were dated back to precede the Government order. Wagon mines sold coal at the Government price, but on condition that they be allowed to haul it; and made up in the haulage charge the extortion which the President's order was intended to inhibit.

And still the prices do not go down; the free coal does not come along and the shortage has increased until factories are shut down, ships lie in the harbors with empty bunkers, while the goods that they should transport glut the terminals and clog the railroads. War work is hampered, public utilities are crippled, hotels are without light and heat, and long lines of shivering men, women and children stand waiting for hours for the privilege of buying a pailful of coal at ten dollars a ton. The death rate from pneumonia in New York has gone up enormously.

Whose is the fault and what is to be done about it? The anthracite producers say they cannot produce on account of labor shortage, and they send, to a market which is in a condition where it must take anything, the ejecta of more exigent years, burdening the already overloaded transportation system with tons of worthless dirt and slate and ash sold at the price of good coal. Trainloads of this coal, large and small, good and bad, were held almost within sight of New York until shifting engines could pull out of the maze cars bearing particular numbers consigned to the particular man whose barge was ready, because, they say, some ridiculous Government regulation decreed it so. The Administration has now decreed that the coal shall be pooled and kept moving.

The bituminous producers claim that they can mine, with the plant and labor available, more coal than the railroads can furnish cars to take away and that they are filling cars as fast as they get them. The mine is the best storage for the coal until it can be shipped. The railroads say that they have cars enough, but that their systems are blocked by priority orders, excessive demands upon their equipment and lack of motive power.

It would take 5000 locomotives to replace those worn out in the United States every year. In the month of October there was ordered in the whole country just *one*. In the last five years the number ordered per year has been on an average 2391 and has never exceeded 3467; and just previous to the war the shops of the American Locomotive Company were almost shut down for lack of orders. With a mild winter and an ordinary amount of traffic the railroads might have pulled through again. A season of exceptional severity and the extraordinary traffic due to the war have swamped them. If the Government had been operating the railways and had gotten them into this self-confessed condition of impotency, Government ownership would have been indicted as long as the memory of it should last.

It is useless to inquire how we drifted into this condition, except as the inquiry may help us to avoid doing it again. The thing now is to get to running again. The combining of the railroads into a consistent unit under Government control, with the resources of the entire country back of them, was the logical first step, and if the railroad managements with whom the operation of the roads is still left will concentrate on getting the most that is possible out of them under the new coöperative conditions instead of worrying about when they are going to get them back or trying to discredit Government operation, the task will be easier. In the meantime let us not blame the Government if it cannot make a run-down cripple do a giant's task.

Developing the Water Powers

THE most insistent of the conservationists in and out of the Government have always been ready to permit private capital to develop the water powers upon terms which would insure the complete return of the investment with interest and a fair profit upon the business done, subject only to such risk as attends the development of any water power outside of Government control. After years of hampering argument and struggle between those who sought to obtain the control of the water powers and those solicitous for the rights of the people, the Administration has prepared a bill which, in view of a public sentiment created by months of vigorous propaganda by chambers of commerce, industrial committees and similar organizations, is likely to pass. This bill, while an improvement on former measures, does not appear to us to be without objection.

Any bill, while guarding absolutely the safety of the investment against confiscation or embarrassment by Government interference, should provide for the retaking of the privilege by the Government when the people need it or conditions make it advisable. This bill gives an irrevocable grant for fifty years, at the end of which time the Government "shall have the right" to take the property, not by paying back what the investor put into it, less what he has paid himself back besides his fair profit, but by paying "the fair value not to exceed actual cost of the property taken." Inasmuch as the fifty-year grant is insisted upon in order that the bonds may be retired out of earnings within the life of the grant, this would appear to allow the investor to recover his investment out of earnings, and then collect it again when the plant is sold.

A "fair value" is indefinite and indeterminable. The price of recapture should be fixed at actual investment less depreciation. Depreciation is simply retired investment and should be deducted from the capital account, leaving the amount upon which interest is allowed and which must be paid upon recapture.

"The United States shall have the right" to take the plant over. Who is going to exercise this right or determine that it shall be exercised—the President, the Congress, the Commission, or who? Unless the provocation is great, there will be no concerted movement on the part of the consumers, and a Congressman would have to be a radical spoiling for a fight to undertake the recapture on his own initiative.

We should like to see the bill stipulate that current should be sold at cost plus a fair (and stipulated) profit. This involves an oversight of the issue of securities and of expenditures to insure that all the investment incurred appears in the property in either material or service, and is essential also to establishing the recapture value. The Commission established by the bill is empowered to prescribe rules for uniform accounting, to examine books and to require full statements as to cost of operation and the production, transmission and sale of power, to hold hearings in connection with the regulation of rates or service; but the Commission has no rate-making power except for interstate business or in states where no such regulation exists. The delegation of such powers to state public-utilities commissions is not likely to be so positive and satisfactory as a specification of the allowable rate of profit and the methods of its determination in the grant.

Wherever licenses to states or municipalities are mentioned, it is prescribed that the power is to be generated solely for state or municipal purposes. Does this preclude the obtaining of a grant by a state or municipality for the purpose of generating power for the use of its inhabitants?

Altogether, the bill is a great improvement upon former attempts, but we should like to see it more specific and positive in the particulars mentioned.

Government Control of Fuel Oil

THE President's fuel-oil proclamation of February fourth, which went into effect the following Monday, or the eleventh, now gives the Government control of the transportation and distribution of the two chief fuels. Considering the troubles that producers, shippers and consumers of fuel oil have been having, it is assumable that they welcome the Government's action.

Take New England, for example. Oil displaces about one million tons of coal per year at the present consumption. It is used in many industries vital to the prosecution of the war. The shippers of the oil and the consumers have viewed with no small measure of alarm the commandeering of oil-carrying ships by the Government. One company transporting great quantities of oil to New England ports has six ships left out of a total of twenty-one, the Government having taken the difference. Much of this oil goes to Providence by water and then by rail inland to the points of consumption. The serious congestion of the railroads has caused excruciating delays of tank cars both going and coming. Lately, one car was six weeks from Providence to Lawrence, Massachusetts, and return. There is not an abundance of oil-tank cars even for normal conditions of demand and transportation. Now fuel oil will likely have a priority commensurate with its value as a war essential.

The situation had become serious for New England, and the President's proclamation is by no means premature. To cite another case: A consumer of fuel oil in Boston has been compelled to transport oil for his plant by motor truck from Providence to Boston because the shipper could not get oil beyond Providence. The truck or trucks had to be kept going night and day. The expense is obvious. Doubtless one of the first moves of Mark L. Requa, new head of the Oil Division, Fuel Administration, will be the elimination of conditions that impose such hardship upon the shipper and consumer.

The priority list for deliveries of fuel oil as announced from Washington are, in the order of preference, as follows: Railroads and bunker fuel; export deliveries or shipments for the United States Army or Navy; export shipments for the navies and other war purposes of the Allies; hospitals where oil is now being used as fuel; public utilities and domestic consumers now using fuel oil (including gas oil); shipyards engaged in Government work; navy yards; arsenals; plants engaged in manufacture, production and storage of food products; army and navy cantonments where oil is now used as fuel; industrial consumers engaged in the manufacture of munitions and other articles under Government orders; all other classes.

Plants not making munitions or other articles under Government orders are therefore twelfth on the list. The order of preference appears eminently fair. If the head of the Oil Division gets the right kind of coöperation from Mr. McAdoo and if the Navy Department and Shipping Board will not divert more ships from our coastwise oil trade than extraordinary emergencies demand, Mr. Requa will be free to devote his time to moving oil instead of needing all time available to care for complaints, as the state and local fuel administrators have to do.

Why Not Have an Ash Inspector?

TODAY we have fire inspectors to see to it that the means used for generating, transmitting and utilizing power are not allowed to become a fire hazard and endanger the safety of the community. We have boiler inspectors, in some cases backed up by the law of the state, whose business it is to have all boilers maintained in such condition that they will not become a menace to life and property. We also have fuel administrators, both national, state and municipal, whose good purpose it is to control the destiny of the nation's coal pile. All this may be very commendable, but how about what happens to the coal after it goes into the boiler room?

An inspection of the contents of the ash cans on the curb waiting to be removed from in front of many of our large buildings would indicate that many plants have coal to throw away. The time when we can afford to allow coal to be used in such a way that a large percentage of its carbon content is thrown away in the ashes has long gone by. Although the fuel supply will last for hundreds of years hence, nevertheless it has been the bitter experience of millions in this country and abroad recently that it is almost impossible to obtain fuel at any price. Landlords, using the coal famine as a pretext, have allowed their tenants to suffer for the wanted heat, and some of the traction companies have tried heating their cars with animal heat, while the public paid for something they did not get. Yet, after all we have been experiencing from a coal shortage, it is difficult by inspection to tell whether the contents of many of the ash cans waiting removal from in front of a number of our city buildings are intended for coal or ashes.

If the owner of a plant, whether it be for power or for heating purposes, is willing to allow a large percentage of the coal thrown into the boiler furnace to be carted away in the ashes when the nation is facing a coal famine like the present, it is time that some pressure be brought to bear from the outside by someone who has the power to have the conditions remedied or to cut off the offending ones' coal supply. One of the ways to get at this would be to enact a law limiting the carbon content of the ashes from boiler furnaces to a certain percentage and to appoint inspectors to investigate the ashes coming from every plant and see to it that the law is being complied with.

As long as the manner in which a power plant was operated did not in any way seriously affect the community, how it was run was very largely nobody's business but the owners; but when it has come to the time when it means that coal wasted in these plants is coal that somebody else seriously in need of it must go without, then it becomes the public's business how even a private plant is run. Many of the central stations throughout the country have been forced to curtail their output for certain illuminating purposes, consequently suffering a loss of revenue, in order to save coal for private industries and heating. In justice to these public utilities which have had their output restricted by Government control to conserve the nation's fuel supply, the same Government should see to it that the fuel used in private plants is utilized in the most economical way and not thrown out in the ashes.

That the electrical interests have been alive to the opportunities afforded by the exceptional fuel situation is evidenced by the general advice given by fuel administrators to power users to conserve fuel by patronizing the central station. The advice is honestly and disinterestedly given, but the shutting down of many an isolated plant would mean a waste rather than a saving. Many power users who would otherwise have put in or continued their own plants have been driven to adopt "street service" by the uncertainty of the fuel supply or the impossibility of getting deliveries on apparatus. On the other hand, many owners of plants depending upon central-station current and idle for the want of it are hustling for steam, gas and oil engines.

Now or never Rhode Island coal has its chance. There is said to be a large quantity of it above ground as the result of Henry M. Whitney's attempt to develop the mines some years ago. The coal is hard, almost graphitic, but will burn, and might be used to advantage mixed with bituminous. It was of these mines that William Cullen Bryant wrote,

> That men might to their inner caves retire
> And there, unsinged, abide the day of fire.

An expressive statement of the purpose of the American Association of Engineers, emanating from its secretary, is that it is to put scientific management behind the young engineer and get him into the place where he belongs in a nation organized for over-all efficiency.

At the Kansas State Agricultural College there are one hundred and fifty women studying electrical engineering. Many women are employed in the central stations of Europe. Welcome to our ranks.

Correspondence

Losing Water from a Heating Boiler

The attendant of a small heating plant had considerable trouble in keeping water in the 60-in. diameter boiler over night, and although it was filled nearly full it was necessary to put in considerable city water each morning before starting up. On one occasion it was impossible to get any heat in the system at all until it was drained, as it was full of water.

At one time some radiator repairs had been made and the steam fitter had, as a matter of safety, closed the stop valve on the return pipe and the attendant had closed the stop valve over the boiler. When the attendant opened the stop valve on the top of the boiler, he forgot to open the valve on the return pipe, and the condensed steam filled the heating system full of water, as it could not return to the boiler. When the stop valve on the return pipe was opened the boiler filled and some of the water had to be blown out through the blowoff. This freed the heating system, but the next morning the water was again out of sight in the gage-glass and considerable water had to be supplied.

It was noticed that there was water in the ashpit, and it was supposed that it seeped through the ground. Investigation showed water trickling out through the brickwork just below the grates on the water-column side. The boiler was shut down, the brickwork was torn away, and just back of the water column the bottom connection from the front head to the water column was found badly corroded externally; and although the brickwork was dry at this time, it evidently had been wet during the summer months while the boiler was out of service, as it was customary in the spring to play the hose over the top of the boiler brickwork to settle the dust before brushing it down. Probably because of this considerable moisture remained in the side walls and caused corrosion at the pipe connection. After repairs were made, the boiler gave no more trouble for several days, when the water again disappeared from the boiler and the radiators and pipes began to hammer furiously.

Investigation showed that the attendant had closed the stop valve on the top of the boiler while making a radiator repair, and he either forgot to close the stop valve on the return line or else depended on the check valve to hold the water in the boiler. But the check valve was out of order and allowed the water in the boiler to back up in the return pipes to the radiators, thus causing the water-hammer. Opening the stop valve on the top of the boiler equalized the pressure, and the boiler quickly filled up. Luckily, there was but little fire in the furnace or the fusible plug would have been melted.

The check-valve disk was found to be disconnected from the hinge plate, the nut holding it being missing; one side of the bolt end was also broken off. Someone had slotted the end of this bolt on the back of the valve disk and, after putting on the nut, had driven a blunt chisel into the slot to spread the end of the bolt and thus prevent the nut from working off, but in doing so had fractured the metal on one side, which had eventually come out, leaving the nut loose, which also dropped off and then the disk dropped from the hinge.

It is always best to close the stop valve on the return pipe before closing the stop valve on the steam line, but do not forget to open it. If it is forgotten, however, the water will not escape from the boiler very rapidly by evaporation and it will be noticed at the water glass before the water becomes too low.

In one instance the floor in front of the boiler was covered with several inches of water one morning. The blowoff pipe passed beneath the floor of the next room, which was about 30 in. higher than the floor in the front of the boiler. The blowoff-valve stem had been leaking, corrosion had eaten the pipe through, and water escaped from the boiler overnight.

Where pipes go through a brick wall, they should pass through a sleeve of a larger diameter, and underground blowoff pipes should not be buried, but should be surrounded by a box to keep the earth moisture from the pipes to prevent corrosion. R. A. CULTRA.

Cambridge, Mass.

[These experiences of a man who evidently did not know his business emphasize the need of a license law to protect such men and others against their own ignorance. The owner of the plant evidently hired an inexperienced man because he was cheap, and at the same time ran a very favorable risk of ruining the boiler by burning and the piping system by water-hammer, to say nothing of a possible boiler explosion.—Editor.]

Inadequate Provision for Expansion

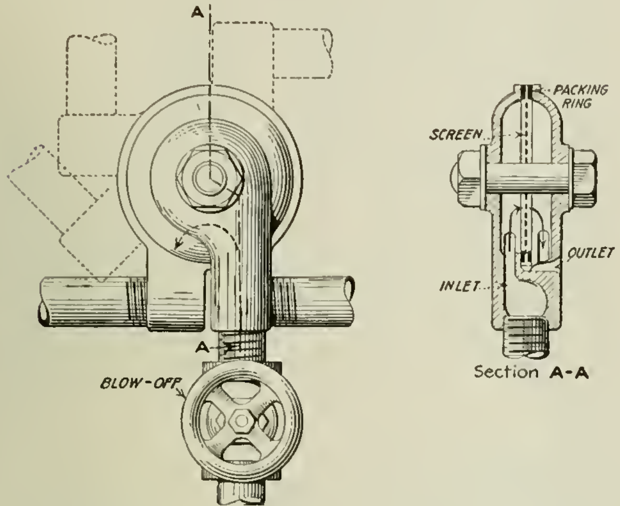
A practical demonstration of the necessity of allowing liberally for the expansion of a pipe line to carry steam came under my observation several years ago. The 2-in. pipe line was intended for use in emergencies, to serve a tank pump when the boilers were off in that part of the plant. About 400 ft. was laid under ground, ending with a tee to make the turn into the building and a nipple and valve for a bleeder, in a shallow wooden box about 2 ft. square.

When steam was turned on slowly, the engineer went down the line to close the bleeder, but he found the pipe had lengthened and pushed the valve and nipple through the side of the box, so the only thing to do was to shut off and wait for the line to contract enough to take the nipple out and screw a plug into the tee and do the draining at a point beyond. All the expansion had gone one way because of the considerable pitch downward in that direction. J. LEWIS.

New York City.

Strainer for Pipe Lines

Attention is frequently called to the necessity of connecting strainers to the inlet piping of steam traps and other such apparatus, and considerable trouble is caused at times by dirt getting into them. This led me to design a strainer in accordance with my own ideas, as shown in the illustration. It can be put in a line in place of a union or a pipe fitting, can be used to form any desired angle and is extremely simple.

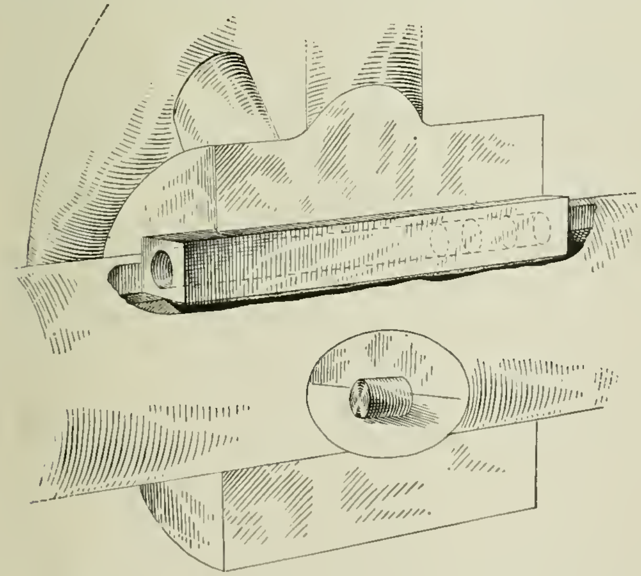


NOVEL TYPE OF STRAINER TO GO IN PIPE LINE

Hasbrouck Heights, N. J. GEORGE J. LITTLE.

"Buttoning a Key"

This is a means of tightening a key in its keyway when it is difficult to remove it, as in some cases it means dismantling a lot of parts to take a key out. Drill the key lengthwise, being sure not to cut through the sides of it, then cut off pieces of round steel about half an inch long and a little larger than the hole and drive them in separately until they fill the hole solid. When the job is done, you have as tight a key as you ever had. GEORGE H. DIMAN.



KEY DRILLED AND TIGHT-FITTING PLUGS DRIVEN IN

Lawrence, Mass.

Three Motors Heated

The connections for two single-phase transformers when operated open-delta from a three-phase circuit are shown in Fig. 1. The voltages of the secondary side are displaced 120 deg. from each other and are of the same value, therefore any three-phase device that is operated from the secondary will, under normal conditions, be subjected to balanced three-phase voltages.

A construction contractor complained that three three-phase motors which he had just started on a new job heated so badly when operated for only five minutes without any connected load, that it was impossible to use them. He further stated that their operation had been entirely satisfactory on the preceding job.

The fact that all the motors heated in this case, whereas none had ever heated before, suggested trouble in the 220-volt service line. As there was no voltmeter available, the voltage at the motors was roughly measured by means of two 110-volt lamps connected in series. From the middle to either outside wire the voltage appeared to be about normal, but between the two outside wires the voltage was abnormally high. It was determined that in using supply transformers that were made by different manufacturers, the two secondaries had been connected with the wrong polarity, as indicated in Fig. 2. Reversing the polarity of one transformer not only increases the value of the voltage between the outside legs 1.732 times over that of one phase, or in this case 220 × 1.732 = 381 volts, but also changes the phase displacement between the resultant voltage across the two transformers and that of each unit from 120 deg. to only 30 deg. As a result of the error, not only was one phase winding of all motors subjected to 73 per cent. overvoltage, but the torque characteristics were so much modified that the rotors, even when free, would not come up to full speed. E. C. PARHAM.

Ideal Power-Plant Location

Mr. Dow. in his article on "Production of Electricity by Steam Power," in *Power* of Dec. 11, speaks of the location of power plants, and this brings to my mind the ideal location of a small country plant. Of course they wanted to get as near the center of distribution as possible, and in looking for such a site found a creek running through this section. They decided that by making a reservoir near a railroad they would be sure of water and also be accessible to a coal supply. After excavating a few feet, solid rock was found, which was blasted out and considerable of it used in the construction of the plant.

So here we had an ideal location, with plenty of water, and in making the reservoir we secured enough stone to build the plant, which was erected within one hundred feet of the main-line railroad, with the plant located in about the center of distribution.

New York City. D. R. HIBBS.

Lamp Bank as a Rheostat

In connection with electrical work there are innumerable instances where some form of rheostat is required for reducing the current in a constant-potential circuit. There are many forms and types of rheostats, using metallic or carbon resistance units or a liquid; but they may all be classed under one of two categories, those for continuous service and those for intermittent service. Rheostats used in charging storage batteries or in motor circuits for speed control must be designed for continuous service; rheostats used for starting duty only need be designed for intermittent service.

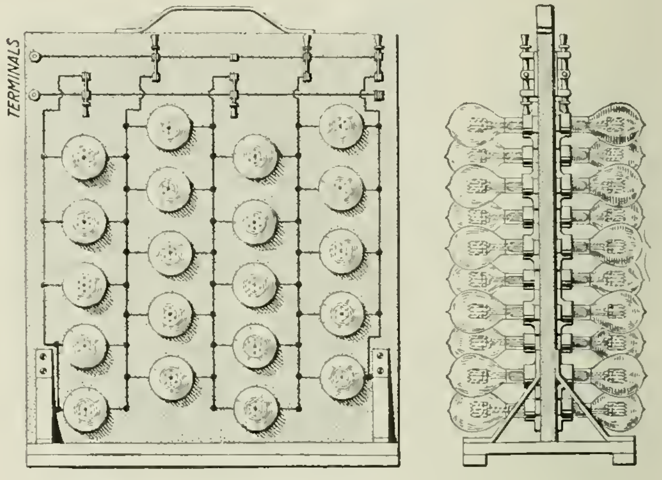
The ordinary electric lamp offers a convenient means of designing a rheostat for continuous duties, which is easily made from material readily obtainable almost anywhere.

The figure shows a rheostat that is made up of 110-volt lamps arranged so that they may be used on 110, 220 and 440 volts. The shape and size of such a rheostat depend upon where it is to be used. For use around a power station or an industrial plant, lightness and portability are important features. For this purpose a ¾-in. wood board treated with asphaltum paint or, better yet, a piece of asbestos board, or slate if the rheostat is for stationary purposes, may be used. At one end of this board are placed five 5-amp. single-pole knife switches, two of them double-throw and three single-throw, mounted on porcelain bases, which should be left on, since the porcelain insulates the live parts of the switch from the wood. These switches are mounted as shown in the figure, with the lamp sockets in four rows, where five switches are used. The number of lamps per row depends upon the desired capacity of the rheostat and the permissible length. The lamp sockets may be mounted on about 4½-in. centers.

From the figure is obtained an idea of the wiring scheme, an arrangement that permits closing switches, counting from the right-hand side. Nos. 1, 3 and 5 down and 2 and 4 up for 110-volt service; Nos. 1 and 5 down and 3 up for 220-volt use; thereby connecting two rows of lamps in series; likewise for 440-volt service, four rows of lamps would be connected in series by closing No. 1 down and No. 5 up.

A single-throw double-pole switch may be installed at the top of the board to permit the opening and closing of the rheostat without interfering with the position of the smaller switches. If portable, a handle should be mounted on the top of the board to carry the rheostat from place to place. This handle may be a hole of suitable shape cut in the board.

If the rheostat is equipped with a base so that it will stand in an upright position, both sides of the board can be used for the mounting of lamps and switches as shown in the figure. Installing lamps and switches on both sides of the board makes the rheostat twice the former capacity. If so desired, metal guards may be placed on the board to prevent the lamps from being broken. This device may be filled with any size lamps that the spacing will permit and from one to forty lamps may be cut in at will; also, four lamps can be connected in series. Therefore, it is readily seen that the individual resistance may be varied over a wide range. Where the lamps are to be connected in series, care must be taken to see that they are all of the same size.



FRONT AND SIDE VIEW OF LAMP RHEOSTAT

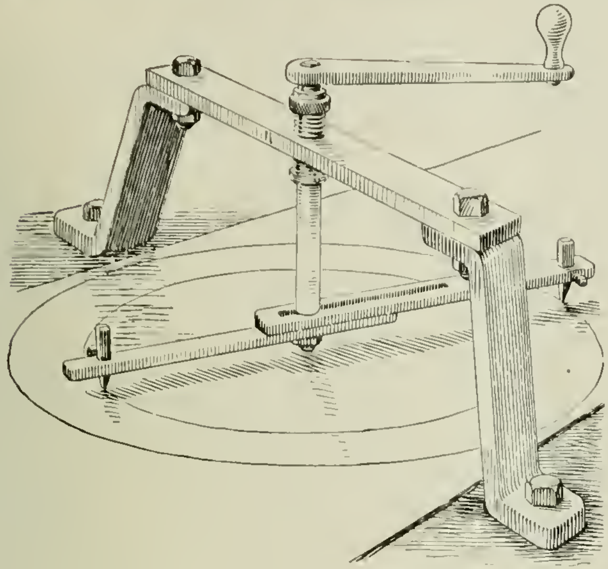
The uses to which a rheostat of the foregoing type may be put around every power house and industrial plant are almost endless. It may be used for meter checking, for testing small machines or for drying out new or damp equipment by current control, or as a heater; also for charging small storage batteries. It can be placed in the armature or shunt-field circuit of motors to vary their speed, although in the latter case care must be exercised that the field is not accidentally opened or the motor may run away and destroy itself.

It permits apparatus designed for a given voltage to be operated at a higher, by absorbing the excess voltage in the rheostat, this being accomplished by connecting a voltmeter across the terminals of the current-consuming apparatus, which is connected in series with the lamp bank. The rheostat is then manipulated until the voltage indicated by the voltmeter connected across the device is of the desired value. Another use for the rheostat is as a light cluster, and I have used it as such on several occasions to good advantage. In fact, it will be found a useful and frequently used adjunct to ary electrical equipment.

Chicago, Ill. M. A. WALKER.

An Easily Made Gasket Cutter

Having wasted considerable packing by hacking it out on the flange with a ball-peen hammer, I made a gasket cutter of the design shown in the illustration.



GASKET CUTTER MOUNTED ON A BENCH OR BOARD

The cutter bars are adjustable to suit a large range of sizes. Considering the large number of gaskets used to keep things tight, such a device is worth while.

Concord, N. H. CHARLES H. WILLEY.

Synchronoscope Needle Stuck

Paralleling a rotary converter with another machine of the same type is generally an easy job, but one morning a machine in the substation where I was working, caused considerable disturbance. The machine had been brought up to the correct speed, and we were watching the synchronoscope so as to close the oil switch at the right moment. Finally the hand revolved very slowly, indicating about synchronous speed and then suddenly swung to the zero position and stayed there. The operator waited for an instant and then closed the switch. There was a succession of flashes from the commutators of the machines, accompanied by bangs and flashes as the reverse-current relays operated and tripped out the circuit-breakers on the direct-current side. The machines began to slow down, indicating that the transmission line from the main station had opened.

The end cells of the storage battery were cut in to hold up the voltage until the machines could again be started. One of the rotaries was cut in on the starting circuit before it stopped and was brought up to speed again ready to be connected in on the alternating-current circuit as soon as the transmission line was made alive.

When the synchronizing plugs were put in again, the hand on the synchronoscope still remained at the zero position. Evidently, something was wrong with the instrument since a pair of lamps, which were also connected to indicate synchronism, were fluctuating properly; these were used as an indicator and the machines put in service. When the synchronoscope was opened, a piece of insulation was found jammed between the rotating member and the poles of the instrument, which must have happened as the needle came to zero position.

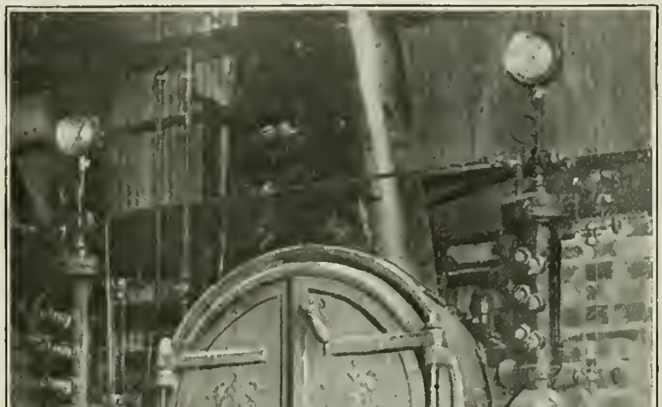
If the operator had watched the lamps as well as the indicator, he would have noticed that something was wrong and would not have closed the switch until the trouble had been investigated; which we all received strict orders to do after the experience related.

Minneapolis, Minn. E. W. MILLER.

Unusual Equipment on Small Boilers

The complaint in most small power plants is the absence of devices that render the operation less of a care. In striking contrast the photograph shows some of the equipment on a pair of 36-in. by 10-ft. return tubular boilers (normal rating 20 hp.) that have been rather overburdened.

These boilers furnish steam to the oil burners of a number of kilns and, as shown, are provided with feed-water regulators, automatic stop and check valves on the 2½-in. steam nozzles and automatic regulators for the oil burners; also damper regulators are about to be installed. One thing that catches the eye, however, is that the water columns are several sizes too large. The lower gage-cock is correctly located, but the upper one is about level with the top of the boiler.



OIL BURNER AND FEED-WATER REGULATORS

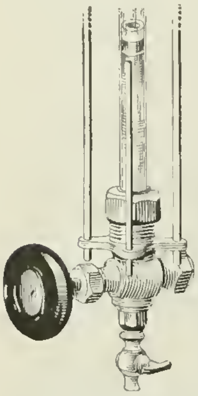
Water-Level Indicator in Gage-Glass

It is sometimes hard to see just where the water is in gage-glasses on the fronts of boilers, heaters, etc., that have become fogged and dirty. The trouble can be obviated by placing a hollow cork in the glass, as shown in the illustration, as the cork can be readily seen and being hollow and a loose fit in the glass, will not affect the level of the water. This, of course, is not a new or original "stunt," but is simply a reminder or suggestion to someone who has not thought of it. There have been numerous floats, to go into gage-glasses on the market in years past, but the cork will serve the purpose just as well and costs nothing. Giving the cork a color, red for example, that will make it more clearly visible is also advantageous in extreme cases, but is not often necessary.



CORK IN GAGE GLASS

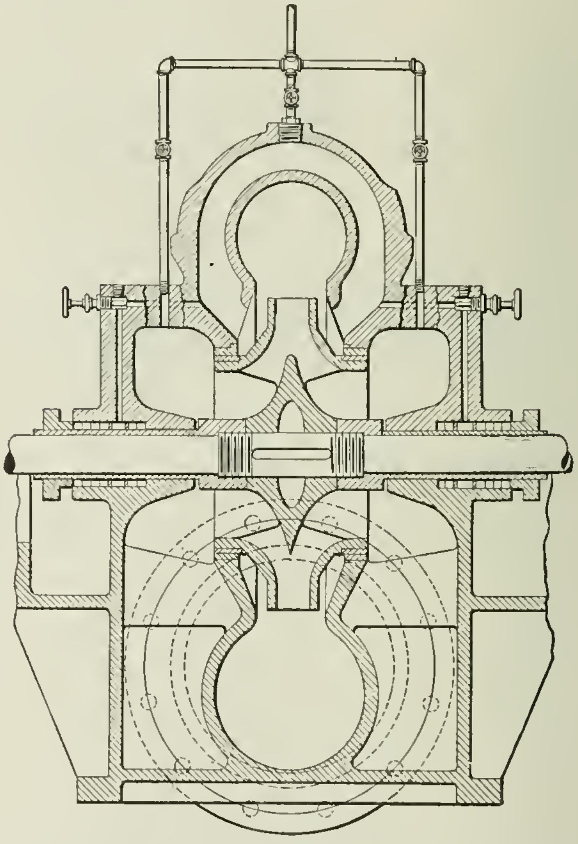
Priming Centrifugal Pumps

All high-grade centrifugal pumps are equipped with wearing rings, the duty of which is to act as packing and prevent the liquid in the pump from flowing back to the suction chamber. Therefore they must be a close running fit and have sufficient surface to prevent excessive leakage. The best pumps are equipped with double wearing rings which can be easily replaced when wear occurs. If such a pump is run without water even for a short period, there is great danger of these rings heating and scoring. Pumps have sometimes been run without water until the rings, usually made of brass, have become hot and seized and have either broken or stopped the pump; in fact, there is danger of wrecking the pump, especially a new one, when this happens. For the foregoing reasons no centrifugal pump should be run until the operator is sure that it is primed.

A centrifugal pump cannot handle air alone and for that reason is not self-priming, and air must be prevented from entering it while in operation, or its capacity will be reduced to a marked degree or the flow of water may stop entirely. The shaft is often provided with water seals or lantern glands. In operation these glands are filled with water, under some pressure, which prevents air leaking into the pump through the packing and also lubricates the packing, preventing any heating or scoring of the shaft. Some engineers have used grease successfully in these lantern glands and prefer it to water.

A centrifugal pump can be primed in a number of ways. If the water flows to the pump under a suction head, the only thing required is to open the suction valve and the vent at the top of the pump until all air is expelled, and the pump is then ready to run. If operating against a suction lift, it will be necessary to get the air out of the suction line and pump casing before it will be possible to begin pumping water. If there is a check or foot valve in the suction line, water can be run back down the discharge line against this foot valve, allowing the air to escape at the top of the pump casing. If there is no check or foot valve, the pump can be primed by exhausting the air from the pump and pipe with a water, steam or air ejector. In this case the discharge valve must be closed to prevent air coming in from the discharge line. Connect the ejector to the top of the pump casing and draw off all air; start the pump with the discharge valve closed, and when the pump is up to speed, open the discharge valve gradually and the pump will promptly go into service.

A permanent vacuum connection can be used to advantage when operating a centrifugal pump on a high suction lift. Vacuum connections should be made to all closed chambers or spaces not in open communication with the main vent opening, as shown, and when starting a pump all valves should be open; but when the pump is in operation, the valves should be open just enough so that any air coming in with or being released by the liquid will be drawn off by the vacuum. When a pump is so connected, a small amount of water is apt to be drawn over into the vacuum, but this can be controlled by the regulating valves or by running the pipe high enough above the pump to prevent any water flowing to the vacuum. If the latter method is used, it will be necessary to connect an enlarged section of the pipe in the line in order to separate the air and water and break up the air-lift action. It is possible to operate pumps provided with vacuum connections at practically full capacity on a suction lift of 27 in. of mercury with the temperature of the liquid from 70 to 80 deg. F. H. L. THOMPSON.



VACUUM CONNECTIONS FOR PRIMING CENTRIFUGAL PUMP

St. Louis, Mo.

Inquiries of General Interest

Heat Value of Coke—What is the heat value of coke? H. M.

The heat value of coke depends mainly upon the percentage of ash, which varies from 5 to 20 per cent. With theoretically perfect combustion a pound of average coke yields about 12,000 B.t.u.

Advantages of Cylinder Counterbores—What is the advantage of counterbores in the ends of steam-engine cylinders? E. L. B.

The principal advantage is to allow the piston to override the ends of the main bore and thus prevent the wear by the piston from leaving a shoulder in the main bore at each end of the stroke. Counterbores also are advantageous in requiring less length of reboring and in affording convenient means for determining the original centering of a cylinder.

Setting Boilers in Battery at Different Levels—When boilers of different sizes are set in the same battery, what advantages, if any, are to be obtained by placing them so their water lines will be at the same level? W. R. P.

The boilers will have different rates of evaporation, and to maintain proper water levels when in operation, each will require special adjustment of its feed valve. Hence no advantage is to be obtained by having a uniform level of the water lines, excepting for filling the boilers when cold by regulation of a single water-supply valve.

Soft Bearing Metal of Lead and Antimony—We wish to use a quantity of soft bearing metal and are thinking of making a mixture of 80 parts of lead to 20 parts of antimony. Would this be good proportions? F. F. B.

The high crystalline structure of antimony is likely to cause it to separate and become "rubbed out" of an alloy of lead and antimony if the proportion of antimony is higher than 17 per cent. of antimony to 83 per cent. of lead. "Carbox" metal is made in the proportions of about 15 per cent. antimony and 85 per cent. lead.

Use of Motor Below Rated Capacity—We have a 250-hp. three-phase induction motor that is used for driving a centrifugal pump requiring 170 hp. input to the motor. Is there enough loss in efficiency on account of the motor being underloaded to warrant installation of a smaller motor? A. H.

The efficiency of standard types of electric motors of 250-hp. capacity, when in good working order, ranges from 92 to 94 per cent., and the efficiency of the motor when operated at 170-hp. would be practically the same. The efficiency of the present motor is probably quite as high as might be expected of a 170-hp. motor of the same type, and a change on ground of superior efficiency would not be warranted.

Adiabatic Compression of Ammonia—What is the formula that expresses the relation of pressure to volume in adiabatic compression of ammonia? C. W.

The equation for adiabatic compression of ammonia gas is

$$p_1 = p\left(\frac{v}{v_1}\right)^{1.32}$$

where v = the volume at the initial absolute pressure p, and v_1 = the volume at the absolute pressure p_1. This formula signifies that the ratio of the volumes is to be raised to the 1.32 power and then multiplied by the initial pressure for obtaining the final pressure, or pressure obtained for an intermediate volume v_1. For compression to 0.9 of the initial volume, the equation becomes $p_1 = p\left(\frac{10}{9}\right)^{1.32} = p \times 1.149$; for 0.8, $p_1 = p \times 1.342$; for 0.7, $p_1 = p \times 1.601$; for 0.6, $p_1 = p \times 1.962$; for 0.5, $p_1 = p \times 2.496$; for 0.4, $p_1 = p \times 3.352$; for 0.3, $p_1 = p \times 4.900$; and for 0.2, $p_1 = p \times 8.368$.

Advantage of Spiral Form of Crank Arm—What benefit is derived from having a spiral form of crank arm such as sometimes used for transmitting foot power to lathes and to spindles of grinders? B. R.

The spiral form of crank arm is beneficial only when, from its flexibility, it permits of smoother conversion of reciprocating to rotary motion, or when appropriately designed, the flexibility causes the force applied to the crankpin to throw it off the dead-center, in which there may be advantage for starting off the stroke, but no less energy is required to overcome resistance that may be offered to complete revolution of the crankshaft. Various other forms of flexible mechanism have been proposed for the crank motion of reciprocating engines with the erroneous idea that they effected a saving of power, though some have been successfully employed for permitting the engine to start up from any point of stroke of the piston.

Relation of Piston Clearance to Cylinder Clearance—How is the percentage of clearance of a compressor determined, knowing the distance of the piston from the cylinder when the compressor is on a dead-center? C. W.

"Distance of the piston from the head of the cylinder" is understood to signify what is commonly termed "piston clearance," or distance the piston would have to be moved beyond the end of its stroke to place it in contact with the cylinder head. Cylinder clearance is the volume of the space in the end of the cylinder and connected passages and spaces when the valves are closed and the piston is at the end of the working stroke. The cylinder-clearance volume can be found by filling the clearance space with water and determining the volume of water required. Cylinder-clearance volume usually is expressed as a percentage of the volume displaced by one stroke of the piston: hence the percentage would be 100 × volume of cylinder clearance ÷ volume displaced by 1 working stroke of the piston.

The cylinder clearance for any assumed piston clearance will be the cylinder clearance for 0 piston clearance plus the piston displacement due to a stroke that is equal to the assumed piston clearance.

Factor of Evaporation Generating Superheated Steam—What would be the factor of evaporation under the following conditions: Steam generated at 168 lb. boiler pressure; temperature of steam, 394.5 deg. F.; feed water, 143 deg. F.? G. A. E

The formula for factor of evaporation is

$$F = \frac{H - h}{970.4}$$

where F = factor of evaporation, H = total heat of 1 lb. of the steam, h = heat of 1 lb. of the feed water, and 970.4 = the latent heat of evaporation at atmospheric pressure, or number of B.t.u. required to evaporate 1 lb. of water from 212 deg. F. into steam at atmospheric pressure.

Dry saturated steam at 168 lb. boiler pressure, or 168 + 15 = 183 lb. per sq.in. absolute, has a temperature of 374.5 deg. F. and if the temperature is 394.5 deg. F. there would be 20 deg. of superheat. According to Marks and Davis' Steam Tables of properties of superheated steam, the value of H in the formula, for the total heat of 1 lb. of the steam, would be 1209.7 B.t.u. above 32 deg. F., and as the value of h for the heat per pound of the feed water would be 143 − 32 = 111 B.t.u. above 32 deg. F., by substituting these values in the formula, it becomes $F = \frac{1209.7 - 111}{970.4}$, or factor of evaporation = 1.1322.

[Correspondents sending us inquiries should sign their communications with full names and post office addresses. This is necessary to guarantee the good faith of the communications and for the inquiries to receive attention.—Editor.]

Absorption Refrigerating Machines*

By F. C. Spangler†

Fully describes the absorption machine, high- and low-pressure, and tells how to operate and care for them. Causes of lack of capacity, making a charge of ammonia, purging the system, thawing the freezer coils, care of the ammonia-pump regulator, cleaning coils, locating slight leaks.

A SECTIONAL view of the Carbondale exhaust-steam refrigerating machine is shown in Fig. 1, and briefly described, the method of operation is as follows: The generator is filled with sufficient aqua ammonia to cover the steam coils, and the absorber with enough to submerge the water tubes. The brine pump is started and brine is circulated through the cooler coils. Then the water is turned into the machine. The inlet water enters the bottom header of the condenser and, after it passes through the condenser, enters the absorber. It circulates through the tubes of the absorber; thence through the weak-liquor cooler, and finally into the rectifier. By this arrangement the water is used four times, each stage being at a somewhat higher temperature than the preceding. Thus the water consumption of the machine is greatly economized.

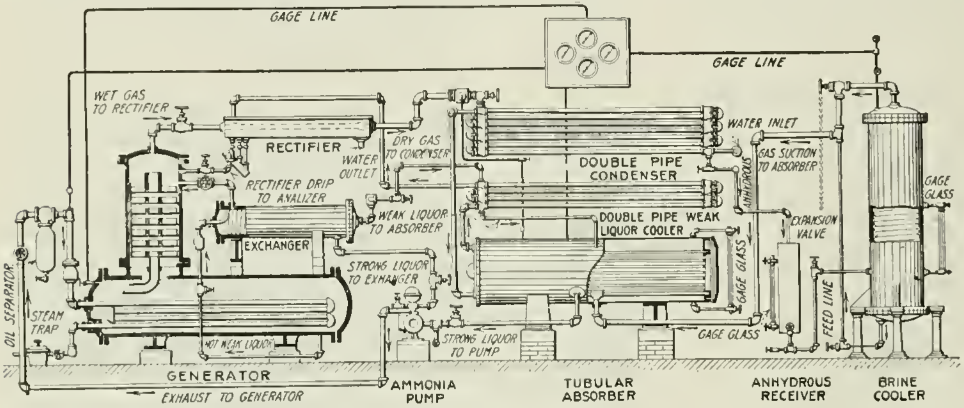


FIG. 1. TUBULAR TYPE ABSORPTION SYSTEM

Steam is now gradually turned into the generator coils until the full exhaust-steam pressure is reached. As the steam heats the ammonia in the generator, the "generator" pressure, which indicates the pressure in the generator, condenser and rectifier, will rise until it reaches a point sufficiently high to condense the ammonia gas in the condenser.

As the gas passes through the rectifier on its way to the condenser, the cool water circulating through the tubes of the rectifier chills the gas sufficiently to separate any entrained moisture that may be contained in it. The dry, or anhydrous, gas passes to the condenser, where it is condensed and falls in liquid form into the anhydrous receiver. The liquid anhydrous ammonia thus formed is then allowed to pass through the expansion valve into the brine cooler, the same as in the compression system. The expansion valve is throttled so as to keep a constant liquid level in the anhydrous receiver.

The pressure in the brine cooler is much below that of the condenser, and this drop in pressure causes the ammonia on entering the cooler to boil and absorb the heat from the brine in the coils. This changes it from liquid form on entering the cooler into a gaseous state on leaving it. The method of condensing the ammonia gas and the refrigeration that is produced in the brine cooler are identical with the compression system.

The problem now is to recover this gas. To do this, the weak ammonia liquor, which was left behind in the generator, and from which the gas has been expelled by the heat in the steam coils, is drawn from the bottom of the generator, through the exchanger, and thence through the weak liquor cooler into the absorber. Owing to the great affinity of water for ammonia gas, this weak ammonia liquor absorbs the gas in the absorber as it comes from the brine cooler, and by this means keeps down the pressure in the cooler. In turn, this weak liquor becomes enriched or strengthened by the ammonia gas and forms a strong liquor. This strong liquor is drawn from the bottom of the absorber by the ammonia pump, which discharges it into the exchanger, where it circulates around the coils that contain the weak liquor and then passes into the generator. The exchanger is simply a heat exchanger and answers the same purpose as a feed-water heater in a steam boiler plant. It heats the strong liquor on its way to the generator and cools the weak liquor.

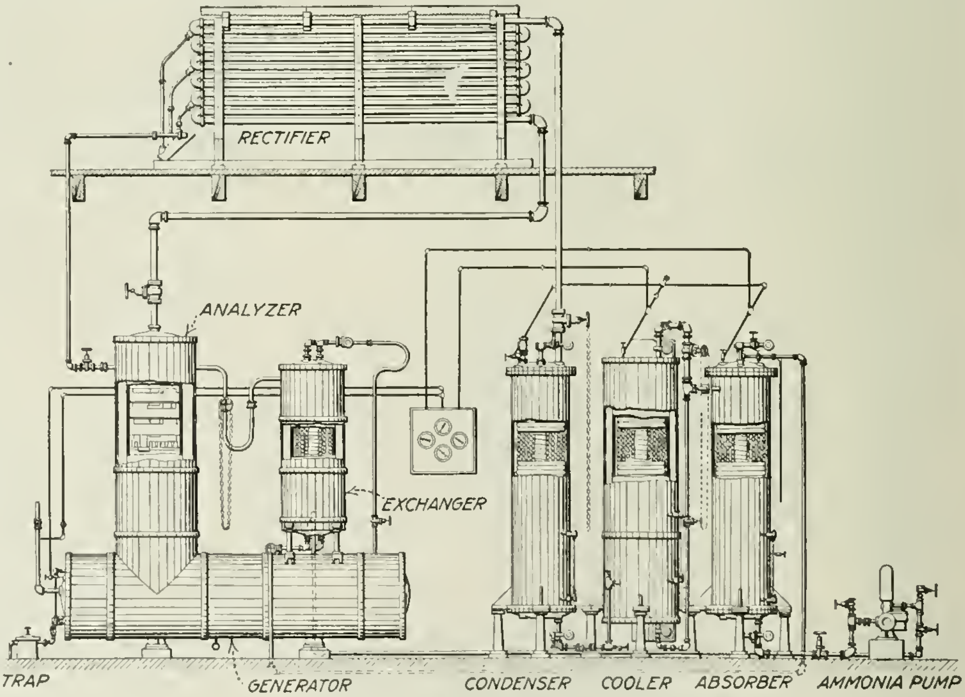

FIG. 2. SHELL TYPE ABSORPTION SYSTEM

---

*From a paper before the New York Engineers' Protective Association, November, 1917.

†Engineer, the Carbondale Machine Co., 50 Church St., New York City.

We now have the strong liquor back in the generator, ready for redistillation, and the cycle is complete.

The Carbondale Machine Co. builds three types of ice and refrigerating machines—the shell, atmospheric and tubular types. The original Carbondale construction was of the shell and coil type, shown in Fig. 2. This machine was the development of the old Pontifex design, which was brought to this country in 1884 and has been gradually improved until it has produced high efficiency. This type of machine is admirably suited for condensing water that is free from dirt and incrusting solids.

A number of these machines have been in operation for over twenty years without any coil renewals or repairs, and are giving good service today. The generator used with all three types is of the same construction and is provided with return bend coils of extra-heavy pipe. The condenser, exchanger and absorber of the shell type have cast-iron or steel shells, supplied with spiral wound coils of suitable proportion for the work contemplated.

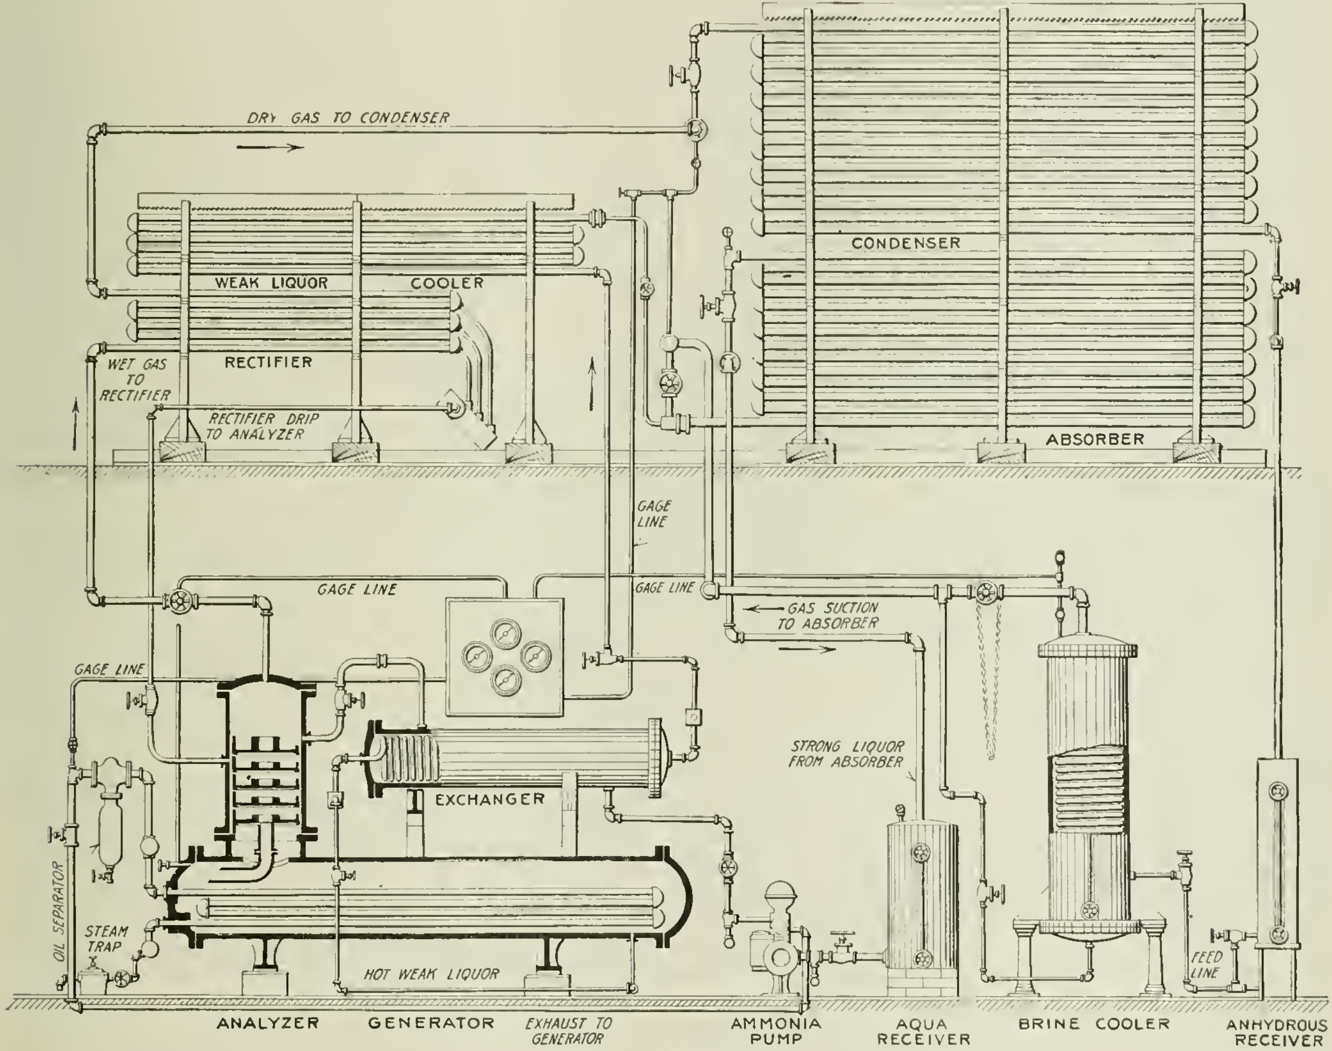

FIG. 3. ARRANGEMENT OF ATMOSPHERIC ABSORPTION SYSTEM

In case of warm or muddy water the atmospheric type of machine shown in Fig. 3 is recommended. In this machine the exchanger is of either the double pipe or shell type, the latter construction being shown. In case the water is sea water or at all corrosive, I would recommend the use of extra-heavy galvanized pipe in the rectifier, weak-liquor cooler, condenser and absorber; but in case it is of high temperature, such as comes from a water tower, full-weight ammonia pipe will answer the purpose and, if properly painted, will last for years. The rectifier is placed under the weak-liquor cooler, so that the cooling water is used by this cooler before it descends to the rectifier. The condenser is placed above the absorber, so that the water passing over it runs down over the absorber, and by this means the quantity of condensing water is economized. With the majority of atmospheric absorption machines, the condenser and absorber are located side by side and the water is used independently over each part of the apparatus, thereby increasing the consumption. The absorbers are provided with an injector arrangement.

Though a helical-coil cooler is shown, this construction can be used with expansion coils in the ice tank or with a horizontal-tubular cooler, if preferred.

The tubular type of machine, Fig. 4, is the latest development of the Carbondale construction, and consists of a generator similar in construction to the preceding types, a double-pipe rectifier, double-pipe exchanger, weak-liquor cooler and condenser and a tubular absorber. This is particularly adapted for low headroom and is easily accessible for repairs. Furthermore, containing nothing but straight pipes, it can be readily inspected and cleaned. In cases where the condensing water is corrosive, the use of galvanized tubes is recommended.

Special attention is called to the water connections. To economize, the water first enters the bottom header of the condenser, the overflow passing to the absorber. From there it passes to the weak-liquor cooler and thence to the rectifier. By this means the water is used through all four parts of the apparatus progressively and consequently the quantity of water is no greater than that required with a compression machine.

The advantages of the absorption system are: (1) It takes very little steam at 30 lb. per hour per ton refrigeration effect; (2) if exhaust steam or waste heat is available it takes no live steam except that required to run the small ammonia pump; (3) it has no heavy moving parts and cannot be materially damaged by carelessness; (4) it has no oil to clog and insulate the pipes; (5) it does not require heavy foundations, can be placed on the top floor of a building and makes no noise or vibration; (6) it can easily and economically produce low temperatures.

Operating and General Information

To start the machine, assuming that the machine has a normal charge, proceed as follows: (1) Start water circulating through machine; (2) start brine pump, making sure that the brine is circulating through cooler; (3) turn steam gradually on the generator (this steam should never be entirely shut off); (4) open the gas line between the cooler and the absorber; (5) open the weak liquor valve setting it as in usual running; (6) start the ammonia pump; (7) when the generator pressure is raised to about that usually carried, slowly open the valve between the rectifier and condenser; (8) open the expansion valve and set it. The machine now is in regular operation.

To stop machine: (1) Shut off steam on the generator, leaving a little turned on; (2) shut the expansion valve; (3) shut down the ammonia pump; (4) close the weak liquor valve; (5) close the cooler and absorber gas line valve; (6) close the valve between the rectifier and condenser; (7) shut down brine pump; (8) shut off water supply.

The causes of lack of capacity are: (1) Insufficient water supply; (2) insufficient brine supply; (3) insufficient ammonia charge; (4) air or foul gas in the machine; (5) dirty condenser, absorber and rectifier coils; (6) cooler in need of purging.

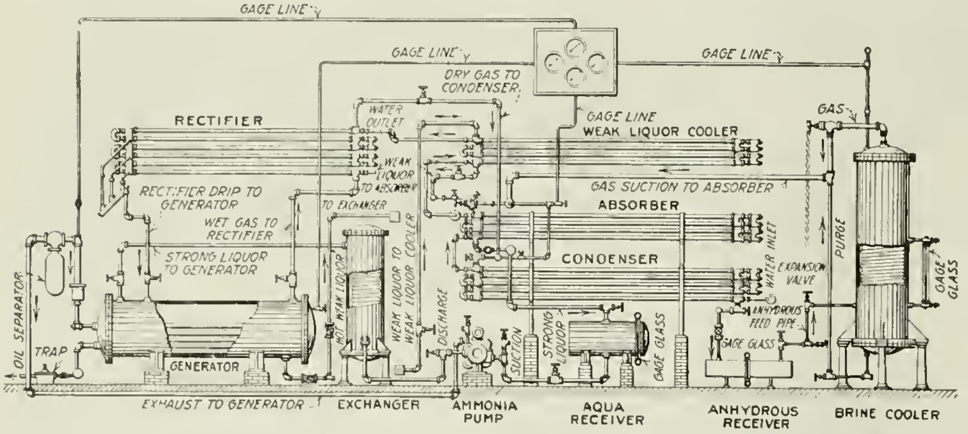

FIG. 4. DOUBLE-PIPE TYPE ABSORPTION REFRIGERATING MACHINE

Steam pressures: In case of the exhaust machine the steam pressure is usually in the neighborhood of three pounds, and does not vary. In case of the standard machine the steam pressure should be regulated according to the water temperature. Ordinarily, the steam pressure should never be in excess of one-third of the generator pressure. For example, with 150-lb. generator pressure, 50-lb. pressure on the generator is the maximum. If the machine is properly charged to do full capacity, a higher steam pressure will tend to dissociate the ammonia gas. Make sure that the generator steam coils are clear of condensation. An air-cock is provided on the bottom header for the purpose of relieving air from the coils and also indicating whether any condensation backs up in the coils. At times traps do not work properly, and it is always well to keep this air-cock open slightly to indicate any accumulation of condensation. When the machine is shut down, except for a long period, a little steam should always be allowed to enter the generator, so as to keep the shell warm.

Ammonia charge: With the machine in regular operation, and a normal charge, the following will be the conditions as indicated by the gage-cocks on the various shells. The generator will have 1 to 2 in. of liquor covering the coils. The absorber will have 1 in. of liquor covering the tubes or, if a shell type or atmospheric machine, it will have about 6 in. of liquor in the shell or receiver. The condenser will have 4 to 6 in. of anhydrous in sight, and the brine cooler will have enough anhydrous in it to frost over both gage-cocks and show a flush of soapy fluid in the glass when the cocks are opened. The gas line should be slightly frosted back to the absorber. This, however, should never frost sufficiently to show frost on the purge line.

Water supply to machine should be as regular as possible and a branch should be taken off the main at a point where other connections would not interfere with the flow to the machine.

Purging the cooler may have to be done as often as once a week, and then again not for two or three months. A cooler needs purging under the following conditions: (1) If both gage-cocks are frosted, as with normal charge; (2) if the cooler pressure is only a little, if any, in excess of the brine temperature; (3) if, on opening the cooler gage, the liquor looks watery and not soapy, then the indication is that some aqua has worked over into the cooler and that the cooler needs purging.

To purge the cooler, close the expansion and gas-outlet valve and open the purge valve leading out of the bottom of the cooler. This will drain all the liquor out of the cooler into the absorber. The pressure will rise in the cooler at first, but after fifteen minutes, will gradually fall. During the purging the pump should be run slowly and the liquor be allowed to accumulate in the absorber, which will prevent the pump from losing its suction. When the cooler has been well drained out, open the expansion valve for about thirty seconds. This will force the remaining liquor out of the cooler. After this is done two or three times and when the cooler pressure drops back to zero, the cooler has been completely purged. The machine can then be started, care being taken not to open the expansion valve too wide at the start.

The brine should preferably be made of chloride of calcium rather than from ordinary salt; it is more expensive than the latter, but does not have any corrosive action upon either pipes or valves and does not deposit solids in the coils. The gravity of the brine should occasionally be tested with the hydrometer. Brine of a specific gravity of 1.165 is safe at 6 deg. F. above zero; that of 1.200 does not freeze until it gets about 14 deg. F. below zero. If the brine is weak, there is liability of the cooler coils freezing, which would be indicated by a sudden stoppage of the brine pump. In such event immediately close the gas valve and open the expansion valve wide for at least five minutes. This should sufficiently heat the brine to thaw it and permit the pump to start.

To thaw freezer cooler, close the gas line from the cooler to the absorber and open the expansion valve wide and warm gas from the condenser will thaw out coils. Never allow the brine pump to stop when the cooler is in operation, as this is one of the causes of freezing.

When running at full capacity, the ammonia pump should circulate about ⅝ gal. of liquor to the ton of refrigeration. If a steam pump does not run steadily, but with a jerk, it is probable that there is some difficulty with the valves. These are of hard rubber or steel and should be inspected occasionally. If they become pitted in the crossbars of the valve seats, it is best to replace them with new valves. Pump rods should be kept smooth and true; any difficulty experienced in properly packing the pump end can usually be traced directly to the fact that the rod has become worn, tapering from the middle to the ends, which has a tendency to burst the stuffing-box by the wedge-like action of the rod. A properly packed box requires only a very light pressure of the gland and follower on the packing to prevent leakage. A small quantity of oil is to be used occasionally to lubricate the rod. If it is found that the pump is air-bound or gas-bound, it can be relieved by closing the suction and discharge valves and emptying the pump into a bucket of water through the pumping-out valve at the discharge of the pump. The suction valve should then be slowly opened and the pump allowed to fill with ammonia.

A regulator is provided on all modern steam ammonia pumps. It is connected top and bottom with the absorber, the liquid level line of the regulator being placed on a line with the liquid level desired in the absorber. It is of the ball-float type, the rise and fall of the ball operating the steam-inlet valve to the pump. In case the regulator does not work properly, it may be due to a stoppage in the lines to absorber or the collapse of the float. The float is of a special spun-steel type and should be purchased of the manufacturer. The regulator connections are provided with the valves on inlet and outlet, which should be closed in case it is desired to examine the float.

To get good results it is important to keep condenser, absorber and rectifier coils clean. They should be cleaned at least twice a year or oftener if possible.

Helical coils can be cleaned by blowing air and water through each coil or using some good coil compound. Tubular "coils" can be cleaned by using an ordinary tube scraper and brush. After the tubes are thoroughly cleaned it is well to coat them with noncorrosive solution, which is especially prepared for this purpose.

When the charge of ammonia is too weak, the process of distillation will not be uniform and continuous, and difficulty will be experienced in maintaining a reserve of anhydrous ammonia in the receiver, and an increased steam pressure will be required on the generator to distill over the ammonia. When this is the case, the ammonia charge must be strengthened. It should always be remembered that a weak charge entails a loss in the capacity of the machine, and that more fuel and more condensing will be required to do the work.

When starting the machine, some trouble will be experienced for a few days on account of the pressure of air in various parts. The same is true when at times the machine is recharged with aqua ammonia, which holds a considerable amount of air in solution. The air is gradually driven off from the aqua ammonia during the process of distillation and finds its way through the machine. A hose should be attached to the air valves on the absorber and receiver and dipped into a bucket of clean, cold water. If the gas coming from the hose is at once absorbed by the water with a sharp rattling noise, and no bubbles rise to the surface, and the water turns slightly bluish, all the air is out; if, however, bubbles continue to rise there is still air in the machine. When there are indications of a large amount of air in the machine it is best to shut down and blow out the air in one operation. At other times it is sufficient to slightly open the air-cocks and carefully watch for air and ammonia.

The presence of air in the machine is generally indicated by an excessive and misleading pressure in the generator and by the inability of the absorber to properly and promptly absorb the gas. It thus affects both the economy and the capacity of the machine.

With proper care and attention and by a systematic inspection of all joints, cocks and valves at convenient times, no ammonia leaks should occur; but in case of any, however small, they should be stopped at the first opportunity: these leaks are usually of anhydrous ammonia gas, and loss of ammonia rapidly diminishes the capacity and efficiency of the machine.

When the sense of smell is not sufficient to definitely locate a leak, the same can be found by holding a glass rod, moistened with muriatic acid, at or near the place of the suspected leak. A bluish-white cloud forms at the leak and immediately discloses its location. The same results can be obtained by holding burning sulphur near the leak.

Qualifications of Employees in Russian Refrigerating Industries

At a meeting of the Council of the Russian Refrigerating Committee of the Association Internationale du Froid the following resolutions, here given in part, were adopted, according to the association's bulletin.

The committee for the propaganda of knowledge on artificial refrigeration adopted the following classification concerning conditions with which employees in different sections of these industries shall comply:

Machine Section—Besides being experienced as regards the running of steam engines and dynamos, the machinist and his assistants must be perfectly familiar with the construction and operation of refrigerating machines, not only as regards the machine itself, but all its parts (condenser, coils, manometers, recording instruments, thermometers, etc.), as well as the starting of a machine and its supervision during operation. They shall have sufficient rudimentary knowledge on this subject to enable them to draw up plans, replace bolts, clamps, etc., and understand a technical description of a machine.

Cold-Storage Warehouse—The first and second inspectors shall have a good conception of cold-store construction, the operation of various refrigerating systems and their different organs and recording instruments for temperature and humidity and understand thermometer and hygrometer indications. They shall have charge of the supervision of rooms, doors and ventilating appliances and are expected to be able to distinguish the different grades of goods stored in the cold-storage plant; they shall also be familiar with the various packing systems and know the proper storage temperature for different kinds of perishables.

Icehouses—Workmen making a specialty of ice making will be employed in this branch of the business. An accounting system especially adapted for icehouses will be used.

Railway Icing Stations—Employees shall possess enough instruction on this subject to understand the rational construction and operation of icehouses and factories, ice making, ice loading into refrigerator cars, etc.

Specialists in Refrigeration (Technics and Engineering)—The general direction or management of a cold store shall be confided exclusively to a refrigerating engineer or a specialist in refrigeration. As regards the construction of a cold store, it shall be intrusted only to a refrigerating engineer.

In order to manage a cold-storage warehouse, a technical engineer must have received special instruction as regards artificial refrigeration, from both a theoretical and a practical standpoint and especially as regards the management of refrigerating machines; he shall further be familiar with the requirements of all parts of a cold store.

For agriculturists wishing to make a specialty of artificial refrigeration, a thorough knowledge of all branches of this subject is required, especially as regards the storage and transport of different kinds of perishables; inspection of all parts of the plant at regular intervals shall be organized in order to obtain the best results from the standpoints of temperature, hygrometry, etc.

Every specialist in refrigeration shall be perfectly familiar with the commercial part of this industry.

A list, appended, gives the names of schools, institutions and courses which applicants may attend in order to fit themselves for service in the refrigerating industry.

Price-Fixing and Coal Quality

Ever since coal prices were fixed by the Fuel Administration, long before the coal shortage became acute, there have been complaints of the poor quality of the coal delivered, and since the shortage these complaints have been getting more strenuous. A big coal man was asked the reason back of this recently, and he answered: "Well, for instance, we have two coal properties. One produces an unusually good quality of coal, of high heating value, with very little slag or sulphur. Before they fixed prices we commanded about forty cents a ton above run-of-mine prices for this coal, which we sold, on tests of its heating value, to public-service corporations and other institutions which were willing to pay extra for quality. Our other mine produced a much inferior grade of coal, which, however, was easier to mine. But the Fuel Administration, in fixing prices, said in effect, 'Coal is coal,' and fixed the same price for both mines. What's the answer? Naturally we are tempted to concentrate our surplus producing power on the poorer mine. Probably there are plenty of other coal men in exactly the same situation."—*The New York Times.*

Engineers in Government Service

Engineering Council, through its American Engineering Service Committee, has during the past few months supplied to various Government departments and bureaus in response to their requests, several thousand names of engineers from which men were to be selected to fill a great variety of positions in uniformed and civilian service for Army and Navy and other branches of the Government's activities in connection with the war, as well as for indirect service for manufacturers and contractors engaged upon Government war work.

To meet these demands the American Engineering Service Committee has assembled in its offices in the Engineering Societies Building, New York, extensive lists and much detailed information concerning engineers in all branches of the profession throughout the length and breadth of the land. It will readily be appreciated that if these lists are to be maintained in the most useful condition to the Government and to Engineering Council, the committee should receive promptly information concerning each engineer who has gone into any kind of Government service, direct or indirect, so that a record may be made on his cards in the committee's office.

Engineers reading these lines, to whom this request applies, are urged to send at once their names, present addresses and occupations in the Government service, with brief statement as to whether or not they are available for other service, to American Engineering Service Committee, Room 901, 29 West 39th St., New York. Other readers are asked to bring this request to the attention of such engineers or to send information directly to the committee.

Engineering Council is an organization of national engineering and other national technical societies of America of approximately forty thousand members, each member society having duly elected representatives therein, created to provide for the proper consideration of subjects of general interest to engineers and the public and for united action upon matters of common concern to engineers in all branches of the profession.

New York N. A. S. E. Offers Aid to Fuel Administrator

The following is the copy of a letter addressed to the New York State Fuel Administrator by the Combined Associations of Manhattan, Bronx and Queens National Association of Stationary Engineers:

Mr. A. H. Wiggin,
State Fuel Administrator.

Dear Sir: As the Government has for some time been considering ways and means to promote the economical consumption of fuel wherever and whenever used for the generation of heat, light and power, the National Association of Stationary Engineers, recognizing its responsibilities and duties in the present fuel crisis, hereby tenders its services to the various fuel-conservation commissions to coöperate in any capacity as their judgment may dictate.

We are anxious to demonstrate a true and patriotic spirit of coöperation to our Government in its efforts to bring our fighting forces up to the highest standard of efficiency.

We note that you have appointed a committee to report back to you on ways and means whereby the consumption of fuel may be reduced. If this is so, may we not suggest that men be represented on this committee who are actually in touch with the fuel-burning situation at all times, men who have been trained through the hard knocks of experience in fuel burning from the ground up, men who have come from the fireroom to the actual charge of the operation of the largest steam, electrical and refrigeration plants in the country?

This organization represents eleven subordinate locals in Greater New York, who are affiliated with nearly 25,000 operating engineers in the country.

Conservation of fuel does not only mean the proper burning of a combustible or the reduction of power consumption. It also means the proper application of steam through the various appliances and apparatus that are auxiliary to every power plant. In many plants changes could be made that would result in considerable saving of fuel if the necessary changes in equipment were made as suggested by the chief operating engineer.

May we further suggest that if your time permits, a personal interview be granted to a committee representing this organization, where the various phases of the question could be discussed.

Yours very truly,
D. Larkin,
President.

Discharging Warm Water in Stream

Where warm or hot water or steam is discharged into a stream in the winter time, when ice has formed on the surface and is being used by skaters, the owner of the plant is legally bound to take all reasonable precautions to guard against drowning of persons skating and exercising due care for their own safety. This should be done by erecting barriers where the ice is rendered unsafe, or by other suitable warning of danger that may not be appreciated by persons on the ice.

This statement of the law is supported by the recent decision of the Michigan Supreme Court handed down in the case of Parsons vs. E. I. du Pont de Nemours Powder Co., 164 Northwestern Reporter, 413. In this case, the court upholds liability of defendant for drowning of a boy who skated upon ice which had been rendered insecure by warm water discharged into a stream from defendant's plant, in the absence of proof showing that the boy was guilty of contributory negligence. It is decided that unless such proof be made, it must be presumed that the boy used due care for his own safety.

Personal Mention

Most men have limitations as to the quantity, quality and variety of work they can conduct with credit. Not so with J. C. McCabe, head of the Department of Safety Engineering, Detroit, Mich. The city fathers have already given him twelve distinct duties, and there are rumors of more to follow. In fact, when there is a choice bit of engineering work to do, testing or what not, requiring originality and unusual ability, an appropriation is made and McCabe is the man to do the work. The present activities of the department are as follows: 1, boiler inspection; 2, licensing of steam engineers; 3, inspection of ice-making and cooling plants; 4, inspection of elevators for construction, freight or passenger service; 5, analysis of gas; 6, use, handling, storage and sale of inflammable liquids and their products; 7, smoke inspection; 8, plumbing inspection (pending); 9, inspection of air tanks; 10, use of acetylene and calcium carbide; 11, testing of inflammable liquids and such other duties as the common council shall assign; 12, purchasing and handling coal for city departments and, in the recent shortage, diversion of city coal for industrial use.

A New Fuel—"Carbocoal"

Announcement is made of the invention of a commercial process for converting bituminous coal into a fuel called "Carbocoal," the equivalent of anthracite. A feature of the process is that by it there is recovered valuable byproducts from the coal that in present practice are wasted. The Smith process, as it is termed, takes the raw coal and separates the oils from the carbon and in turn presses the carbon into convenient shape for use.

This fuel is said to contain only 1½ to 4 per cent. of volatile matter and consists mainly of fixed carbon; in combustion it is smokeless, ignites with comparative ease, burns freely and under all draft conditions, is dustless, clear and uniform in size and quality. It is said to be suitable for use in marine and stationary boilers, for domestic use, kilns and gas producers. This fuel is to be put on the market by the International Coal Products Corporation. No address is given.

To keep polished iron or steel from rusting, mix five parts of fat oil varnish with four parts of spirits of turpentine. Apply with a sponge.

New Publications

DIRECTIONS FOR SAMPLING COAL FOR SHIPMENT OR DELIVERY—

By George F. Pope. Technical Paper 133, Department of the Interior, Bureau of Mines.

This is another one of the many publications of the Bureau of Mines on sampling coal. It deals with the time of sampling, the collection of gross samples, the size of samples, storage of gross samples, sampling from wagonloads, carload sampling, ship or barge sampling, and with the preparation of the gross sample; that is, crushing, halving and quartering. For the power-plant man this paper is probably the most useful of all that the Bureau has published on this subject. It may be had free by addressing the Director of the Bureau, Washington, D. C.

HYDRO-ELECTRIC POWER STATIONS

By Erie A. Lof and David B. Rushmore, Published by John Wiley & Sons, Inc., New York, 1917. Cloth; 6 x 9 in.; 822 pages; 408 illustrations; 66 tables. Price $6.

Water-power developments have become so closely allied with electrical engineering that it is practically impossible to give due consideration to the former without considering the latter; or, as the authors have pointed out in the preface of this book, "The work of planning, building, operating a hydro-electric power development requires a full understanding of the economic factors which enter into the problem and a thorough knowledge of both the hydraulic- and electrical-engineering sides of the subject." It is with these elements in mind that the authors have prepared this work. The book is divided into 11 chapters and 3 appendixes. Chapter 1 is a general introduction and gives data on the history of water power and electrical developments, available and developed water powers in the United States, primary power and its uses, power from inland waterways, etc. Chapter 2 deals with properties of water, rainfall, disposal of rainfall, stream flow, energy of flowing water and convenient equivalents. Chapter 3 considers the different kinds of water-power developments. Chapter 4 treats of dams, flashboards, fishways, intakes, etc Chapter 5 is on water conductors, water-hammer and surge tanks, gates and valves Chapter 6 deals with storage reservoirs. Chapter 7 takes up the problem of power-house design, embracing buildings, arrangement of apparatus, transportation and erection, starting up, general precaution, drying-out equipment, etc. Chapter 8 deals with the various types of turbines and their characteristics; governors, their operation and methods of control; pressure regulators or relief valves, water-flow meters, water-stage registers. Chapter 9 takes up the subject of electrical equipment. This chapter is very comprehensive, covering 373 pages, and gives consideration to practically every piece of electrical equipment entering into a hydro-electric power plant. Chapter 10 is also very comprehensive, occupying 100 pages and embraces the economical aspects of water-power development, such as preliminary considerations, general guide for the compilation of water-power reports and the securing of field data. This particular section is illustrated with different forms used for obtaining the foregoing data. Another very important section of this chapter is that on costs of hydro-electric power plants. This latter section gives cost data on 17 different hydro-electric power stations, varying in size from 600- to 200,000-kw. capacity. Chapter 11 gives consideration to the problem of organization and operation. Appendix 1 gives a reference to the descriptions of hydro-electric power systems in North America that have been published in the engineering publications of the United States and Canada; Appendix 2 is a table giving principal data on transmission systems operating at 70,000 volts and above; Appendix 3, standard testing code for hydraulic turbines.

In this book an endeavor has been made to describe the most recent engineering practice, and a considerable amount of information that has not heretofore been available is included. The authors, for many years being connected with one of the largest power-plant equipment manufacturing companies in the world, have had an excellent opportunity to collect valuable information over a wide range of experience The book is not a mathematical treatise, although formulas are given where necessary, but is a practical presentation in readable language of the problems that must be solved in connection with the construction, management and operation of hydro-electric power stations. Although written for the engineer and engineering students, a great deal of the material is presented in such a way that it can be easily understood by the practical power-plant operator, and should be well received by all those who have to do with hydro-electric power plants.

COLLAPSE OF SHORT THIN TUBES

Bulletin No. 99 of the University of Illinois Engineering Experiment Station contains the results of a series of experiments on the collapse of short thin tubes, made by Prof. A. P. Carman of the department of physics. The purpose of these tests was to find an equation by the application of which the pressure required to collapse a tube can be calculated when the dimensions of the tube and the elastic properties of the material are known. The bulletin gives a brief summary of earlier experiments on collapsing pressure, such as those of Fairbairn, Stewart and others, together with the formulas developed by these investigators. Then follow the description of the testing apparatus used by Professor Carman, the graphical and tabulated results of his experiments, and his conclusions. The data as given represent the results of the collapse of about 150 tubes. The majority of these were cold-drawn steel tubes from 1 to 3 in. in diameter. The remainder were of brass, aluminum, glass and hard rubber. The number of experiments on the last two materials, however, was too small to justify much generalization. The glass tubes, on collapsing, were reduced to a fine powder. The metal tubes collapsed in two, three, or four lobes, depending on the length. Copies of this bulletin may be obtained gratis by addressing the Engineering Experiment Station, Urbana, Ill.

DETERMINATION OF MOISTURE IN COKE

Technical Paper No 148, of the Bureau of Mines, Department of the Interior, deals with The Determination of Moisture in Coke, and is written by A. C. Fieldner and W. A. Selvig. The following is from the summary of the bulletin:

1. Investigation shows that the influence of temperature, time, humidity of drying atmosphere, and fineness of sample on the determination of moisture in coke may be varied over a considerable range without affecting the result appreciably.
2. Oven temperatures ranging from 105 to 200 deg. C. produced a maximum variation in moisture of not exceeding 0.3 per cent.
3. Coke can be dried to "constant weight" without any gain in weight taking place.
4. The circulation of air dried by sulphuric acid, through the oven atmosphere, as specified for coal analysis, is unnecessary, there being no measurable difference of results between circulating perfectly dry air through the oven and using in the oven the natural circulation of air from the room.
5. Moisture can be determined quickly with adequate accuracy of 0.5 per cent. by simply heating to constant weight a large sample of lump coke, in any convenient oven or on a stove, hot plate or steam coil at a temperature of 100 to 200 deg. C

Because of its simplicity and flexibility, this method may be used advantageously at points when coke shipments are sampled

Personals

S. D. Levings has resigned as Eastern representative of the automobile equipment department of the Westinghouse Electric and Manufacturing Co.

Engineering Affairs

The Association of Iron and Steel Electrical Engineers announces the following meetings: Cleveland District Section, Feb. 23, at Hotel Statler, at which B. W. Gibson, of the Carnegie Steel Co. will deliver a paper on "Generation, Distribution and Consumption of Power." The Philadelphia Section on Mar. 1, at the Majestic Hotel; John S. Rowan, of the Rowan Controller Co., Baltimore, Md., will present an illustrated paper on "Standardized Mill Table Controllers." A joint technical session, A. I. E. E. and Cleveland District Section, A. I. & S. E. E. will be held on the evening of Mar. 8, of which complete announcement is to be made later. The Pittsburgh Section's regular meeting will be held on Mar. 16 at the Hotel Chatham.

The Association of Ohio Technical Societies was organized at a conference of the engineering societies of the state held at Columbus, Jan. 29, with Clyde T. Morris, professor of civil engineering, of Ohio State University as president, and C. E. Drayer, of Cleveland, as secretary. The societies included in the association embrace every local society and local section of the national societies, twelve in number, as follows: Cleveland Association of Members of the A. S. C. E.; Cleveland Enginering Society; Cleveland Section, American Institute of Electrical Engineers; Columbus Chapter, American Institute of Architects; Engineers' Club of Cincinnati; Engineers' Club of Columbus; Engineer's Club of Dayton; Engineers' Club of Youngstown; Northwestern Ohio Surveyors' Association; Ohio Engineering Society; Ohio Society of Mechanical, Steam and Electrical Engineers; Toledo Society of Engineers.

Miscellaneous News

A Boiler Exploded on the lease of the Ohio Co. in Lawrence Co., Ill., on Jan. 29, instantly killing one of the oil workers and probably fatally injuring another. The cause of the explosion is not known.

Business Items

Fred F. Woolley, president, and John T. Sibley, chief engineer of the Hammel Oil Burning Equipment Co., Inc., of Providence, R. I., are now covering the southern power plant field from the Carolinas to Cuba and along the Gulf of Mexico to New Orleans. They are receiving numerous large orders and report that fuel oil burning in this territory will be active. Their temporary headquarters for this district is at Tampa, Fla.

The Westinghouse Electric and Manufacturing Co's. automobile equipment department has removed its manufacturing operations to the company's Newark works, Plane and Orange Sts., Newark, N. J. At this works the company has for many years been manufacturing small motors and instruments of accuracy and precision. At the same time the general sales office of this department will be moved to 110 West 42d. St., New York City, where the Eastern District Sales Office will also be located.

Trade Catalogs

Industrial Heating Apparatus. Westinghouse Electric and Manufacturing Co., East Pittsburgh Penn. Catalog 8-E. Pp. 32; 8 x 11 in.; illustrated. Describes the many different types of industrial heaters built by this company and their application.

The Yarnall-Waring Co., Chestnut Hill, Philadelphia, Penn., has issued two new bulletins illustrating and describing Simplex "Seatless" Blow-Off Valve and Simplex Pipe-Joint Clamp, also a pamphlet listing some of the users of Simplex blow-off valves and containing some sample reports and photographs of installations.

Bakelite Micarta-D Gears and Pinions. Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn. Booklet 1579-A. Pp. 12; 8 x 11 in.; illustrated. Gives technical information regarding this type of gear, such as methods of attaching to the driving shaft, that have proved suitable for these gears, tables of pitch, teeth and other gear data, formulas for horsepower rating, amount of power that can be transmitted through a press fit and for calculating other variables in gear practice.

The Moloch Stoker Co.'s Type H catalog. The Moloch Stoker Co., Continental and Commercial National Bank Building, Chicago. Pp. 30; 8½ x 11 in.; illustrated. This catalog is quite unusual in character, in that it presents the subject in a most common-sense way. Beginning with a paragraph entitled "The Economy of Mechanical Firing" and proceeding in a logical and natural manner to a clear, although nontechnical description of the apparatus featured. The text matter proceeds in a logical manner to a well-developed conclusion in which the advantages of the Moloch stoker are summarized. The catalog is well illustrated throughout with assembled and detail views of the various parts and mechanism, as well as numerous typical installations.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 14. 1918	One Year Ago	Feb. 14. 1918	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Feb. 14. 1918	One Year Ago	Feb. 14. 1918	One Year Ago
Clearfields....	....	$3.00	....	$4.25—5.00
Cambrias and Somersets...	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.69. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 14, 1918	One Year Ago	Feb. 14, 1918	One Year Ago
Pea	$5.05	$1.00	$5.80	$7.25—7.50
Buckwheat ..	4.30—5.00	2.75	5.50—5.80	6.25—6.50
Barley	3.25—3.50	1.95	4.00—4.25	3.50—3.75
Rice	3.75—3.95	2.20	4.50—4.80	4.50—5.00
Boiler	3.50—3.75	220	....	3.25—3.50

Bituminous smithing coal, $4.50—5.25 f.o.b.

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)................	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide		
	Feb. 14, 1918	One Year Ago	Feb. 14, 1918	One Year Ago	Independent One Year Ago
Buckwheat ..	$3.15–3.75	$2.50	$3.75	$3.40	$4.15
Rice	2.65–3.65	2.10	3.65	3.00	3.35
Boiler	2.45–2.85	1.95	3.55	3.15	....

PROPOSED CONSTRUCTION

Ark., El Dorado—The Arkansas Light and Power Co. plans to build an 18 mile transmission line from here to Junction City. J. L. Longino, Arkadelphia, Ch. Engr.

Fla., St. Petersburg—The St. Petersburg Lighting Co. plans to increase the capacity of its lighting plant. Estimated cost, $40,000.

Ga., Albany—The Albany Power and Manufacturing Co. is in the market for a 185 lb. hand fired 600 hp. water tube boiler. E. S. Killebrew, Supt.

Ga., Jeffersonville—City plans an election to vote on $15,000 bonds for the erection of an electric-lighting plant. W. Goodlee, Macon, Engr.

Ind., Monterey—The Monterey Electric Light and Power Co. is having plans prepared by C. Nielson, Engr., 154 West Randolph St., Chicago, for the erection of a 1 story, 50 x 125 ft. power house.

Ind., Williamsport—City plans to install new machinery in its plant including a 3 phase generating unit, directly connected, to replace the single phase unit now being used. B. Scott, Supt.

Kan., Colby—City voted $30,000 bonds for improvements to its electric-lighting plant. C. V. Parrott, City Clerk.

Kan., Wellsville—The Wellsville Electric Light, Power and Ice Co plans to purchase 5 or 10 kva. transformers soon. C. A. Smith, Mgf.

Mass., Palmer—The Central Massachusetts Electric Co. plans to issue $200,000 additional stock; the proceeds will be used to build additions and improvements to its plant. H. M. Parsons, Gen. Mgr.

Minn., Pine City—The Eastern Minnesota Power Co. plans to build a 10 mile transmission line and install a 500 kw. turbine in its plant. R. P. Allen, Mgr.

Mo., Oregon—City plans to build an electric transmission line from here to St. Joseph in order to secure electricity from there. M. R. Martin, Supt.

Neb., Dalton—The Village Board will receive bids until February 26 for the erection of a power plant and the installation of the necessary machinery. R. D. Salisburg, 1415 East Colfax Ave., Engr.

N. Y., Rochester—The Department of Public Works will soon receive bids for the erection of a central heating plant and will install a heating boiler and coal and ash handling machinery. Estimated cost, $75,000.

N. Y., Utica—The West Brewery is in the market for new machinery including motors, two 150 hp. boilers, belting and conveying and bottling machinery.

N. C., Rocky Mount—City is having plans prepared by J. N. Eley, Engr., Empire Bldg., Atlanta, Ga., for the erection of an electric-lighting plant. New equipment including a 300 hp. Heine type boiler, will be installed.

Ohio, Akron—The Northern Ohio Traction and Light Co., Hamilton Bldg., will soon receive bids for the erection of a power plant and meter building. Estimated cost, $100,000. F. C. Warner, 767 Hippodrome Bldg., Cleveland, Arch.

Ohio, Chardon—City voted $25,000 bonds to rebuild and improve its electric-lighting plant. New electric-generating units and an entire change of system from 133 to 60 cycle, will be installed. Noted Nov. 27.

Ohio, Cleveland—The Board of Education will receive bids until February 25 for the installation of three 350 hp. water tube boilers, stokers for same, 2 boiler feed pumps and one 150 ft. radial brick chimney, 96 in. diameter for its central heating plant.

Ohio, Wellington—The Board of Trustees of Public Affairs is in the market for flywheel, 40 x 10 in. to 14 x 6 or 6½ in. bore to weigh about 1000 lb. C. E. Gadfield, Supt.

Penn., Philadelphia—The Colver Electric Co. has petitioned the Public Service Electric Co. for authority to issue $25.000 additional stock; the proceeds will be used to build additions and improvements to its plant.

Penn., Reading—The Metropolitan Edison Co. plans to issue $97.500 in bonds; the proceeds will be used to build additions and improvements to its plant.

Tex., Dallas—The Dallas Light and Power Co. plans to build an electric transmission line from here to Norwood. R. C. Brooks, Supt.

Va., Richmond—The Richmond, Fredericksburg and Potomac R.R. is having plans prepared for the erection of an addition to its engine house. Estimated cost, $20,000. W. D. Duke, Gen. Supt.

Wash., Seattle—The Union Lake Co. plans to build a third addition to its power plant. Estimated cost, $600,000. K. J. D. Ross, Supt.

Ont., Stratford—The G. McLagan Furniture Co. is in the market for a horizontal steam boiler, 16 ft. long and 6 ft. in diameter

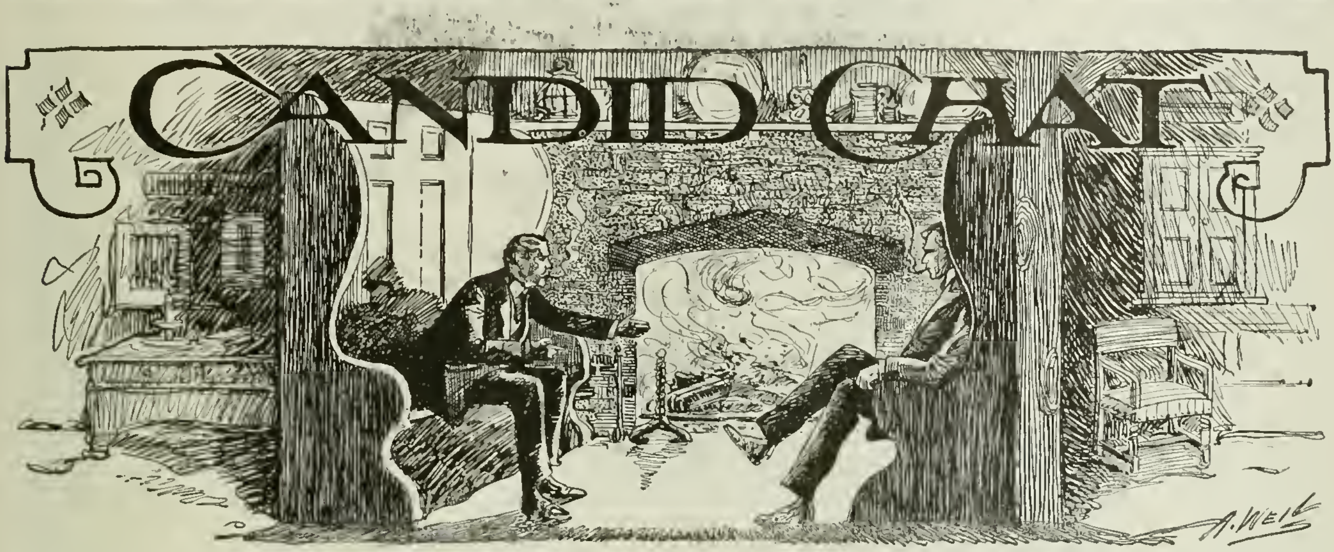
Que., Warwick—The Warwick Overall Co. is in the market for a 20 hp. electric motor.

---

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

POWER

Vol. 47 NEW YORK, FEBRUARY 26, 1918 No. 9



The Engineer and His Position

THE era of efficiency having arrived, what has the operating engineer done to prepare himself to meet it?

Operating a power plant, whether it is in a hotel, mill, office building or railway station, is not what it was some years ago.

Power-plant engineering has advanced rapidly in recent years, and for the engineer to keep pace with it requires continuous study. If he does not read and become acquainted with the new appliances and methods that are being introduced, he will slide into a rut and hold his position only until the owner becomes convinced that he can find someone who can operate the plant efficiently.

DOES your plant operate efficiently? If not, are you to blame, or is it the boss' fault? If you're guilty, how long do you think the owner is going to keep you when there are others competent to handle your job and glad of the chance?

When a manufacturer finds that competitors sell the same goods for less than he can, he investigates the cause. If an expert reports that one great contributing cause is poor plant management, who "gets it in the neck"?

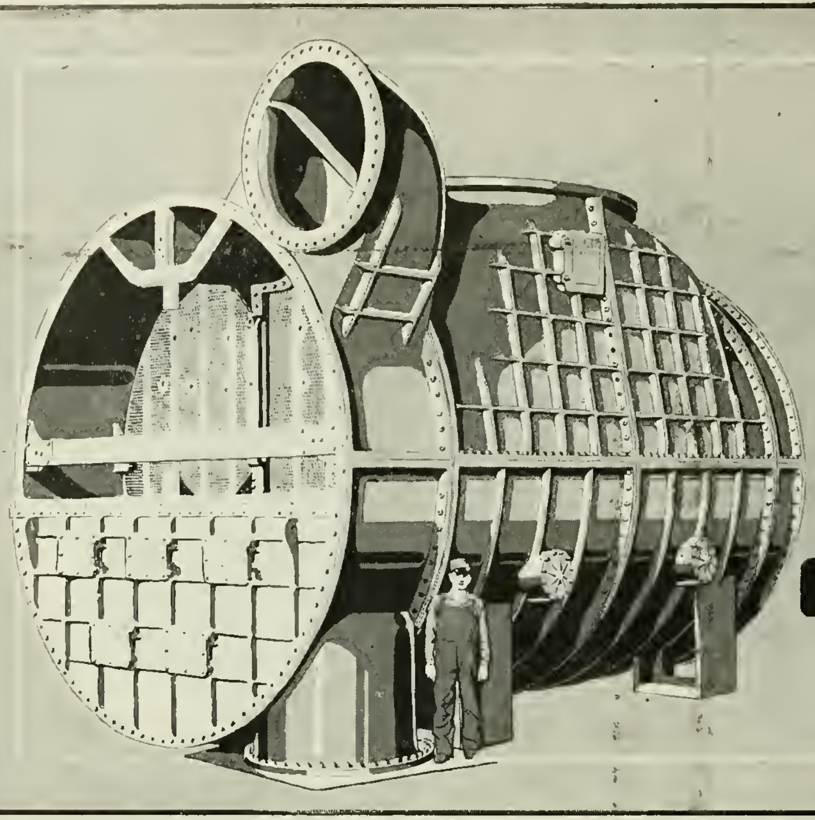
Sometimes it is difficult to operate efficiently because you have not the equipment for doing so, but no matter how bad the machinery or equipment may be, you can make an attempt at keeping a record sheet or log. When this is done, it is convincing proof that you are onto the job.

Your vest pocket is not the place for a log or record sheet. Keep it where it will create a healthy rivalry between the men, and also get their co-operation. That is what makes for success.

UNITY in the department should be the watchword. It is a pleasure to see the competition between the men, as one watch is trying to beat the record of the other, and you, checking up each day, are devising some way to make a better record than the previous one.

After you have started to keep up-to-date records, possibly you find you do not have the instruments or apparatus necessary to keep them accurately, but if you will take the matter up with the manager and a good reason is shown him why you should have them, he will, no doubt, after seeing what you are striving for and knowing that it is going to save money, acquiesce and give you all the assistance desired. It is then that you are headed right and becoming the kind of man the management wants you to be, the kind you want to be and the kind your fellows like to call acquaintance and friend. You are then headed for a better job.

Contributed by David Larkin, Chief Engineer, Fifth Avenue Building, New York City.



A FIFTY-THOUSAND SQ. FT. CONDENSER

A surface condenser having 50,000 sq.ft. of cooling surface, serves a 30,000-kw. turbine. The condenser is in a pit 74 ft. deep, and the exhaust pipe between the turbine and the condenser is 13 ft. diameter and 40 ft. long. It is provided with a special design of expansion joint. The circulating pump is below the low-level stage of the river.

WITH the increase in the capacity of turbine-generator units for power-plant service the sizes of the condensers that serve them have also increased, and improvements and refinements in design have been made. Some of the notable condensers that have been developed and put in service during the last year or two are, for instance, the 50,000-sq.ft. surface condenser of the New York Edison Co., and also one of the Chicago Commonwealth Edison Co., that serves 30,000 kw. generators. Another large condenser, a Leblanc, serves a 45,000-kw. turbine of the Narragansett Electric Light Co., Providence, R. I. It is designed to handle 18,000,000 lb. of circulating water, condensing approximately 500,000 lb. of steam per hour, an equivalent of 36 lb. of circulating water per pound of steam. The largest condenser so far built is one for the Detroit Edison Co., which has 70,000 sq.ft. of cooling surface.

Another installation of large surface condensers, of which there will be six, the largest yet built of the Leblanc surface type, is to be located at the bottom of a pit 74 feet deep, Fig. 2. At present there are two 50,000-sq.ft. surface condensers that serve the two 30,000-kw. turbines installed in the present structure of the Windsor power plant of the American Gas and Electric Co. (See headpiece.)

Both condensers are of the straight downflow type, with the tubes so spaced that steam lanes are provided so that all parts of the cooling surface can do their proportionate share of the condensing and thus insure a minimum pressure drop between the steam inlet and the air-pump connection. Each condenser contains muntz-metal tubes, of 18 B.w.g. and 18 ft. long. The condensers are 18 ft. inside diameter and 25 ft. long. A portion of the tubes in the upper portion of the condenser, aggregating about 2400 sq.ft., are used as a primary feed-water heater through which the condensate is pumped before going to the two open feed-water heaters. The primary heater brings the temperature of the condensate up very near to that of the incoming steam. Each condenser is set below the turbine which it serves, as shown in Fig. 2. As the turbine must be above the highest point which the river reaches and the condenser must be low enough to avoid lifting the water at low stages, the 13-ft. diameter exhaust pipe is 40 ft. in length.

Expansion of the pipe and the vertical expansion of the condenser are taken care of by a mercury expansion joint, Fig. 1, designed especially for and constituting one of the really novel features of the installation. It is 13 ft. in diameter and consists mainly of a fairly close-fitting cast-iron sleeve so formed as to permit a manometric column of mercury to make a seal to prevent air leakage and at the same time permit of a free motion of the upper and the lower halves of the joints relative to each other. The upper part of the joint is built so that if for any reason the mercury arrangement part of it should fail, an ordinary slip joint with soft packing could be used. This is not installed, inasmuch as the mercury joint operates very well, but it is readily seen that in case the mercury joint should fail, the part of the joint around the gland and packing could be immediately turned into an ordinary slip joint with soft packing in the part that is marked "Rope for Packing."

The dotted portion marked "Expansion Joint Clamping Block" is not used with the joint in service. This is simply an arrangement whereby the two portions of the joint can be firmly fastened together for shipment. That portion is removed after the joint is in place.

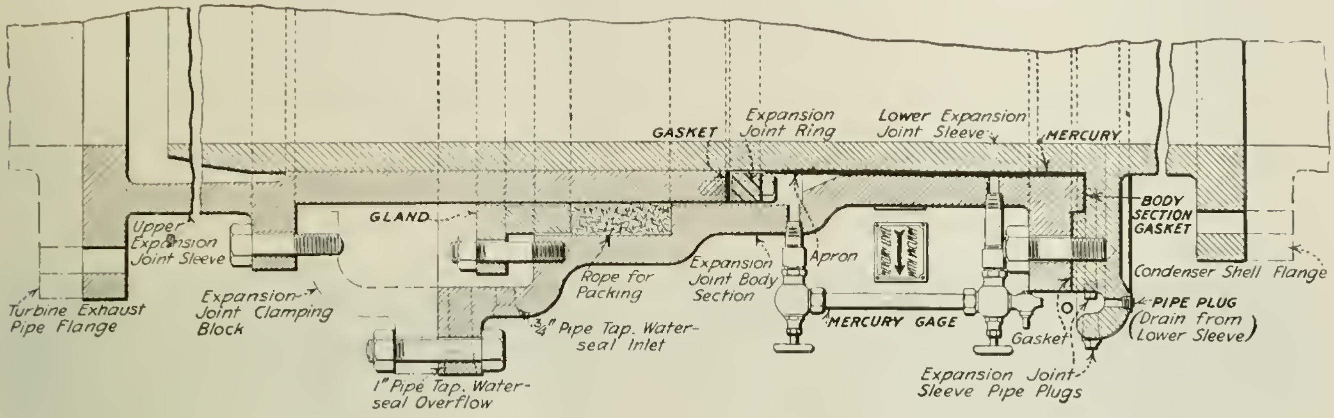


FIG. 1. DETAILS OF THE 13-FT. DIAMETER MERCURY EXPANSION JOINT

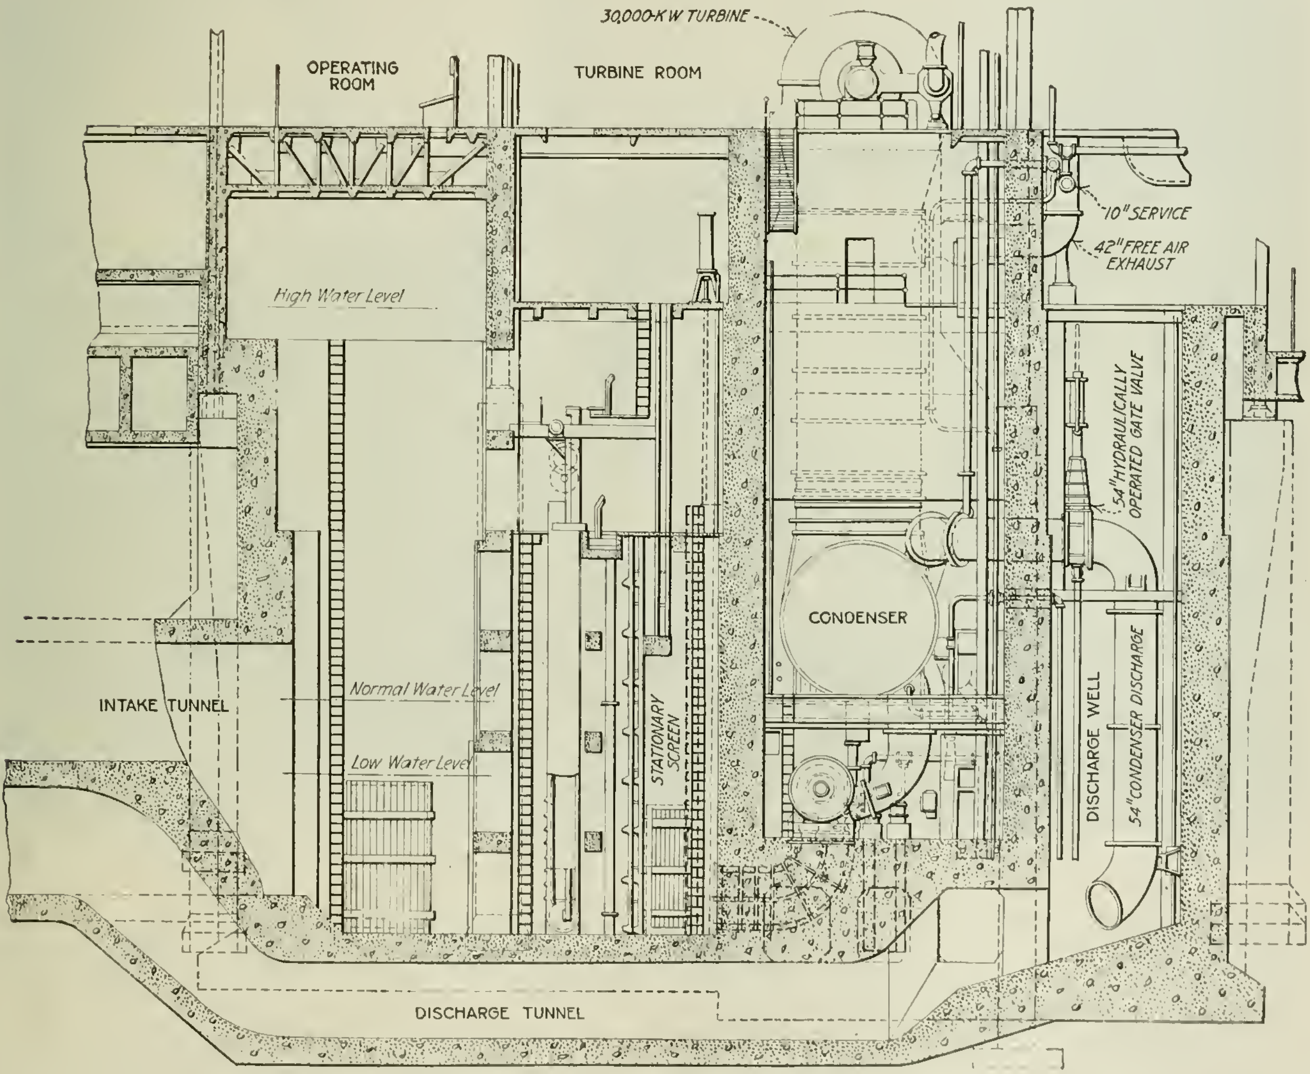

FIG. 2. ELEVATION OF THE INTAKE WELL AND CONDENSER PIT

It was decided that this type of joint was necessary because the great vertical distance between the condensers and the turbines entailed an extraordinarily great expansion in case the apparatus should be much changed in temperature. The mercury expansion joint can take up an indefinite amount of expansion, whereas there would be a danger that a copper joint, with the great distortions necessary, would ultimately fail.

With each condenser is furnished a horizontal motor-driven circulating pump having a capacity of 50,000 gal. per min. There are also two motor-driven Leblanc rotary hydraulic-type air pumps and two motor-driven hotwell pumps. Water from these pumps is supplied from two steel tanks in the basement of the power plant, and it is discharged back into the tanks. Makeup water is taken from the discharge of the circulating pump. The centrifugal hotwell pumps are driven by 550-volt three-phase 60-cycle squirrel-cage induction motors that are provided with special insulation to withstand the damp atmosphere of the pit.

At this writing no plant tests have been made on the turbines, but assuming 12 lb. of steam per kilowatt-hour, each condenser will take care of 360,000 lb. of steam at rating or 7.2 lb. per sq.ft. of cooling surface and 8.3 gal. of circulating water per pound of steam condensed at rating. Per kilowatt of generator rating the condenser contains 1.67 sq.ft. of cooling surface.

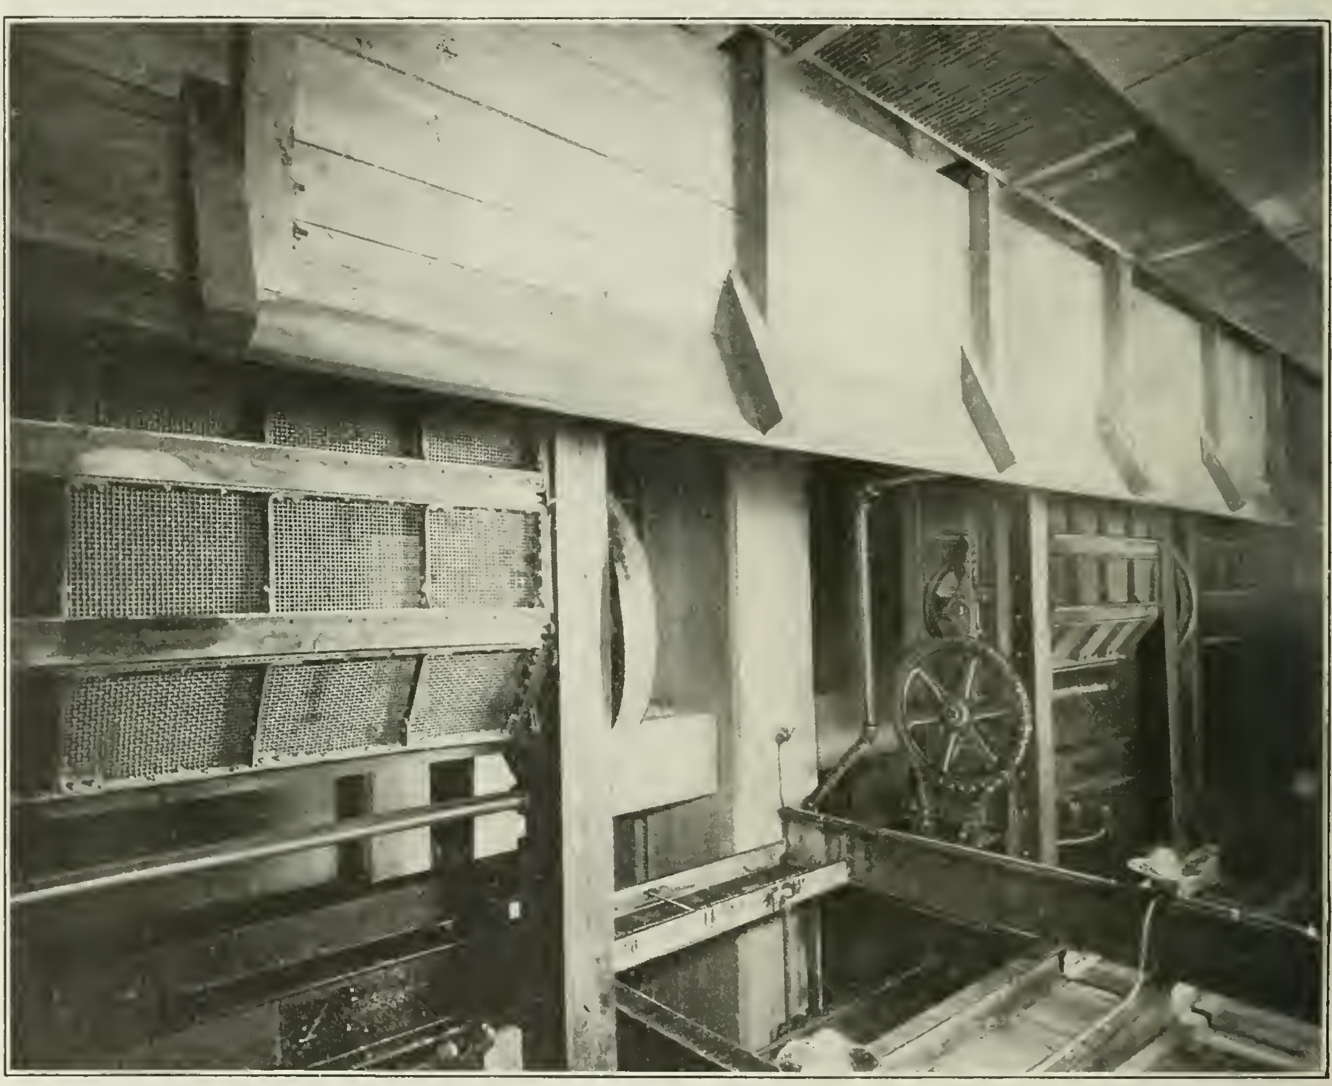

FIG. 3 VERTICAL REVOLVING SCREENS AT THE INTAKE TUNNEL

The opening into the condenser pit is centrally between the steam ends of the two turbines, the foundations of which are formed by the walls of the condenser pit. The Ohio River at Windsor has a rise of 50 ft. from extreme-low to extreme-high water, which necessitated the construction of a condenser pit with the bottom 74 ft. below the turbine-room floor. The basement floor is just above the high-water mark, and the main floor is 18 ft. higher. With the condenser-pit floor 74 ft. below the turbines, it was possible to place the center line of the circulating pumps at the same elevation with the extreme low level of the river, thus reducing the cost of pumping the circulating water to a minimum.

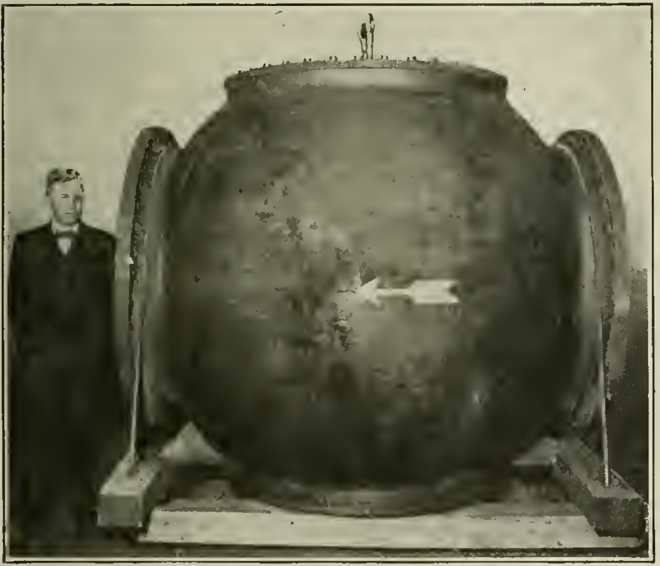
Steel cross members support the condenser at a height of about 15 ft. above the floor of the condenser pit, which provides space for the circulating air and hotwell pumps. The concrete intake and discharge tunnels for the condensing water are built to take care of the proposed ultimate capacity of 200,000 kw. Water coming from the Ohio River through the intake tunnel goes to an intake crib inside the turbine room at the condenser well of Nos. 1 and 2 condensers. From this crib the water passes successively through bar-iron grills, traveling screens and stationary screens to a rear chamber of the crib. The 84-in. diameter cast-iron suction pipe of the circulating pumps drops to this chamber. Water from the condensers discharges from a side outlet on the upper side at one end through a 54-in. cast-iron pipe into a discharge well that connects to the discharge tunnel, and is returned to the river below the intake.

When the remaining four condensers are installed, they will receive circulating water through tunnels running from the crib to the intakes of their circulating pumps. Each circulating-pump intake pipe is provided with an extra-heavy sluice gate, Fig. 3, operated by a hydraulic cylinder for controlling the flow of water to the pumps. The general station arrangement permits the screens in the crib to be handled by the 110-ton turbine-room crane, which is provided with a 15-ton auxiliary hoist. The traveling screens are mounted in a vertical position and are so arranged that they can be raised or lowered.

Figures regarding the construction of the tunnels and condenser pit are of interest. The intake and the discharge tunnels from the river to the intake in the station building required approximately 30,000 cu.yd. of excavation, 5300 cu.yd. of concrete and 270 tons of reinforcing. The condensing pit, which is 25 ft. 6 in. wide, 91 ft. long inside and 74 ft. deep, required approximately 32,000 cu.yd. of excavation, 13,500 cu.yd. of concrete placed and 514 tons of reinforcing steel, as well as 315 tons of structural steel used in the construction.

A Forty-Eight-Inch Relief Valve

There has recently been built one of the largest relief valves ever manufactured, for the Conners Creek plant of the Detroit Edison Co. It is a 48-in. horizontal exhaust relief valve, and is hydraulically operated. It will serve as a safety relief for the condenser on a new turbine unit. The complete valve weighs 14,000 lb. and measures 7 ft. 5 in. from face to face of the flanges. The cast-iron valve disk is 48 in. in diameter and has a metal ring face which seats on a brass ring. It is water-sealed and is double-cushioned with brass-lined dashpots above and below the disk. The valve stem is 3½ in. in diameter. The illustration gives an idea of the relative size of the valve; it was built by the G. M. Davis Regulator Co., Chicago, Ill.



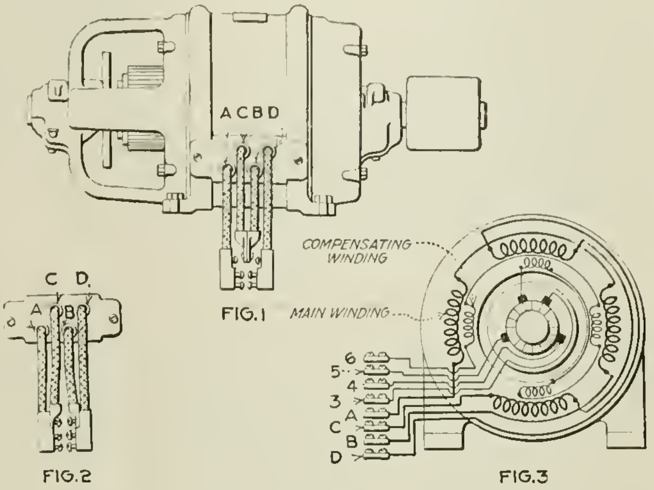
A 48-IN. EXHAUST RELIEF VALVE

Variable-Speed Motor Used in Constant-Speed Service

By E. C. Parham

Repulsion-induction motors of the constant-speed type have four leads coming from the stator winding, as in Fig. 1. If the supply voltage is 220, the two short leads are connected together as in the figure, thereby connecting the two sections of the stator winding in series. If the supply voltage is 110, then each short lead is connected to a long lead, as in Fig. 2. This connects the two sections of stator winding in parallel.

In some types of repulsion-induction motors they are equipped with a set of energy brushes and a set of compensating brushes on the commutator. Inside of the motor frame the two energy brushes are connected together and the two compensating brushes are connected to the compensating field winding. Where such a motor is to be used on variable-speed duty, the energy and compensating circuits are opened and the ends appear at the outside of the motor as two more pairs of leads that are to be connected to the controller by means of which the speed is varied by varying the amount of resistance included in the energy and compensating-field circuits. Where such a motor is to be used on constant-speed duty, no controller is required and the two energy-brush leads are connected together, also the compensating leads, the stator leads being grouped according to the voltage and connected to the starting switch.



FIGS. 1 TO 3. ARRANGEMENT OF LEADS FROM A REPULSION-INDUCTION MOTOR

Figs. 1 and 2—Constant-speed motor. Fig. 3—Variable-speed motor.

A second-hand repulsion induction motor was bought and applied to the driving of a pump through a worm and gear. The motor was complained of because it could not be started. What puzzled the local electrician was that the motor had eight leads and the starting switch had connections for only two wires coming from the motor. Investigation developed that the motor formerly had been used on variable-speed duty and it now was to be used in constant-speed service.

The leads of the energy brush-holders always are tagged 3 and 4 and those of the compensating brush-holders, 5 and 6 as in Fig. 3; and in this particular case the tags were still in place. By lifting the brushes, so that the holders would not be connected together through the armature, and testing, the energy leads 3 and 4 were identified and connected together, also the compensating leads 5 and 6 were found and joined. The stator leads were easily identified because each short lead was connected to the long lead nearest to it, showing that the motor formerly had been operated on a 110-volt circuit. As the work in hand called for 220-volt operation, the short leads were disconnected from the long ones and connected together, as in Fig. 1, and the two long leads connected to the motor side of the starting switch. On closing the switch, the motor started promptly, and it gave no further trouble.

Measuring High Pressures With Dead Weight

BY SANFORD A. MOSS

Engineer, Turbine Research Department, General Electric Co., Lynn, Mass.

Complete details are given for using the equivalent of the dead-weight pressure-gage tester for measuring pressures during tests as used in the steam-turbine department of the General Electric Co., Lynn, Mass.

EVERYONE who has had any experience with the use of Bourdon pressure gages, even of good quality, knows that they are more or less troublesome when extreme accuracy is desired. Frequently the calibrations before and after the test disagree. Even if the calibrations do agree, there is often a question as to whether the temperature effect has been properly taken care of. Most Bourdon gages are not accurate to a per cent., therefore, they are usually read to one per cent. by estimation between graduations. Accuracy of the construction probably does not warrant closer graduation than the coarse one usually given.

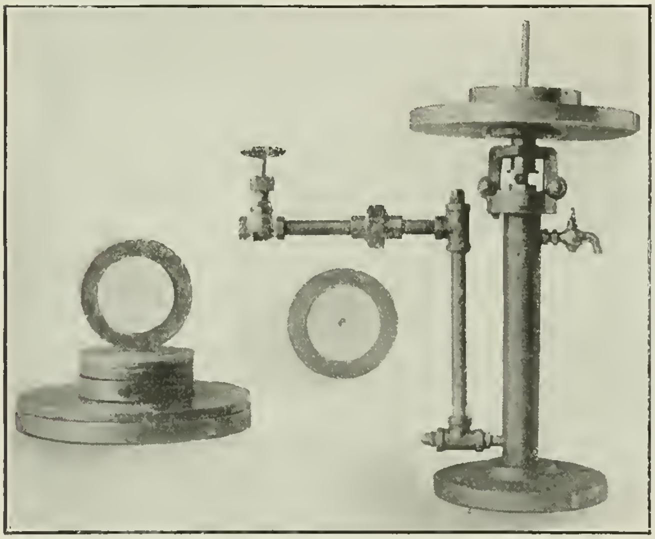


FIG. 1. DEAD-WEIGHT PRESSURE GAGE

The dead-weight pressure gage consists of an accurately bored cylinder, usually having an area of one-eighth of a square inch, with a closely fitting piston, at the top of which is a platform on which are placed weights sufficient to keep the gage floating. The instrument in this form has been in use for many years for testing pressure gages. For use in direct measurement of pressure, the addition of a stop must be made to prevent the piston from rising out of the cylinder, and an oil trap and reservoir so that there is sure to be oil in contact with the cylinder and piston. The construction can also be cheapened from that usually adopted in dead-weight testers. The platform and piston must always be spun by hand when the apparatus is in use.

The use of a dead-weight apparatus thus attached directly to the pipe where pressure is being measured, gives accuracy to within about 0.25 of one per cent. without any difficulty whatever. The dead-weight apparatus is cheaply and easily made and easily operated. Considerable experience indicates that it is satisfactory in every way. Fig. 1 shows the apparatus used in the turbine department of the General Electric Co.'s Lynn works, where there are about fifteen outfits, all in more or less regular use. This system has been in use in this department for over ten years. Fig. 2 indicates the manner of installation, operation and a machine on test. Fig. 3 gives a sectional view of the apparatus.

The apparatus is primarily adapted for testing work where the pressure is constant or nearly constant and where the exact value, whatever it may be, must be known at frequent intervals, or where an exact value must be held by hand regulation. Following are some tests in which dead-weight gages have been used.

A. Laboratory test of a steam turbine, or the like, at a given load point such as full-load, half-load, etc. Steam pressure is held by hand regulation at an exact value for which the turbine is rated. In such a case of course the boiler pressure must be somewhat higher than the rated pressure and an attendant at all times holds the pressure at the exact rated value. If the Bourdon gage were used, there would be more or less uncertainty about the pressure due to variations of the boiler pressure or governing of the turbine; the throttle valve is being opened or closed slightly at all times during the test. The Bourdon gage, for pressures that vary, gives an appreciable difference. On the contrary, with a dead-weight gage, the attendant, after ten or fifteen minutes' practice, can hold the rated pressure within 0.25 of one per cent. or less. In such a tes

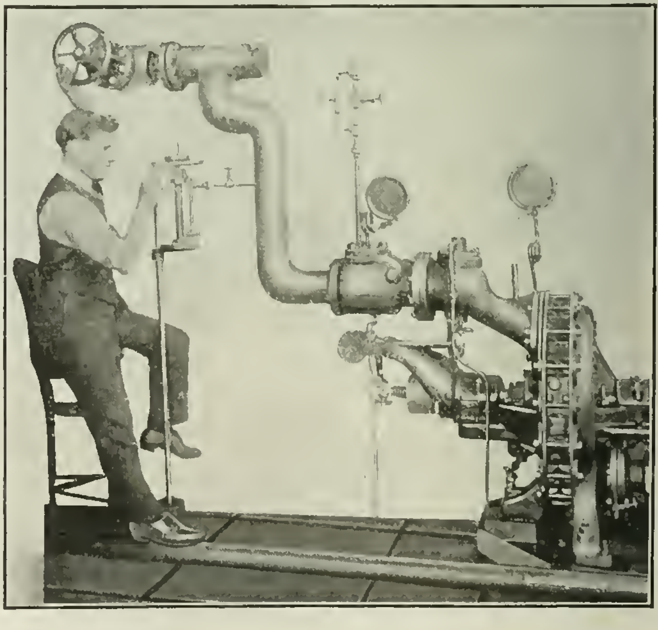

FIG. 2. DEAD-WEIGHT GAGE INSTALLED ON TURBINE

the load, which is an electric generator, is either held exactly constant by hand regulation of water rheostats or the like, or else is set at nearly desired value and allowed to drift up and down near the correct value. If the load or steam pressure varies rapidly, the dead-weight pressure gage cannot be used.

B. Calibration of steam-turbine nozzles or other work on flow of steam, or high-pressure air through orifices. Here there is a constant opening through which a fluid is discharged, and a constant pressure is to be held by hand regulation of a throttle valve just as in the preceding case. The steam is of course condensed and weighted at successive intervals. The flows during each interval should be all alike. Much greater precision is secured in this particular with a dead-weight gage than with a spring-pressure gage.

C. Test of any other type of steam or high-pressure air machinery where an exact pressure is to be held by hand regulation at all times during the test.

D. Test of a high-pressure centrifugal pump. Here a dead-weight gage can be used with great satisfaction to measure the discharge pressure. If the volume flowing is measured by means of orifices, another dead-weight gage can be used to measure the orifice pressure.

E. Test of a high-pressure air compressor. If the compressor is a reciprocating machine, there must be the usual air receiver with capacity enough to smooth out the pressure fluctuations so that the dead-weight gage will give the average value. Here also, if the air-compressor flow is being measured by means of an orifice, a dead-weight gage can be used to give orifice pressure. If the flow of the reciprocating compressor is being measured, the arrangement of the orifice must be especially attended to. There must be a large receiver, and a throttle valve between discharge pressure and orifice pressure so as to reduce the orifice pressure a very considerable amount. This throttling smooths out the flow so that the pressure is not pulsating at the orifice. As is well known, the average value of a pulsating orifice pressure does not give the average flow. If the orifice can be made large enough, it is best to reduce the orifice pressure by throttling until it is about 15 lb. per sq.in. Then the orifice dead-weight gage could be discarded altogether and a mercury column used.

In orifice tests of pumps or air compressors, as in D or E it is necessary to have two dead-weight gages or one dead-weight gage and one mercury column, since there are two distinct pressures. One of these is a discharge pressure measured in the pipe between the throttle valve and the machine and gives the pressure with which the machine is to be credited in computing its performance, efficiency, etc. The throttle valve cuts down this pressure so that any desired pressure can be had on the orifice so as to give any desired volume or amount of flow, which is computed from the orifice pressure. This orifice pressure may be measured by means of a static hole in the pipe wall with a pipe connecting to the dead-weight gage or mercury column, or an impact tube may be used in the jet discharged from the orifice as explained in the paper, "The Impact Tube," A. S. M. E. *Transactions*, December, 1916.

F. Measurement of high pressures during any experimental work such as hydraulic work, high-pressure steam work, or the like, or calibration of thermometers by means of high-pressure steam. The dead-weight gage of the construction here described has been successfully used for pressures up to 500 lb. per sq.in. without any difficulty. For very high pressures, pistons of larger diameter, as well as lever devices for balancing the piston, have been proposed. Just how far the one-eighth-inch piston with direct balancing can be used, and the magnitude of the pressure when it is necessary to resort to other devices, cannot be definitely stated.

During use of the dead-weight gage in any test such as the preceding ones, if the pressure variation is such as to require constant adjustment by an attendant, there must be provided a throttle valve at a convenient location and the gage must be piped near-by. The attendant then has one hand on the throttle valve and with the other hand spins the dead-weight gage, as in Fig. 2. He turns the throttle valve backward and forward so as to keep the gage floating between the top and bottom stops. After about ten minutes' practice anyone, even an unskilled laborer, can keep the gage floating without any difficulty whatever.

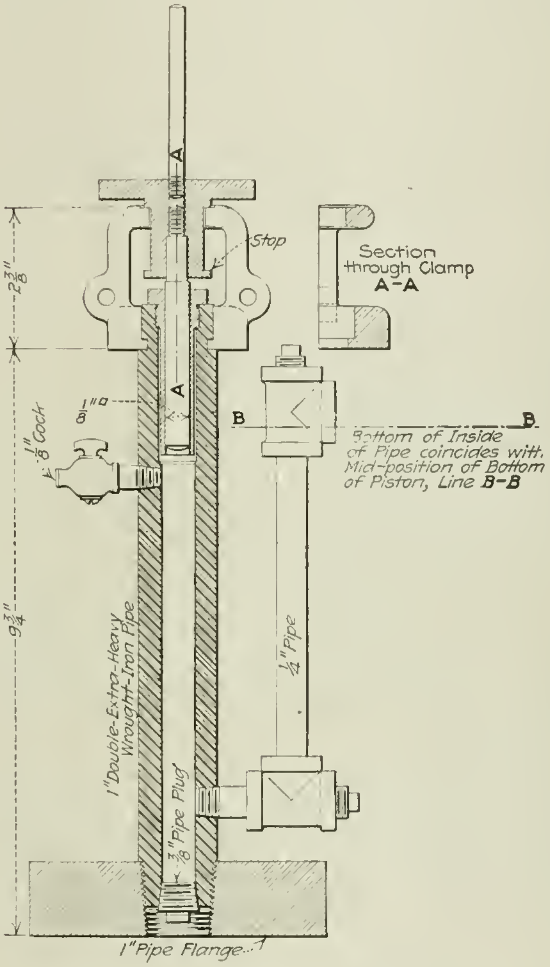

FIG. 3. SECTIONAL VIEW THROUGH DEAD-WEIGHT PRESSURE GAGE

In some tests the pressure does not vary much, so that no hand regulation is required. In such cases, whenever a pressure reading is needed it must be taken by adding or subtracting one-pound weights until the gage floats. During all periods when reading of the gage is being observed, it must be spun by hand. For this reason it is an advantage to have the heavier weights thin and of large diameter rather than thick and of small diameter, so that a single spin will persist for a long period.

The valve used to regulate the pressure which is read by dead-weight gage must be adapted to that purpose. If the valve is too large, the motion is so small as to be difficult. If it is too small, the motion is too large. The easiest way of handling this matter is to have two throttle valves in the line. One of these is set at such a point as to give easy manipulation of the second one, which is thereafter the one regulated to keep the gage floating.

TABLE I. WEIGHTS TO GIVE ABSOLUTE PRESSURES FOR VARIOUS BAROMETER READINGS

Uncorrected Barometer Reading Inches of Mercury	Temperature of Mercury, Degrees F.								
	60	65	70	75	80	85	90	95	100

31.0	4.80	4.80	4.80	4.80	4.80	4.85	4.85	4.85	4.85

As seen in the figures, the dead-weight gage is connected so that there is a "U" of oil with the piston at the top of one leg and the applied pressure at the top of the other. The pipe from the latter point must be led downward to the place where the pressure is being measured, so there will be no chance of a water trap giving error. The point from which the pipe is led downward must be nearly on a level with the average position of the bottom of the piston, so as to automatically maintain the liquid level the same in the two sides of the "U."

If the gage is filled with oil at the beginning of a test, there is usually not enough oil leakage to require any refilling. The gage was originally filled by removing the stop casting and lifting the piston out of the cylinder. However, with the piping arrangement shown in the figures, removal of the stop casting and piston is avoided as follows: The two plugs in the tees at the top and bottom of the side-pipe leg are removed and the vent cock opened. After the water has run out, the bottom plug is inserted and oil added at the top opening.

In air tests, a slight oil leakage during the test gives an error of a head of oil equal to an inch or so. In steam tests the gage oil is replaced by water so that the error will only be that due to the difference between an inch or so of oil and an equal amount of water. As in all pressure measurements, the pipe connecting the dead-weight gage to the place where pressure is being measured, must be absolutely tight. This pipe is usually ¼-in. standard material. However, if there is any appreciable length of pipe, it should be made ½ inch.

Any dead-weight gage tester can be used as a dead-weight gage by arranging a stop so that the piston cannot be ejected from the cylinder. However, the gages on the market are of more expensive construction than is desirable for ordinary pressure-measuring purposes, so that home-made ones similar to that shown in Fig. 3 must be used, until some manufacturer produces a gage whose cost is considerably less than that of the present types on the market. The gage shown was made by purchasing pistons and cylinders from a manufacturer, which were made with the precision necessary for this work. A stop was fastened to the piston and holes bored in the platform so as to leave the weight the same as before. The weights were carefully made by use of a precision scale, so as to weigh within 0.1 of one per cent. of the correct amount. The pressure in pounds per square inch for each weight is of course eight times that of the weight in pounds.

In the course of comparative tests with a given machine on different days, if the same dead-weight gage pressure is held, the absolute pressure will vary. For accurate work this is avoided by use of a set of barometer weights. These vary from 4.85 to 6.05 lb. per sq.in. by 0.05 lb. and are selected according to the barometer so as to give the same absolute pressure each day, as per Table I.

The first column of the table (as well as Table II) gives the actual reading of the mercury column of the barometer without correction for mercury temperature. The headings of the other columns give various values of the temperature of the mercury column of the barometer, and the body of the table gives that one of the barometer weights which is to be added on the gage. The other weights to be used must total the desired absolute pressure minus 20; that is, the weight placed on the gage should be the desired absolute pressure in pounds per square inch, minus 20, plus weight in table.

TABLE II. INCHES OF WATER TO GIVE 15 LB. PER SQ.IN ABSOLUTE EXHAUST PRESSURE

Fifteen pounds per sq in. equals 30.35 in. of mercury; 1 in. of mercury equals 13.6 in. of water.

Change of barometer also affects the absolute exhaust pressure in comparative tests made on different days of a noncondensing steam turbine or the like. Although this point has nothing to do with dead-weight gages, a method of handling the absolute exhaust pressure will be given. This is to always hold such back pressure on the exhaust line as will give exactly 15 lb. absolute pressure. This is accomplished by putting a water U-tube on the exhaust line and throttling the exhaust until the back pressure indicated by the U-tube plus the reading of the barometer is such as to give the desired absolute pressure. Table II gives the inches of water to be held in the U-tube to secure this effect, taking into account the temperature of the barometer column.

Some Why's of the Coal Shortage

There have been many assertions as to the cause of the prevailing coal shortage in that those interested in the production, transportation, handling at the terminals and in the delivery to the coalyards claim that the trouble has been due to the failure of some other arm of the coal-handling organization. Some of the causes for the scarcity of coal are enumerated in this article.

IT HAS been asserted almost countless times that the American public do not realize that we are at war. This may have been true to a great extent prior to Jan. 16, when, by the order of Dr. Harry A. Garfield, Fuel Administrator, practically all of the industries east of the Mississippi River were closed for a period of five days and by which order, countermanded now, Mondays were to be workless until Mar. 30; but the assumption does not now apply. The five workless-days bomb was an effective awakener for the American people to the fact that war does exist. Furthermore, the average citizen knows more about the coal situation today than he ever did before the closing-down order went into effect.

SHORTAGE TRACEABLE AS FAR BACK AS JULY

That there is and has been a serious shortage of coal, both for domestic and manufacturing purposes, is without question a fact. Thousands of individuals have their belief as to the cause, and they are varied. It is evident to many that the coal shortage does not date back to the extreme cold weather of the past few weeks, but rather that it is traceable as far back as July of 1917.

Previous to this date the coal operators had reduced their rates from $5 and $6 to $3 per ton, and a few days later the Secretary of War reduced the price to $2.50 a ton for all coal sold to the Government. Those who thought they were foresighted and who were accustomed to put in winter coal during the summer months held off with the idea that a better price would obtain later on. The result was that the movement of coal during the summer months was greatly retarded because consumers delayed their buying, and the possibilities are that orders for thousands of tons of coal were cancelled. It is easy enough now to see that this was a mistake and that this coal should have been purchased and delivered before the cold weather came to delay traffic and freeze the coal in the cars, which so seriously delays the unloading. Naturally, the time lost because of the public waiting for a lower price could not be made up after the price of coal was fixed at $2 a ton, during the latter part of August, and which was later found too low and increased to $2.45.

Has price fixing saved the public money? This is a debatable question. One thing is certain—there has been a loss to the country in the extra coal produced because the price fixed by the Government is for run-of-mine coal and the added tonnage mined is largely slate and refuse. That some of the coal operators have no scruples about putting their hands in the pockets of those who cannot afford to spend an extra nickel for coal is evident when they ship trash that is being sold for fuel at a price that is high for a good grade of coal.

There was produced 642,340,134 short tons of coal in 1917. This coal in normal times should run not higher than 8 per cent. ash, but much of it is running as high as 18 per cent. at the present time and some of it as high as 35 per cent. It is safe to assume that there is at least 6 per cent. more ash included in the total coal shipped to consumers last year than in the year previous, which if true would mean that 38,540,408 tons of last year's coal output is in the form of increased ash and bone. Taking an average of 45 tons per car, this would mean that 856,453 carloads of ash is being added to the transportation difficulties of the railroads. At 60 loaded cars per train there would be required 14,274 locomotives to move this material that has no heating value.

EFFICIENCY OF FUEL DECREASED

This useless transportation of noncombustibles does not stop with the delivery of the cars at their destination. It has been determined by experiments conducted by the Bureau of Mines, that there is a decrease of approximately 1.5 per cent. in efficiency for each 1 per cent. additional ash contents to the coal, and an increase of 6 per cent. in ash content over normal conditions means that the efficiency of the coal is reduced about 9 per cent., which, plus 6 per cent. additional ash in the coal now being sent to the consumer, makes a 15 per cent. reduction in the efficiency of the fuel.

It would seem, then, that although more fuel was shipped from the mines last year than during the previous year, there is an actual decrease in the effective coal received by the consumer. This is certainly a matter that the Fuel Administration at Washington should take in hand. The writer has seen coal that looked fully 40 per cent. slate and incombustible, which is being sold to the consumer. Selling such coal at the prevailing prices makes the offense of stealing pennies from a dead man's eyes look like a virtue in comparison.

THE RAILROADS SAID TO BE AT FAULT

The tying up of 14,000 locomotives in hauling as many trains of 60 loaded cars of ash is one of the several reasons for the present fuel shortage. More than one man occupying a responsible position asserts, and with apparent justification, that the railroads are at fault in that they have failed to render the full measure of car service of which they have been capable, and some believe that this has been done deliberately to make it appear that the recent demands for higher freight rates were justifiable.

It has also been claimed that for every period of decline in coal production since the United States entered the war figures show that the railroads were rendering less car service than in the corresponding weeks or months of the preceding year, and furthermore, that there has been misuse and nonuse of available cars. That is, if the empty cars had been shipped back to the mines as soon as they were unloaded instead of being held on side tracks, there would have been enough cars to move all the coal required both by the manufacturers and by the public at large. The coal shortage is reported as being approximately 10 per cent. of the requirements, and it is also claimed that the railroads' performance is about 10 per cent. less than it was in 1916.

Inefficiency on the part of the roads is also charged, and this applies to the repairing of motive power, the lack of which is one of the principal causes for the freight congestion at various points of the railroad systems. The demand for locomotives is so great that only such repairs as are absolutely necessary are made, and minor repairs, such as would increase their efficiency, are left undone.

CONDITION OF EQUIPMENT BELOW NORMAL

That the railroads have neglected to maintain their equipment at normal is shown in the orders they have issued from new locomotives during the last year. The following figures regarding this feature of the railroad difficulties are of interest: A total of 3467 locomotives were ordered by the American railroads in 1913, 1262 in 1914, 1612 in 1915, 2910 in 1916 and 2704 in 1917, an average of 2391 per year during the past five years. In 1905 there were 6255 locomotives ordered for use in the United States. At least 5000 new locomotives, it is estimated, are needed each year by the railroads of the United States. Foreign orders for 1916 totaled 2983, and in 1917 there were ordered by our Allies 4938 locomotives, of which 2057 were for the use of the United States in France. The actual deliveries to our railroads were 5332 locomotives in 1913, 1251 in 1915, 2708 in 1916 and 2587 in 1917. The deliveries to foreign countries were 2861 in 1917. As the railroads of the United States have for the last three or four years ordered but a little more than half the number of locomotives required to move the tonnage consigned to them, there is little cause for speculation as to why they have fallen down in their attempt to move freight and do away with congestion that appears to block the freight yards throughout the country.

INCREASE IN CAR MILEAGE AND TONNAGE HANDLED

On the other hand, railroad statistics for 1917 show that the average car mileage per day was 27.7, as against 27.5 for 1916, and that there was 18 per cent. increase in the coal tonnage handled in 1917 over 1916. Railroad officials claim that they can deliver to terminal points only such coal as is consigned to them and that they do not control the acts of the shipper. As an example, one railroad had one day recently 600 steel cars of 50 tons capacity each, or sufficient to carry 30,000 tons of coal, distributed at the anthracite mines that it serves. When these cars were loaded, they went in all directions—not as the railroad's manager chose, but as the shippers directed.

That something is radically wrong is self-evident, and some of the trouble that has resulted in a gigantic freight jam may be due to a cause similar to that recently published in the Boston *News Bureau:*

> A. R. Whaley, former operating vice president of the New Haven, recently inspected the congestion in the Jersey terminals and was discussing it with the yardmaster, an old-time railroad man.
>
> "What is the basic trouble?" asked Whaley. "We used to handle things better."
>
> "I'll tell you," said the yardmaster. "Twenty-five years ago, when you and I started, they had wooden cars, but they had men of steel handling them. Nowadays, they've got steel cars, but there's a blamed lot of wooden men handling them."

Snow and extreme cold weather have contributed to the coal shortage by delaying rail transportation and the unloading of the frozen coal from cars into barges for water transportation.

New England, as well as New York and other Eastern cities, is a sufferer. In Boston about 90 per cent. of the 45 coalyards are bare of fuel. The railroads have been unable to increase their shipments, and but little coal has been coming in by water.

Among other things that contribute to this condition is the order that was given earlier in the season to ship coal to the Northwest, with the result that it could not be absorbed and thousands of loaded coal cars have been standing on the tracks between the mine and the West; this is one cause of car shortage. The condition is traceable back to the fixing of prices of coal and the uncertainty of getting it. Much of the trouble that New England is experiencing is due, it is believed, to the holding up of coal shipments during several weeks during the summer months and fall, in the endeavor to obtain lower rates to the tune of one dollar per ton.

New England uses approximately 25,000,000 tons of coal per year, most of which comes from the Virginia coal mines. This year there was required about 7,000,000 tons more.

Another reason why New England is out of coal is because the Government commandeered five of the thirty-five collieries that brought coal to that section and also took over seven out of forty-five tugs that were used in towing from two to four coal barges at a time. As a matter of fact, then, there has been 1,000,000 tons less of coal brought to New England by water, and on the other hand the roads have brought in about 1,000,000 tons more than usual.

The coal-mine operators claim that the coal shortage is due to lack of cars. They maintain that it is idle to talk of increasing the output of the mines until the cars are available to transport it. They claim that the coal production could be greatly increased if there were cars in which to load it. It is pointed out that on the average 200,000 coal miners are idle each day in the year because the output cannot be handled by the railroads; that there has been no falling down in the production of coal at the mines, but that the trouble is due to distribution.

Loss of coal output can be easily traced to the method of shipping, whereby coal going to one section passes coal going in the opposite direction. That is, it is a waste of mileage, locomotives and car haulage to ship coal to a consumer, say 400 miles or so from the mines, when coal could be obtained in a mine not more than 200 miles distant. This method of distribution has been carried on unchecked and has undoubtedly cost the nation thousands of dollars. Recently, S. Peabody advocated before the Senate Investigation Committee a zone system dividing the country into thirty distinct districts, and he stated that it would increase the country's output of coal by 20 per cent. Under such a system no coal would be sent out of one zone into another without a license from the Fuel Administration.

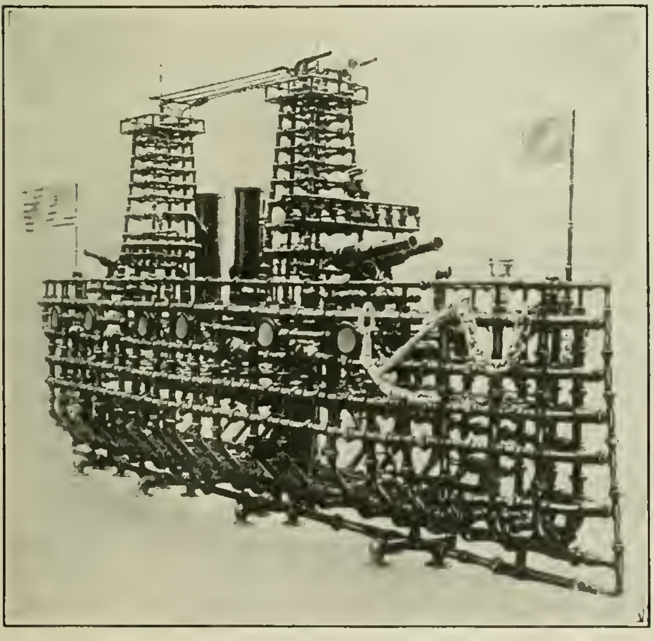
That there will be a scarcity of coal during the rest of the winter and well on into the spring is a foregone conclusion. What the situation will be after that is problematic. Conditions will doubtless change for the better to some extent, but it will be impossible to get coal in large quantities. That a repetition of present conditions shall not prevail next winter a number of changes in the handling of coal should be made.

The householders should order coal during the summer months. The coal operators should be made to sell clean coal, not adulterated with ash and bone. The unloading piers should be equipped with suitable means for thawing frozen coal in cars. The railroads should repair their locomotives and order new ones so that their motive power can handle the volume of freight that must reach the points of delivery. Empty cars should be moved to the mines as fast as they are emptied, and the fuel and railroad administrators should work together to bring such changes about.

New England should be taken care of by seeing to it that sufficient bottoms are available for transporting coal by water and thus avoid their present predicament.

Model of Superdreadnaught "New York"

The illustration gives a view of a model of the superdreadnaught "New York," made completely of Crane Co. products—fittings, valves, specialties, etc. According to the *Valve World*, the model was designed and its construction supervised by an employee of Crane Co. in the works of the company's Bridgeport division. It is now on exhibition in the Crane exhibit rooms, 23 West 44th St., New York.



MODEL MADE OF FITTINGS

The over-all dimensions of the model are: Length, 186 in.; breadth, 34 in.; molded depth, 42 in., total height from keel to topmast, 102 in. Its net weight is 3308 lb., and 6669 separate pieces were used in its construction. It is complete to the smallest detail, and the ordinary working parts of a battleship are movable. A small electric motor gives action to the propeller. The ship is electrically wired throughout, the wires running in conduit, and by the pressing of a button action may be seen everywhere—the propeller turns, the commander salutes, lights flash, guns roar, the wireless crackles, the searchlight throws a searching beam. The entire action is automatic and may be repeated indefinitely or until the pressing of another button stops it. A row of colored electric lights runs from bow to stern over the mast tops, and when in action the model makes an interesting exhibition.

Eleven Ohms the Resistance of a Circular-Mil-Foot

By T. A. Nash

The resistance of a circular-mil-foot of copper depends on the purity of the copper and on its temperature. The resistance of ordinary commercial soft-drawn copper wire at 70 deg. F. is almost exactly 10.6 ohms. However, the use of the value of 11 ohms in the formula for a two-wire circuit,

$$\text{cir. mils} = \text{amperes} \times 11 \times \text{total length of conductor in feet} \div \text{volts drop},$$

is justified. In computing wire sizes for interior-wiring circuits, it is folly to endeavor to figure too closely. The length of the circuit is probably not known within 10 per cent., the purity of the copper to be used is unknown, and finally, one must use conductors of one of the standard wire-gage sizes. Hence, it is common practice to use the 11-ohms value in practical calculations because the results obtained by using it will, on the average, be as accurate as those obtained by using 10.6 ohms, and it (11 ohms) is an easier figure to handle. Also the value 11 ohms can be remembered easily.

Inexperienced Draymen Damage Heavy Machinery

A recent purchaser of a large air compressor points out that irresponsible draying firms cost the purchaser of heavy machinery far more than is saved by patronizing inexperienced firms who will take a job "for less." The point is that serious damage can be easily done by inexperienced teamsters in delivering heavy machinery from railroad depot to plant and it may be that this damage will not be discovered until the plant is being tested in operation. In that case the blame may never be properly placed and is very likely to be charged up to the manufacturer as a defect in construction. The case in point occurred recently in a Western city. Some large-sized compressors were hauled across the town in such a position on the dray that the stress of shocks from the wheels was carried by bolts in the lining of the cylinder, which separated the water jacket from the compressor chamber, and these stresses so strained the bolts that a joint was opened and leakage resulted that caused much delay and inconvenience after the unit had been put in operation. In this instance a capable mechanical engineer saw the compressor in its strained position on the dray and at once entered a protest, predicting the possibility of the trouble which, in fact, later developed.

Mine Plant Saves Forty-Five Tons of Coal Per Day

Installation of a new boiler plant, utilization of exhaust steam by a low-pressure turbine and a change from steam and compressed air to electric drive for auxiliaries and mine pumps resulted in a reduction of fuel of from 90 to 45 tons per day. Besides, the mine capacity per day was increased 50 per cent.

ABOUT two years ago the Chicago & Carterville Coal Co. decided to improve its power plant at Mine A, at Herrin, Ill. The plant at that time consisted of eight horizontal-tubular boilers 72 in. diameter by 18 ft. long, one 250-hp. and one 350-hp. water-tube boilers, each being equipped with an independent steel stack. The equipment supplied by the boilers consisted of one 250-hp. and one 450-hp. air compressors and also one 170-kw. electric generating unit. Standard steam piping with screwed fittings was used.

All the auxiliaries around the mine, consisting of the coal washer, the centrifugal pump for the washer, the shaker engine, the engine for driving the shop, the main fan and various other small units, were steam-driven. The steam lines were run underground in many cases with no insulation. Most of the joints were leaking, and the entire plant was in a deplorable condition, being extremely wasteful in the use of steam. Under these conditions it required 90 tons of coal per day to operate the plant, nine firemen for the three shifts and three ash wheelers. No. 4 washed coal was burned under the boilers.

After a careful examination it was decided to install a new boiler plant, consisting of water-tube boilers equipped with chain-grate stokers, and a 500-kw. mixed-pressure turbine to utilize the exhaust steam from the present air compressors and fan engine. Provision was made also for using, at some future date, the steam from the main hoisting engine by the use of a regenerator. There was no need to draw on the hoisting engine for the time being, as the two compressors would furnish more than enough exhaust steam to operate the low-pressure turbine at full load.

STEAM DRIVE REPLACED BY ELECTRIC

All the steam-driven auxiliaries were to be replaced by electric-driven units with the exception of the engine driving the main fan. Distributed at various points about the mine were several pumps that had been operated by compressed air taken from the main air lines in the mine, supplying the punchers used for undercutting the coal. These pumps were extremely wasteful in the use of compressed air, and it was decided to replace them with direct-connected centrifugal pumps, and in a few cases where gathering pumps would be required of a portable type, with motor-driven reciprocating pumps.

On account of the scarcity of water for condensing purposes, it was decided to install a spray pond, the makeup water being drawn through a 4-in. line from a small pond about a quarter of a mile distant by a motor-driven pump. The plant had been operating on city water, as the water available close to the mine was too poor in quality to use in the boilers. The new arrangement provided for a vertical motor-driven submerged centrifugal pump placed at one corner of the spray pond, which delivers the water direct to the feed-water heater.

The new boiler plant consists of three 350-hp. water-tube boilers, two being new and the third a boiler from the old plant. All are provided with chain grates and are connected to a 7 x 210-ft. concrete stack, the stack and breeching being arranged for the installation of an additional boiler at some future time.

PUNCHERS USED TO UNDERCUT COAL

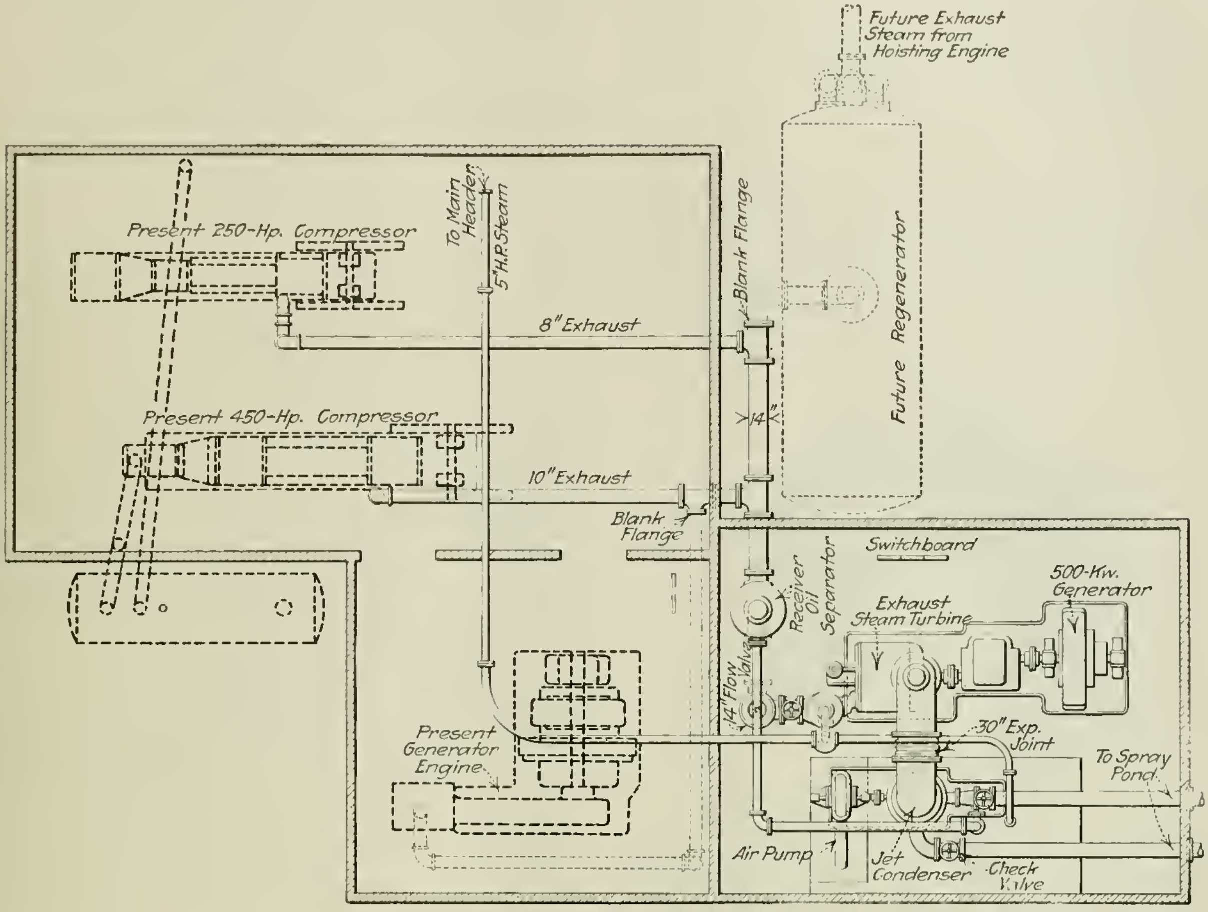
As previously stated, the present method of undercutting coal is by the use of punchers driven by air furnished by the two compressors now supplying exhaust steam to the low-pressure turbine. It is the intention, however, at some future time to do the undercutting with electrically operated machines. When this is done, the two compressors will be abandoned and steam for operating the low-pressure turbine will be obtained from the hoisting engine, the engine driving the 170-kw. generator and the mine fan engine. As the turbine is of the mixed-pressure type, it may be operated on live steam at periods when insufficient exhaust steam is available. The turbine drives a 500-kw. 250-volt direct-current compound-wound generator through reducing gears, the reduction being from 3600 to 720 revolutions per minute.

The condensing equipment consists of a Rees Returbo installation taking water from the spray pond and returning it through 60 nozzles. It is capable of producing 28 in. of vacuum, referred to a 30-in. barometer, the year around and a great part of the year produces a vacuum of 29 in. and better. The condenser is driven through gears by a steam turbine, and the exhaust steam is delivered to the 500-kw. low-pressure unit.

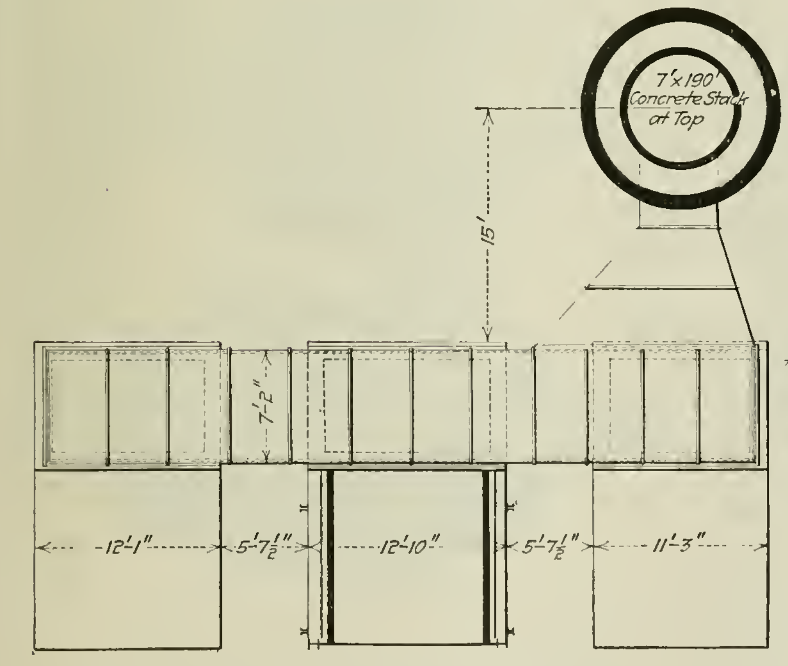
As shown in the layout drawing, steam from the two compressors passes through a vertical receiver oil separator and thence through a 14-in. flow valve to the low-pressure turbine. A 5-in. live-steam connection is made from the new steam header to the turbine to carry the load when sufficient exhaust steam is not available. At the top of the receiver oil separator a 14-in. relief valve allows any excess steam to pass to the atmosphere. The condenser is also provided with a 12-in. automatic relief valve.

NEW EQUIPMENT REDUCES LABOR COST

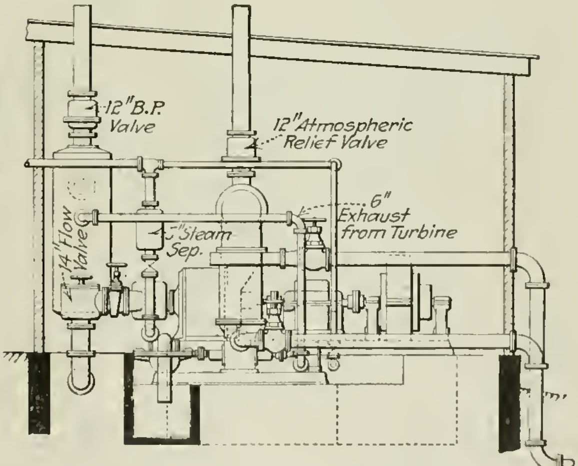
By the installation of this new equipment the number of firemen was reduced from nine to four and the ash wheelers to one, the latter reduction being due to the installation of a steam-jet ash conveyor. As the operating shifts at the mine are eight-hour periods and the day shift is the only period of heavy load, the ashes during the other two shifts are easily taken care of by the fireman operating the boilers. As a matter of fact there is sufficient ash storage under the boilers to allow accumulation for 16 hours.



PLAN OF ENGINE ROOM



PLAN OF BOILERS AND STACK



ELEVATION OF LOW-PRESSURE TURBINE

As a result of the improvements the coal consumption was reduced from 90 tons of No. 4 washed coal per day to 45 tons of No. 5 washed coal. At present prices this means a saving of approximately $135 per day.

The plant has been in operation for 21 months, and the owners claim that the improvements have already paid for themselves. Besides, by releasing the air compressors from supplying the mine pumps, the capacity of the mine has been increased from 2000 to 3000 tons of coal per day. This in itself is a great advantage at this time, when coal is in such urgent demand and the price is higher than it has been for years.

The Electrical Study Course—The Dynamo

Consideration is given to the generation of voltage in a two-pole machine having a ring armature, and the distribution of the current in the armature winding.

SO FAR we have only considered dynamos that have one coil of a single turn of wire on the armature. In the commercial type of machines the armature contains a number of coils. On the small-sized machines the armature is usually wound with a small number of coils having a considerable number of turns of small wire, whereas in the large-sized machines the armature is wound with a large number of coils of large wire having a small number of turns, usually one turn made from a copper bar. We have also learned that there are two types of armatures; namely, ring and drum.

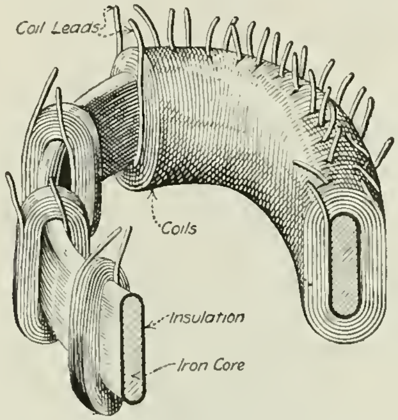


FIG. 1. RING ARMATURE IN SECTION

The ring armature consists of an iron ring with the coils wound around it as in Fig. 1, where the coils on a drum armature are placed on the surface of the core, or in slots in the surface of the core, as in Fig. 2. Fig. 2 shows three coils in place and how the coils fall over one another to form a complete winding, as in Fig. 3. In the drum-type armature the spread of the coils—that is, the number of slots spanned by a coil—is determined by the number of poles. For example, in Fig. 2 the coils span approximately one-quarter of the core, which would indicate that this armature is intended to operate in a four-pole field frame. In the ring armature the distribution of the winding on the core is the same, irrespective of the number of poles, where in the drum armature the coil spans approximately the distance between the centers of adjacent poles.

Although there is no difference in the two types of armatures so far as voltage generation is concerned, when it comes to a consideration of the various elements that take place in the windings, the ring type lends itself much more readily to a theoretical discussion, therefore will be used in our consideration of this subject.

In Fig. 4 is shown, diagrammatically, the complete layout of a dynamo-electric machine having an armature of the ring type. Coils of wire, designated field coils, are placed on the polepieces. The winding on the armature is shown, for simplicity's sake, to be continuous for the entire circumference of the core and closed on itself, with a tap taken out at each turn of the winding to a bar or segment in the commutator. This winding could have been shown grouped into coils, as in Fig. 5, with the leads of each coil coming out to two commutator bars, as shown, which is generally the way the job is done in practice, but for our purposes Fig. 4 is better suited. The winding in Fig. 5 has twice as many turns as that in Fig. 4, consequently, will generate twice the voltage under a given condition of speed and field strength.

In Fig. 4, if a current is caused to flow through the field coils in the direction shown, it will cause the top polepiece to become south and the bottom one north polarity, and the magnetic flux will flow in the direction indicated. Then, if the armature is revolved in the direction of the curved arrow, the conductors under the S pole will be cutting the lines of force in a left-hand direction, while those under the N pole will be cutting the flux in a right-hand direction. The lines of force are moving upward, from the N to the S pole, in each case, therefore, by applying the rule for determining the direction of electromotive force, it will be found that in the conductors under the S pole the voltage is down through the plane of the paper, while in the conductors under the N pole it is toward the reader, as indicated by the arrowhead. It will be seen that all the voltages generated in the various conductors under the S pole are in series assisting one another, likewise under the N pole. Therefore, the sum of the voltages generated in the conductors under one pole is the voltage that will appear at the brushes when the latter is in the position shown. It will also be seen that the voltage in the windings under the N pole opposes that generated in the conductors under the S pole. Since the voltages

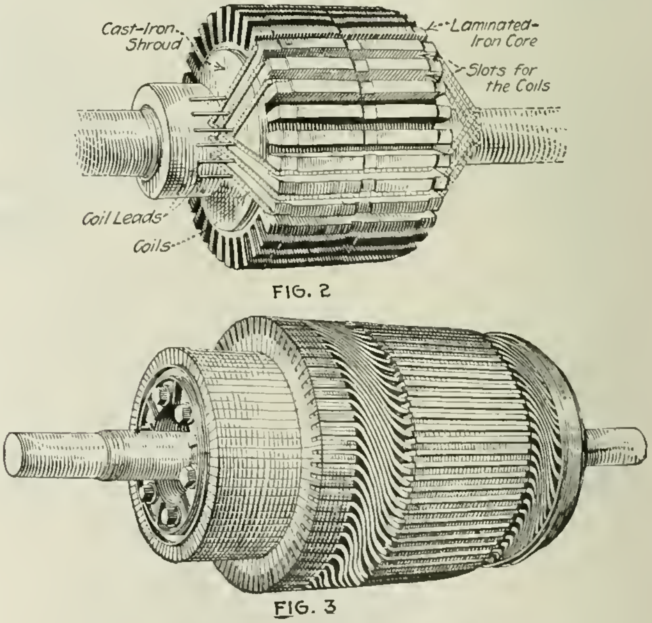

FIG. 2

FIG. 3

FIGS. 2 AND 3 DRUM-TYPE ARMATURE

in the two halves of the windings are equal, or at least should be, no current flows in the winding as long as the circuit is open between the two brushes.

The question of electromotive-force generation was discussed to considerable extent in some of the earlier lessons, and it was pointed out that the device which supplies the current to the circuit does not generate the current, but produces a voltage that causes the current to flow in a conductor when it is connected between the positive and negative terminals of the source of voltage. This is just the condition we have in Fig. 4. The conductor on each half of the armature cuts the line of force and generates a voltage; however, the arrangement of the winding is such that the voltage in one half opposes that in the other half, and no current can flow around in the winding until the brushes are connected to an external circuit *C*, as in Fig. 6. In the figure the external circuit is shown on the center of the commutator; however, this is for simplicity's sake only, as this circuit might be a motor or a group of lamps, or any device that requires an electric current for its operation, and might be located at a considerable distance from the machine.

The generator in an electric circuit is the same as a pump is in a circulating system. The pump does not generate the fluid that it causes to flow in the system, but creates a pressure that causes the fluid to flow in the pipe line. Likewise an electric generator only produces the pressure that causes the electric current to flow in the circuit.

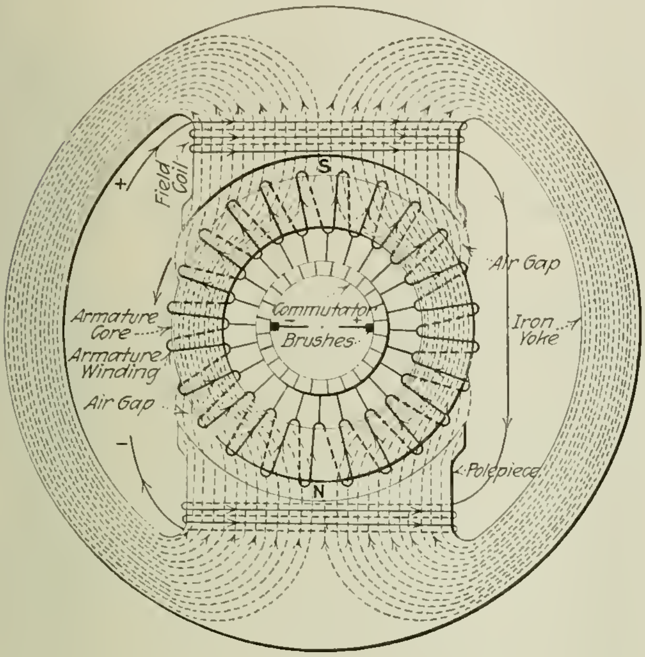

FIG. 4

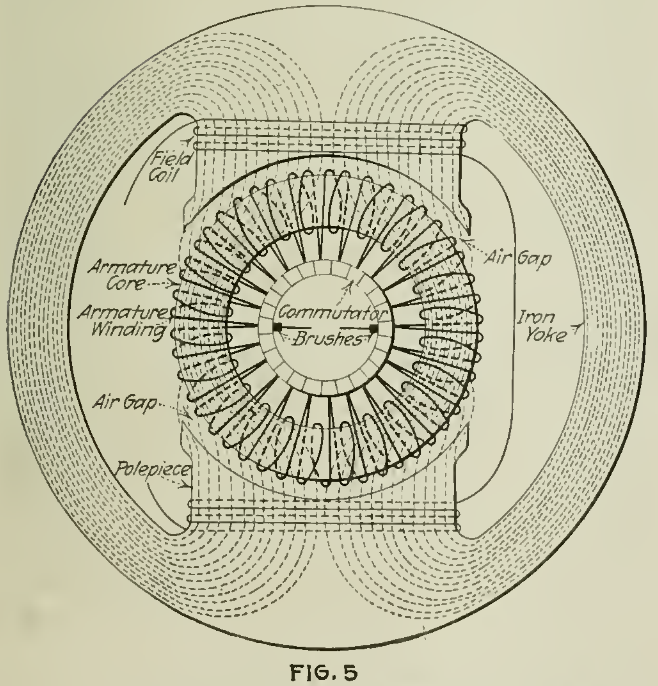

FIG. 5

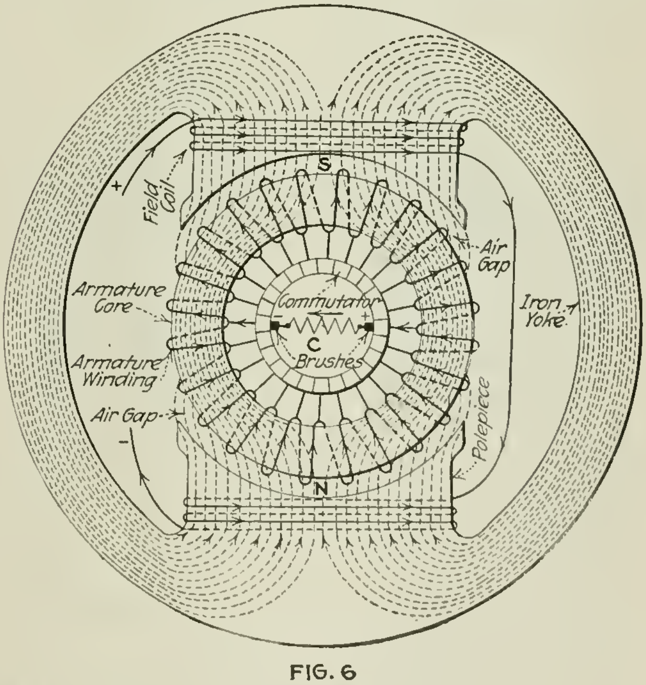

FIG. 6

FIGS. 4 TO 6. DIAGRAMMATIC REPRESENTATIONS OF A RING-ARMATURE TYPE GENERATOR

The two halves of the armature windings in Figs. 4, 5 and 6 are similar to two voltaic cells in parallel. In Fig. 6 it will be seen that the electric pressure generated in the conductors under the N pole causes a current to flow out from the positive brush through the external circuit *C* and into the negative brush, as indicated by the arrowhead; likewise, for the conductors under the S pole. Since the two halves of the windings are in parallel, the voltage appearing at the brushes will be that developed in one half of the winding, just as when two voltaic cells are connected in parallel—the voltage of the group is equal to that of a single cell. Also, each half of the winding will supply one-half of the current in the external circuit; that is, when the armature is supplying 30 amperes to the external circuit *C*, 15 amperes will be flowing in the conductors under the N pole and 15 amperes in the conductors under the S pole. This is again the same as when two voltaic cells are connected in parallel and supplying current to a circuit—one-half of the current is supplied by each cell.

All the foregoing discussion has been in reference to two-pole machines. The general principle applies to multipole machines, although the division of the current may be somewhat different in the winding, as will be seen in our discussion on this subject in future lessons.

Fig. 7 is a layout of problem 1 given in the last lesson. This circuit may look complicated, nevertheless it is the equivalent of three resistances in parallel. There are three circuits from A to B: One directly through $r_5 = 6$ ohms; another, which we will call R' through r_1 and r_2 in series $= 2.5 + 7.5 = 10$ ohms; and the third, which we will designate as R'' through r_3 and r_4 in series $= 6 + 9 = 15$ ohms; that is, three resistances R', r_5 and R'', in parallel, of 10, 6 and 15 ohms respectively. That there are three circuits parallel is indicated by the flow of the current shown by the arrows.

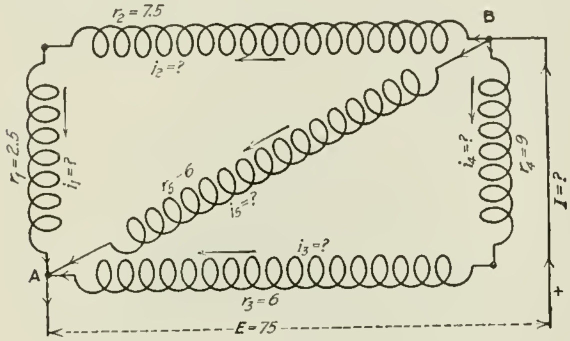

FIG. 7

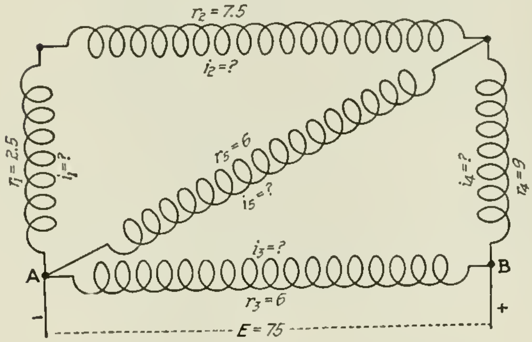

FIG. 8

FIGS. 7 AND 8. COMPLEX CIRCUITS

The joint resistance of the circuit is

$$R = \frac{1}{\frac{1}{R'} + \frac{1}{r_5} + \frac{1}{R''}} = \frac{1}{\frac{1}{10} + \frac{1}{6} + \frac{1}{15}} = \frac{1}{\frac{10}{30}} = \frac{30}{10} = 3 \textit{ ohms}$$

The total current flowing in the circuit equals total volts divided by the joint resistance of the circuit, or

$$I = \frac{E}{R} = \frac{75}{3} = 25 \text{ amperes.}$$

$$i_1 = i_2 = \frac{E}{r_1 + r_2} = \frac{75}{2.5 + 7.5} = 7.5 \textit{ amperes;}$$

$$i_5 = \frac{E}{r_5} = \frac{75}{6} = 12.5 \textit{ amperes;}$$

$$i_3 = i_4 = \frac{E}{r_3 + r_4} = \frac{75}{6 + 9} = 5 \textit{ amperes;}$$

and the total current equals the sum of the three, or 7.5 + 12.5 + 5 = 25 amperes, which checks the foregoing calculation.

In problem 2 of the last lesson the circuit took 15 hp. when 115 volts was applied to it. To find the current, first find the watts, which equal $W = \text{hp.} \times 746 = 15 \times 746 = 11{,}190$ watts. Then $I = \frac{W}{E} = \frac{11{,}190}{115} = 97.3$ amperes. This might have been expressed as $I = \frac{\text{hp.} \times 746}{E} = \frac{15 \times 746}{115} = 97.3$ amperes.

The total resistance $R = \frac{E}{I} = \frac{115}{97.3} = 1.18$ ohms. R also equals $\frac{E^2}{W} = \frac{115 \times 115}{11{,}190} = 1.18$ ohms.

In Fig. 8, in addition to determining the values indicated by the interrogation marks, find the joint resistance of the circuit.

Engine Troubles Due to Carelessness

By Charles W. Oakley

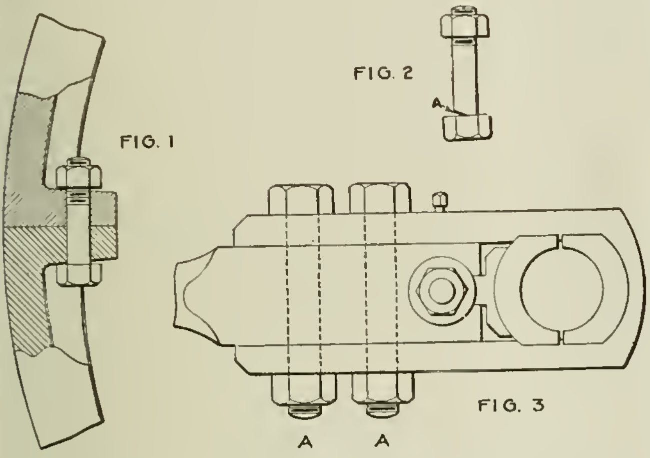
There is a weakness on the part of many engineers to consider the man sent out by the builder to erect an engine or turbine as almost infallible. While this man is usually a thorough mechanic, conscientious and painstaking in his work, occasionally one is met whose idea of his own importance either overcomes his judgment or else takes the place of the knowledge and experience which he is supposed to have. This is due in a large measure to the attitude of many superintendents and managers, who, because the erecting man is invested with considerable responsibility, defer to him and seek his opinion not only on questions pertaining to the machinery being installed, but on matters concerning the operation of the plant, with which the chief engineer is much better acquainted and probably has vastly more experience.

A case of carelessness on the part of an erecting man, which might have resulted in a disastrous accident, occurred in putting together a flywheel weighing about sixteen tons, made in halves and bolted through flanges at the rim and the hub. When the wheel was put on, the heads and nuts of the bolts had a bearing on the flanges at one side only, as shown in Fig. 1. The engineer protested to the erecting man, who explained that it was unnecessary to face off the flanges to secure a full bearing, as it was the custom of his firm to make the bolts and flanges several times as strong as required, and therefore no harm could ever occur. However, he suggested that copper washers be placed under the heads and nuts, explaining that the copper would allow the heads and nuts to bed themselves until a full bearing was obtained. This was done, the bolts being pulled down considerably tighter than would have been necessary had they had a full bearing on the flanges. The engineer was then instructed to tighten the bolts at intervals, after running a few days, and eventually they would have a uniform bearing.

The engineer obeyed his instructions; but one morning shortly after the engine had been put in service, when he started to tighten up one of the nuts, he was surprised to find that it turned quite easily. The bolt, on being removed, was found to be cracked about halfway through under the head, as at A, Fig. 2. Examination of the other bolts disclosed incipient fractures in three of them. It is hardly necessary to describe what would have happened to that wheel before many hours.

No time was lost in getting the engine builders on the job and having them face off the flanges until the new bolts which were secured had a proper bearing on the flanges.

One of the errors made by engineers, and sometimes by erecting men, is the improper fitting of bolts. Some engineers are of the opinion that so long as a bolt is amply large for the work it has to do, it is of little consequence whether it fits closely in the hole or not. They argue that the job is all right because the nuts are drawn up tight. Later on, evidence of shifting of the parts that are bolted together may be detected through the appearance of rusty oil at the joint or under the bolt head. Whenever an indication of this kind appears, the nut should not be tightened further, but the bolt should at once be removed and an examination made to ascertain whether there is any fracture of the bolt or the casting. The hole should be tested for alignment, to see whether a bolt the full size of the hole will go all the way through. If not, the parts should be held firmly together in their correct relative positions and the hole should be carefully reamed out. Then a bolt of proper size should be obtained and turned to fit the reamed hole snugly.



FIGS. 1 TO 3. EXAMPLES OF CARELESS FITTING

Figs. 1 and 2—Effect of poor bearing of flange bolts. Fig. 3—Design of connecting-rod end.

In making a flywheel or a large belt wheel in two or more sections, it is customary to plane off the joints and flanges of the wheel, and then bolt the sections together before turning and boring the wheel. It is rare, however, that a wheel is bolted together as firmly for this purpose as it is when placed in position for service; consequently, when the wheel is put in place on the shaft, some slight distortion frequently occurs at the bolt holes, especially when the arms are bolted between hub flanges. Great care should be taken to have the bolts well fitted to holes reamed out carefully, and no springing, prying or drifting should be allowed in making up these bolted joints. Not only must the head and nut of each bolt bear fully and squarely on the surfaces, thus insuring a straight pull on the bolt, but the shank of the bolt should present its full shearing area at all points in the joint.

Other parts of the engine besides the flywheel are susceptible to danger and trouble from ill-fitting bolts. To illustrate, the crosshead end of a large connecting-rod developed a very annoying pound shortly after it had been fitted with a new set of brasses. Upon taking down the connecting-rod at the crosshead end, which was of the design shown in Fig. 3, it was discovered that the bolts *A* were slightly loose in their holes and had necks cut into them by the strap, thus allowing some movement of the strap.

When this condition of affairs was pointed out to the engineer, he confessed that as the brasses had been found slightly large between the strap and the wedge, he had filed the bolts down so that they would pass through the holes in the rod end, thus avoiding the trouble of taking out the brasses again to plane them off. It was necessary to secure new bolts and ream out the holes in the strap and rod to fit. The pound then disappeared.

In erecting a large engine it is usual to locate the pillow block or pedestal on the sole plate by means of dowel pins, as shown at *A*, Fig. 4. The sole plate *B* is first lined up and leveled properly, and when the foundation has hardened sufficiently the pedestal is set in place over the dowel pins and held firmly by means of the anchor bolts *C*.

It is inadvisable to have the anchor bolts fit closely in the holes in the sole plate and pedestal, as shifting of the bolts while the foundation is being built would prevent the placing of the pedestal over the bolts. To allow for slight lateral movement, therefore, they are usually set in boxes *D*, with pockets *E* in the foundation at their lower ends, so that a wrench may be inserted to remove the lower nuts and allow the bolts to be drawn up and replaced in case injury or breakage requires their renewal.

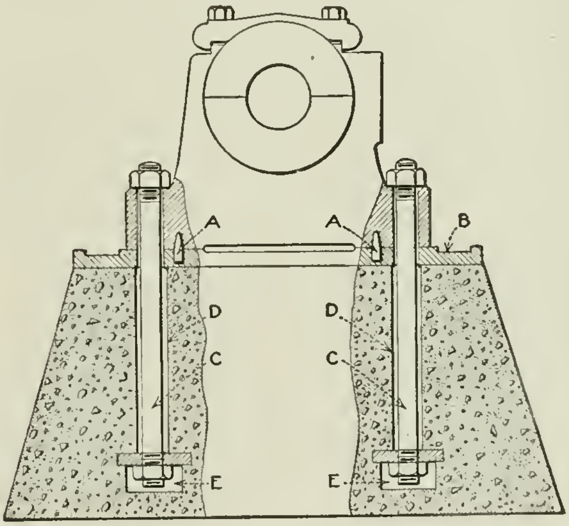


FIG. 4. DOWEL PINS TO PREVENT PILLOW BLOCK FROM SHIFTING

Allowing the anchor bolts to become loose permits the pedestal to work back and forth, slightly at first, but gradually increasing in movement until the dowel pins are sheared or broken off, leaving the position of the pedestal dependent entirely on the tension of the anchor bolts. A serious accident resulted from this cause some years ago. The movement of the engine frame caused such excessive vibration of the governor standard that it broke or sheared off the studs securing it to the engine frame. The breaking loose of the governing mechanism resulted in a runaway that wrecked the entire plant.

What of the Labor Situation?

WHAT of the labor situation? Let us face the facts. Labor is stronger today than ever before. It has tremendous power. It can for short periods stop industry. Within reason, it can force almost anything it will. If it goes to extremes, the rural communities and large groups in the cities will rise to check and thwart its demands. Nevertheless, if misguided, it can work serious hardship. What, then, is its purpose? How will it use its power? Is it bent on a rule-or-ruin policy? Or, seeing the good in the existing order and conscious of the sure control that lies in the mass of the people, is it desirous of compromise?

Emphatically the latter is true—speaking as to the majority of the acknowledged labor leaders. Their desires cannot be realized unless capital comes half way. If capital resists, if it is represented—or rather misrepresented—by those who take an autocratic stand, it will force millions into the radical wing of the labor party, it will add fuel to fires already burning.

These are not the days for sugar-coating the pill. The coward will cringe from facing the facts. He will roundly condemn those whose object is to save him—and with him the essential elements in the present social order. Charles M. Schwab said a few days ago that the worker was to dominate the world. A more temperate statement is that of former Supreme Court Justice Hughes, a student of industrial relations, accustomed to consider and weigh. Before the New York Bar Association last month he said:

"Individual privilege [in the future] will have to show cause before a public to which old traditions are no longer controlling—a public trained in sacrifice—which will enforce its own estimate of the common right." And again he said: "The present exercise of authority over the lives of men will hereafter find its counterpart in a more liberal exercise of power over the conduct, opportunities and possessions of men."

Mr. Schwab and Justice Hughes had the courage to recognize the changing order. Narrow minds, however, will rail and rant, urge that capital prepare to fight for its position, and declare that no man shall dictate how they shall run their plants. Such minds are not changed by dissertations on the reasonableness of the new order, which decrees that the public good shall take precedence over private gain, that the public cares for the individual and demands that he have a voice in determining the conditions under which he works.

It is a matter of indifference, in any event, what the individual thinks as to the soundness of the coming order. We are in a new era, in fact. Witness the fires raging socially in Russia and now kindling in Austria and even in Germany. Note the power which labor has in England.

We are in and of the world. The power drifting to the workers here is part of the world tide. Whither will it lead us?

Even as there are standpat autocrats as well as men of enlightenment among employers, so there are radicals and conservatives among labor. The autocrats on the one hand and the radicals on the other are the extremists. If they are left to lead us out of the difficulties, we shall have an arming for conflict and a great catastrophe. It is for those who see the light to compose the differences—the moderates among the employers, the conservatives among the workers.

These wings of the opposing parties can reach a working agreement. They must come together in order that the extremists may be disarmed—aye, that they, and the country with them, shall be saved from their own madness. The final result will work for the greater good of all. "Harsh changes are necessary," said Mr. Schwab, "but they will be more than repaid not only materially, but in happiness and contentment."

Practically, what is coming out of the present economic crisis? Detailed predictions are dangerous. This much is certain: (1) Labor will demand and get a larger share of the profits of industry, and (2) it will demand a voice in each industry in determining the conditions under which it shall work.

Is that a cure-all? Will all labor difficulties be then composed?

Not so. There is not an absolute unity of interest; there cannot be a permanent peace. All we can hope for is compromise under conditions that obtain today. When conditions change, there will be a new compromise, succeeded by another and another and still another. But the present compromise will be the greatest for many a day, for it will definitely establish labor's voice in the control of industry.

And what of the industries that pay a bare 4 or 5 per cent. on a fair or low valuation of investment? Bankruptcy or a reduction of overhead through increased production. These are the only alternatives.

And what of efficiency, now at a low mark in industrial plants? Education is the answer—education, through participation in management, regarding the factors which affect profits; education which will engender a sense of responsibility for the success of the industry, a realization that there can be no labor prosperity without industrial prosperity—a realization that will be turned into effective action by confidence that labor will get "its share" of the profits it helps to create. A long process, yes, but a necessary one.

And efficiency is a shoe that both parties can wear. Management inefficiency more than matches, count for count, labor inefficiency.

Radical talk this? Yes, if you will have it so, but read again the words of Charles Schwab and of Justice Hughes.

Shall we fear to face the facts? Shall we, by ignoring conditions that the merest numskull can appreciate, drift into anarchy? *Laissez faire* and "last-ditch resistance" both lead to that end.

Soon there will meet in Washington a Labor Policy Board. It will hold the balances for our industrial peace. There must be give and take—compromise. Both sides must surrender much that they value highly. Far-seeing employers are ready to make sacrifices. So, too, are the forward-looking labor leaders. The interests of the country demand that both sides look carefully to it that they be not misrepresented. And above all let both be prepared for large concessions. In that direction lie peace and the country's good.—*E. J. Mehren in "Engineering News-Record."*

Editorials

What Is Labor Unrest?

THE human mind is the most complex piece of mechanism in the world. It is the master mechanism. How it works nobody knows. What it will do individually and collectively under any given conditions nobody knows—not even its owner.

The man who digs your ditches has depths you cannot plumb. You see him come and go every day and his coming and going become a part of your daily habit of thought, like the coming of your morning newspaper. Some day he doesn't blend with the scenery as you are accustomed to viewing it. Unknown to you there has been some crisis in his life; his mental depths are in turmoil; age-old questions come to the surface. Placidity becomes turbulence and you are annoyed—unless you have become similarly turbulent yourself, in which event you are not annoyed. You understand.

Your ditch digger has thousands of years of his ancestors' life and thoughts and yearnings slumbering in his soul and speaking when he is roused. He has not always been a ditch digger. Some centuries past in Asia Minor, in Greece, in Italy, along the whole line of civilization's push upward, he has been oppressor and oppressed, just as you have been—mostly oppressed, for the oppressed have always been in the majority.

One life begins and ends; but the blood-flow is continuous from generation to generation. The thousands of years behind us speak in us and to us and through us every day. The greatest thinkers, ancient and modern, affirm this.

There has been more stirring of the human depths since August, 1914, than there had been in the whole period since our Civil War. All of our accustomed grooves have been upset. In our social bearings we lack a sureness of direction. The guide posts have become weather vanes. Our placid gray matter has been set seething. The former smooth surface of our minds which reflected the current weather, the passing clouds and the orderly seasons, is turbulent; the sediment of the centuries is bubbling to the surface from the depths.

We get into channels. Channels are comfortable. They fix direction. Where you are going doesn't worry you. It suffices that you are comfortably on your way. Then something happens and destroys the channel. You and your ditch digger face each other with the eternal question of your mutual relationship in your eyes. The thousands of years back of each of you is compacted in the look. *And you couldn't phrase the question in words if you tried.* You don't try, either of you. Instinctively you know it, but to save your souls neither of you could say it.

If you tried to say it, you would both use the words you used in the channel—wages, open shop, cost of living. Especially the ditch digger would. He couldn't phrase the concentrated protest of ten thousand years in a moment of crisis any more than he could think it logically in a year in the channel. It is too big, too overwhelming, too much a rising of his whole being. So when you ask him what he is turbulent about, don't quibble about the lack of a clear-cut answer. It can't be made; you couldn't make it yourself. But if you want his answer, get it in his reactions. Hear him give approval to war against the Kaiser; note the set of his features when the war profiteer is mentioned; watch him as he listens by the hour to the man you would call an agitator; catch his constant sanction to the opportunities open alike to everybody and his equally constant suspicion of opportunities not possible for *his* children. The public schools are never afraid to go direct to the people for money; the universities are.

Business based on the idea of maximum cash returns to the owner, at any cost to competitors, to labor, to the social order, to the Government, was bound to be a boomerang.

The labor unrest is the instinctive protest of ten thousand years against all this.

New Jersey Plants Closed from Lack of Coal

NOTWITHSTANDING the fact that suspension of heatless Mondays was announced on February Thirteenth, by Fuel Administrator Garfield, with the reservation, however, that the suspension order might be revoked before the ten-week period expired if a return of cold weather should bring another breakdown in railroad transportation, it strikes one as being somewhat premature when viewed from the state of local conditions and those prevailing in New England.

Although heatless Mondays have been abolished, a large number of industrial plants in northern New Jersey were forced to stop or curtail work the day prior to the Fuel Administration order, because of the cutting off of electric power by the Public Service Electric Co. of Newark and the Public Service Corporation of Jersey City, due to lack of coal.

Many of the plants affected have important war contracts, and about 50,000 employees were made idle. It was announced by officials of both companies that the shutdown would probably continue until February twentieth.

It is believed that the manufacturers in this district have cause for complaint because of the alleged failure of the Fuel Administrator to keep his promise, made about the middle of January last, to the effect that the Public Service Corporation would be supplied with enough coal to keep it going. It is understood that a delegation from Jersey City, Hoboken, the Bayonne Chamber of Commerce and the Newark Board of Trade visited the Washington fuel authorities and were told by them that arrangements would be made with War and Navy Departments whereby the coal would be shipped ostensibly to the army, but would be delivered in Jersey City to the corporation. The corporation officials declare that this plan was never carried out properly, that although for a time they got coal from what is known as the tidewater pool, a few days ago the pool refused to deliver coal.

It seems incredible that such a situation should have been allowed to come to a head as to compel the shutting down of a chain of large power plants, especially when so many companies are using their current for manufacturing war materials.

Improve Plant Efficiency

SHORTAGE of labor limits the output of the mines, and scarcity of cars hinders coal distribution. With the demand far in excess of production, there is one way that will help to relieve the shortage. Save coal at home and, more important still, save it in the power plant. Make nine pounds of coal do the work ten pounds did before, and then see if the economy cannot be bettered. There is many a plant in which this ten per cent. saving might readily be increased to thirty, and in some cases it would be possible to cut coal consumption in two without reducing the output.

It is not a question of installing new and more efficient machinery. Manufacturing and transportation facilities are not available, and if they were, the time element is too pressing. Relief is needed at once. The solution is to improve the plant as it stands. The worse the condition the greater the saving possible. The opportunity exists and all that is needed is intelligent attention by every power-plant owner and engineer in the country.

A real engineer well knows what is needed. He will look to air leaks in the boiler setting and stop steam and water leaks in the piping. He will adopt proper firing methods for the coal he is burning, see that the draft is right and keep the heating surface free from soot and scale. All equipment in the engine and pump rooms will be kept in good order. The valves will be properly set, and the bearings will be kept cool by sufficient lubrication. In a word, the plant will be maintained in the "pink" of condition.

All this necessitates a competent engineer, a good fireman, a system of records showing accurately what is being done and the necessary instruments with which to obtain the operating data. And here is the owner's opportunity. He must choose his man wisely and then provide him with every facility possible that will help to produce the most efficient results.

In those plants not containing mechanical stokers the fireman is the biggest single factor to be considered. Good men of this trade are scarce, and it is a question of educating the material at hand. Higher-priced fuel has helped to eradicate the idea that the fireman is a common laborer subject to the treatment of a roustabout. As fuel prices go up the margin between good and indifferent work means more and more of the firm's money. It will be found cheaper to educate the fireman than to pay for coal, and the laborer will be raised to the plane of a skilled workman. In this process valuable information may be obtained from the Bureau of Mines, various schools and engineering associations will contribute to the cause, and *Power* stands ready to supply all information at its command.

Prompt action by every power plant in the country would easily increase the average economy ten per cent. It would mean millions of tons of coal for war purposes, resulting in more rapid mobilization of men and supplies at the front by our own country and our allies. It would contribute toward shortening the war and at the same time mean a saving to the power-plant owner. This is no sacrifice. Like buying a Liberty Bond with interest and principal returnable, it is the duty of every patriotic engineer and power-plant owner to contribute to the cause.

Names! Names! Names!

THE following appeared in the New York *Sun* o February 15. Why is it that "The names have not been made public"?

> COAL MEN INDICTED
>
> *Tennessee Operators and Dealers Held for Food Law Violations*
>
> Knoxville, Tenn., Feb. 14.—The Federal Grand Jury here today returned twenty-three indictments against forty-seven defendants, including coal operators, coal dealers and coal brokers of the east Tennessee field, charging violation of the food-control bill. The names have not been made public.
>
> The indictments include 163 counts. The cases will be called for trial here at the May term. The indictments resulted from investigations made during the last two months by the Department of Justice, which developed charges of violations of Government fixed prices and Fuel Administration order.

Give us their names.

Coal Piracy Under Ban

> Sale of rock and slate masquerading as coal is going to be discouraged, C. E. Robertson, deputy state fuel administrator, said today.
>
> "Within the past few days," he added, "this office has had rejected two cargoes of which an analysis showed 69 per cent. of rock and slate and only 31 per cent. of coal. The railroad companies carrying this coal notified the producers in Pennsylvania that no more cars would be furnished to them. If this stuff had been accepted by the consignee, it would have cost him $26 per ton for the coal in it."—*N. Y. Globe, Feb. 14.*

And even at that he could not have burned it.

There is nothing to be gained by holding meetings, writing papers and editorials to argue that the Monday closing orders of the Fuel Administration have saved little, if any, coal. Their object was not to save coal, but to relieve the bunged-up conditions of the railways. It is a pity that some of these intellectual giants cannot see how absurd some of their advice and comments appear in the light by which those who have great responsibilities are doing big things.

The *Engineering and Mining Journal* will say the following, editorially:

> The days of suspended industry in February may or may not be costly, but it is certain that they were not so expensive as the New York dailies represented last Sunday, on the authority of the *Black Diamond*. They put the loss for eight days at $4,344,000,000, which would be $543,000,000 per day, or at the rate of $162,900,000,000 per annum, reckoning 300 days. Inasmuch as the gross volume of business in the United States in 1917 is estimated at about $50,000,000,000, there is manifestly something wrong in estimating the loss of about eight per cent. of that sum in eight days.

Correspondence

Why Hot-Water Pipes Pit

On page 824 in the issue of Dec. 18, 1917, a description was given of the pitting of steel pipes used for steam and hot-water lines. Two instances were given, and the question was asked, "What is the reason?"

There is a possibility, as mentioned in the article, that there was originally in the steam pipe a pin-hole through which the steam escaped, gradually wearing the hole larger and larger and that it was, therefore, not a case of corrosion but of erosion. The other case, however, is typical of corrosion in hot-water lines, which is one of the everyday troubles of power-plant engineers and is satisfactorily explained by the electrolytic theory of corrosion. According to this theory corrosion is caused by electric currents emanating either from outside sources or in the material itself. In the latter case the elements necessary for corrosion to occur are as follows: (1) Impurities or other conditions in the metal, causing different electrical potential in adjoining areas thereof; (2) an electrolyte—commonly water; (3) a depolarizer—air or oxygen. With these conditions prevailing, a current is set up which dissolves the metal at the electropositive pole, resulting in oxidation and precipitating of rust at this point, where the pit will subsequently be observed.

It will be seen that if oxygen can be excluded from a water line, corrosion will not take place; likewise that corrosion will to some extent be accelerated or retarded according to the amount of free oxygen contained in the water. From the oxygen content of the water viewpoint one may reason out the relative corrosive effects of water, steam and moisture in various forms, and it will be seen from the following that the corrosion in hot-water lines is, in the light of the electrolytic theory, calculated to be very severe, agreeing with actual experience. Hot water, under certain conditions, as will be explained, is very destructive to the life of ferrous metals.

The experiments of Heyn and Bauer in 1910 indicate that the corrosion of iron in hot water increases with the temperature, reaching its maximum at about 140 deg. F., where the effect is about four times as great as at normal temperatures. Above 140 deg. the corrosion decreases with increase of temperature, and above 176 deg. the falling off is rapid and the corrosion should be very slight at the boiling point (212 deg.) because of the expulsion of oxygen from the water.

When iron is immersed in hot water, there are opposing forces to be considered:

1. Corrosion should be increased because: (a) The conductivity of the water as an electrolyte becomes progressively greater with increase of temperature to the boiling point. At this point it may be several times as great as at normal temperatures, and thus there may be several times the current density with its equivalent solution of iron for the same potential difference set up between the iron and any electronegative substance. (b) With rise of temperature there should be increased speed of reaction between the iron and oxygen in the formation of the rust.

2. Corrosion should be decreased because: The solubility of oxygen in water decreases with rise of temperature, becoming nil at the boiling point.

The amount of corrosion at any temperature will depend on the balance of these forces. As indicated previously, the observed effect is an increase to a maximum with subsequent decrease from this temperature to the boiling point of water.

In hot-water supply and heating systems the corrosive action will depend largely upon conditions of design, installation and operation. At best there is a tendency for marked acceleration of corrosion because of the increased electrical conductivity of the water up to a certain temperature; also because of the evaporation of the water—as in all closed circulating systems—which will result in increased concentration of salts in solution as compared with the natural supply. If an open system is used, where the water is brought to the boiling point and the greater part of the liberated oxygen is allowed to escape before entering the pipe system, corrosion may be very much reduced in spite of other influences in its favor. But with the customary closed system conditions could hardly be more favorable for maximum effect, owing to the accelerating influence of high temperature and probable concentration of salts in solution, coupled with a maximum content of oxygen, since the latter cannot escape from the closed system and is forcibly kept in solution by the relatively high working pressure.

The electrolytic theory of corrosion, or the difference of electrical potential in adjoining areas of a metal, may, as mentioned, be caused by impurities contained in the metal. On this theory it might be thought that high purity of metal would prevent, or at least greatly reduce corrosion. But the high-purity commercial irons apparently do rust just as quickly as ordinary steel, and metallurgists were therefore forced to look for other causes besides high purity. They then discovered that different polarity, causing electrolytic action, may also be due to: (1) Distortion or unevenly strained parts in the metal (caused in pipe by applying a wrench in tightening a joint, bending the pipe or the like); (2) lodgment of foreign matter or mill scale on the metal surface.

In addition it has been found that rust is of a different electrical potential from that of iron or steel and, when once formed on the surface, becomes the cause of further rusting or pitting. In other words, rust breeds rust, becoming such an important factor in the progress of corrosion that original purity of metal and the other causes mentioned assume comparatively little importance. While the electrolytic theory of corrosion, when properly interpreted, is a valuable guide to the understanding of the subject, it cannot be used for the purpose of reasoning out how any metal of a given composition will behave in actual service. Experience with the metal under service conditions is the best guide. The metal may, for instance, be very impure, like cast iron, and yet be fairly rust-resistant. This is assumed to be due to the barrier action afforded by these very impurities, principally the graphitic carbon, which in itself is highly rust-resistant and protects the underlying iron from corrosion by preventing penetration of the water or oxygen. In respect to the nature of other forms of iron considerable confusion exists, and the following may therefore be in order:

By commercially "pure iron" we understand certain products of the openhearth processes which should more properly be called pure steel, for they lack both the graphite contained in cast iron and the slag contained in genuine wrought iron. We know that wrought iron is a very durable product in spite of the large proportion of slag which is incorporated in the pure iron, but we should not be misled into construing this as a contradiction of the electrolytic theory, for it is apparent that the slag, like the graphite in cast iron, being in itself a practically noncorrodible substance, must on account of its fine distribution, protect the underlying iron from corrosion.

A. M. Byers Co.
Pittsburgh, Penn.

Water for Air Pump

I would like to add the following to what the readers of *Power* have contributed to the subject of the source of water supply for the air pump of Mr. Forseille, as told by him in *Power*, Nov. 20.

The first change to make is to lower the strainers and then connect up the new proposed line to the intake of the strainers, with a gate valve in the line so as to cut out the new line when the slush ice disappears. This will melt the slush ice by mixing the water, and a temperature from 60 to 70 deg. F. can be held in the air pump intake water. The temperature of the intake should be below 70 deg. The pump gets more or less vapor or steam from the condenser, but as long as the temperature is kept below 70 deg. F. the efficiency of the pump will not be appreciably reduced. Cold water is two-thirds of the battle in condenser operation.

North Kansas City, Mo. P. B. Williamson.

Providing Stand-by Service

In an industrial power plant where only one generator was provided, on which the maximum load never exceeded 75 per cent. of the unit's rated capacity, it was getting to be quite a problem to find sufficient time to make the necessary repairs and adjustments. Somebody always requires light and power, and although the load was small on nights and Sundays, it nevertheless caused considerable inconvenience if the engine was shut down for any length of time. The management did not feel inclined to buy another engine as long as this one was not loaded up to capacity. The figures offered by a central station for stand-by service were such that they could not be even considered. The central staton offered to take the entire load at a reasonable rate, but as all the exhaust steam was used in the different heating and cooking processes in the plant, the engineer soon convinced the management that the central-station figures, no matter how attractive, would be an expensive proposition. It was now up to the engineer to provide, if possible, some sort of stand-by service, and he solved the problem as follows:

In the room adjoining the engine room, mounted on the wall between the two rooms, was a 15-hp. motor belted to a lineshaft. This machine was never run at night or on Sunday and was idle part of the time during nearly every day in the week. The motor had originally been used for a generator and had been driven by a small engine, which had been taken out and stored in the boiler room. The old engine was resurrected, cleaned up, adjusted, tried out and found to be in good condition. Holes were cut in the wall in line with the pulley on the motor, and the engine was placed on a concrete foundation built on the engine-room floor in such a position that the engine pulley was in line with that of the motor.

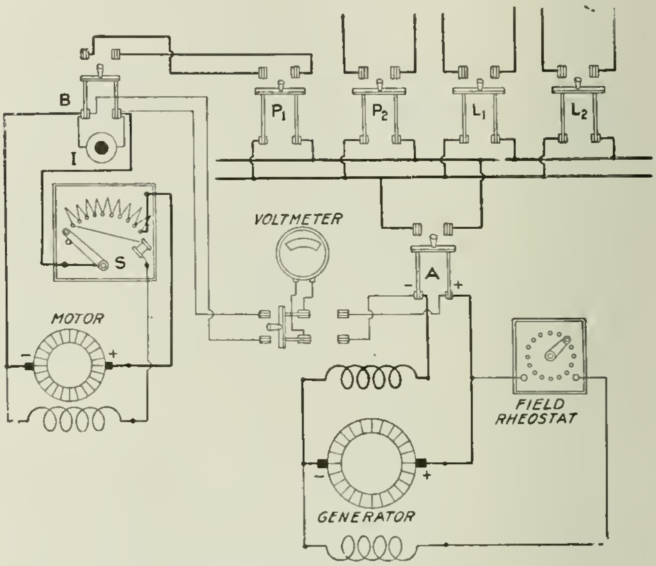

DIAGRAM OF GENERATOR AND MOTOR CONNECTIONS

The governor of the engine was adjusted so that, according to the pulley proportions, it should about run the motor at normal speed. A lamp *I*, as shown in the figure, was connected across the motor's switch to approximately determine the voltage of the motor while running as a generator.

When everything was ready, the engine was started and brought up to speed. The arm on the starting box *S* was placed in the running position, and soon the lamp *I* began to glow and came up to full brilliancy.

The switchboard was arranged with four switches, as shown. The two switches marked P_1 and P_2 supplied the power circuits; L_1 and L_2 the lighting circuits of the plant. There was only one other motor on the circuit P_1 besides the one being used as a generator, and the switch to this and the switch P_2 on the switchboard were blocked open so that no one could close them and throw excessive load on the emergency generating unit.

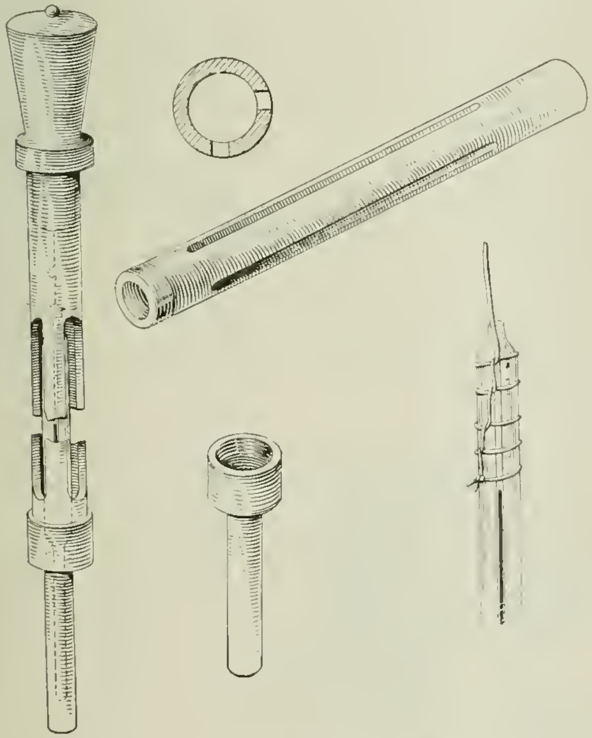
When everything was ready for the change-over, the motor switch *B* was closed, after which the generator switch *A* was opened and switch P_1 closed. The light grew a little dimmer, but this was soon remedied by adjusting the governor to increase speed of engine.

This stand-by unit was used several nights a week and nearly every Sunday for almost two years, when the load became so heavy on the main unit that a larger one had to be installed. The night engineer made another improvement by connecting the voltmeter to a double-throw switch, as shown, so that it could be switched from the main to the emergency unit when it was in operation, and the change-over was then made by paralleling the units, and therefore without interrupting the service. E. W. MILLER.

Minneapolis, Minn.

A Thermometer Guard

The illustration shows a serviceable thermometer guard which is simple to make and easily removed when not in use. Its essential parts are a piece of $\frac{3}{8}$-in. pipe 14 in. long and a wooden cap, the latter shaped to give oily fingers a secure hold and having a hole lengthwise through it for a wire or cord by which to support or move the thermometer. The pipe is threaded at one end and is attached to the ordinary thermometer cup by tapping the cup as shown. The other end is preferably reamed out smooth. Two $\frac{3}{16}$-in. slots are machined in the pipe 90 deg. apart. Then, with the pipe loosely screwed into the cup, one slot can always be turned to face the light. With a hole through the cap, the length of the wire or cord connecting with the thermometer is more readily adjusted than with a screw-eye or a transverse hole in the inner end of the cap.



GUARD TO PROTECT A THERMOMETER TUBE

If the eye is broken off the thermometer, tie a soft string around it, followed by a succession of half-hitches. Where excessive vibration endangers the thermometer, a turn of lampwick around its upper end or a small rubber band looped around a few turns will safeguard it. R. MATTHEWS.

Ithaca, N. Y.

Water-Jacketed Pillow-Block Cap

The pillow block of a 30 x 42-in. rolling-mill engine was in the habit of working hot; in fact, it required close attention and a lot of oil, and occasionally some cylinder oil, to keep it from smoking and throwing babbitt. It was cured by circulating water in the cored-out space in the bearing cap through a $\frac{1}{2}$-in. pipe. The bolt holes were in solid metal, and there was a vertical cast-iron partition in the middle, but the core was nearly the size of the babbitt area so that there was plenty of cooling surface. The rough core holes were stopped with wooden plugs into which small iron wedges were driven, on the principle of securing a hammer handle. Four holes for $\frac{1}{2}$-in. pipe were drilled and tapped and piped so that the water entered at the bottom of the space next to the flywheel, discharging from the top to the bottom of the crank side, as shown, and out at the top, after which the bearing was the least of the engineer's troubles. Induction Motor Would Not Operate on Direct Current

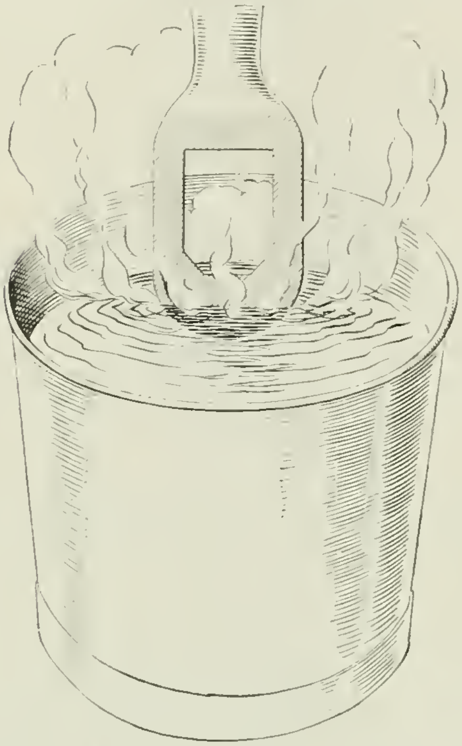
When it is considered that the counter-electromotive force in the armature conductors of a direct-current motor is generated by the conductors being moved across the magnetic field from the field poles, where in an induction motor, the counter-electromotive force is developed by the stator winding cutting the lines of force set up by the current in this winding, it is evident that the alternating-current motor will not operate on a direct-current circuit.

Some time ago, after making some repairs on a small alternating-current motor, I started to give it a running test from a double-pole, double-throw switch connected to a direct-current circuit on one side and an alternating-current circuit on the other. By mistake I threw the switch to the direct-current side instead of the alternating-current side, with the result that the fuses were immediately blown. After trying to make this test two or three times and failing, the motor was opened up and inspected for trouble, but everything was found in good condition. About this time it was discovered that the switch had been thrown to the direct-current side instead of the alternating. Upon assembling the motor and connecting it to the alternating-current circuit, it operated satisfactorily without any further trouble. C. R. BEHRINGER.

Schenectady, N. Y.

Shrinking the "Eye" of a Rod

I have received a great deal of useful information from *Power* and will, in turn, endeavor to supply something myself. I am a machinist and was called out on a job on a Corliss engine (18 x 42 in.) that had developed a bad pound, and I discovered that the brasses were loose in the rod.



EYE CONTRACTED BY HEATING AND COOLING

To save the customer buying a set of new brasses, I removed the old ones, took the rod to the shop and heated and shrunk it in the manner illustrated. When cooled, I found I had to remove nearly $\frac{1}{32}$ in. to refit the brasses.

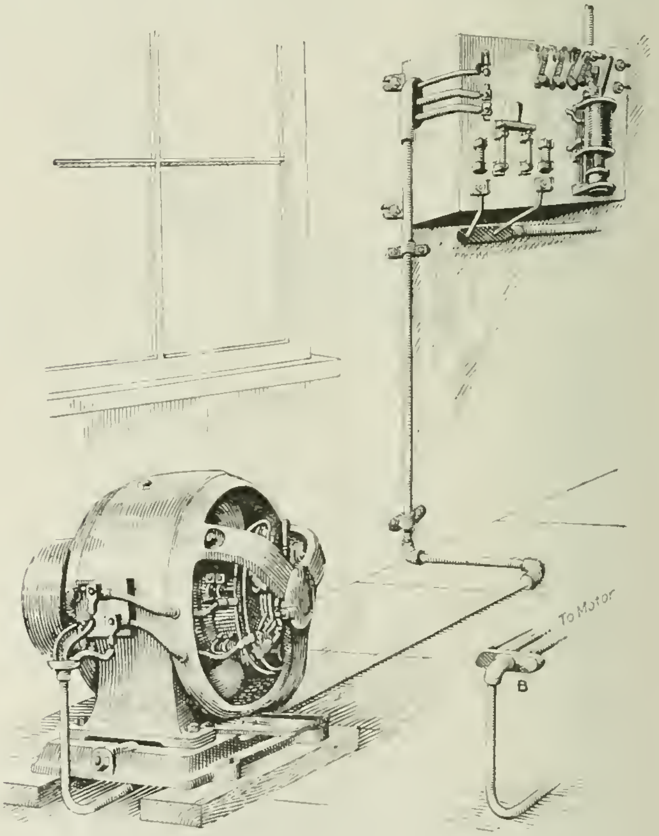
An Elusive Ground

A direct-current motor, controlled by an automatic starter, as in the figure, caused trouble by blowing its fuses. The wires from the controller to the motor were run in conduit, and a magneto test showed one of these wires to be grounded. A burned spot showed on the conduit near the control panel, about three inches from the end fitting. As this was believed to be the location of the ground, the wires were disconnected from the motor, and pulled about six inches out of the conduit at the control-board end, and were all found to be in perfect condition. Closer inspection showed the burned spot on the conduit to be on the outside only, evidently having been caused by a live wire coming in contact with the conduit at some previous time. With the wires in this position the magneto was again applied and all rang clear.

Next, the motor and control board were tested for grounds and found to be clear. Inasmuch as everything was now apparently in good order, the wires were again connected to the motor and upon starting all went well for a few hours, then the same trouble again occurred. The next thing done was to test each and every connection on the controller, all of which showed a ground that could not be located. After losing considerable time in this manner, the wires in the conduit were disconnected at each end and again tested, this time showing a ground on one of them.

The wires were then pulled entirely out of the conduit and found to be badly water-soaked, while the insulation was burned from one of them for a length of about four inches where the current had been arcing from the conductor to the conduit. A hole had been burned entirely through the conduit at this point, which was directly under the motor and could not be seen until the conduit was removed from the floor. When the lines were moved during the first inspection as mentioned, it so happened that the bare part of the grounded wire was moved away from the conduit, which accounted for the mysterious way the trouble was cleared at the first trial. It is supposed that after staying in that position for a few hours, it had again moved by jarring caused by the slight vibration of the motor. Upon inspecting the conduit, it was found that water occasionally splashed over from the open jackets of a small vertical compressor near-by and had found its way into the conduit through the end fitting near the motor, which was so located as to allow of that happening. This trouble was overcome by placing an elbow on the conduit so as to point the end fitting horizontally, as shown at *B*. When testing for grounds in conduits, both ends of wires should be disconnected and tests made before moving wires.



MOTOR AND CONTROLLER INSTALLATION

Inquiries of General Interest

Equalizing Cutoff of Single-Valve Engine—How can the cutoff of a single-valve automatic engine be made the same for each end of the cylinder? J. C.

The cutoff can be equalized for any particular load by adjusting the length of the valve rod, and for most valve gears thus adjusted, the cutoff will be practically equal for all loads.

Exhaust Lap—What is meant by "exhaust lap"? A. C.

The "lap" of a valve is the distance the valve overlaps its port when the valve is in the middle of its travel. Exhaust lap is the lap of an exhaust valve. In a "D" slide valve "exhaust lap" is sometimes defined as the distance between the exhaust edge of the valve and the near edge of the steam port when the valve is in its mid-position.

Chattering of Spring-Loaded Safety Valve—What causes a spring-loaded safety valve to chatter or rumble on its seat, and how can it be remedied? H. H.

Chattering or rumbling occurs when the pressure is just enough to balance the valve, but not enough to hold the valve clear of the seat. The chattering or rumbling will be of duration for less time by adjusting the blow-down ring for greater blow-down.

Greatest Expansion at Temperature of Freezing—When water pipes are burst by freezing, at what temperature does the rupture occur? T. P. M.

Rupture usually occurs while the water is passing to the solid state or when the temperature has been returned to the freezing point, which for quiet water at atmospheric pressure is 32 deg. F. and for higher pressures is about 0.0135 deg. F. higher for each additional atmosphere of pressure. During the freezing process the volume becomes about 8½ per cent. greater than water at the same temperature, or the volume may increase a slightly less amount when the original water has been freed from air by boiling. After ice has formed, a reduction of its temperature causes contraction, and reheating to the freezing temperature causes expansion back to the initial ice volume, and the latter may cause rupture of a pipe from local accumulation of the expansion of volume.

Best Thickness of Fire for Forcing Boiler—Can a boiler be forced hardest by carrying a thick fire or a thin one? L. B. R.

The thickness of fire with which a boiler can be forced hardest depends on the denseness of the fuel bed and the draft available. The greatest heat will result from the thickest fuel bed for which the draft is sufficient to supply air necessary for complete combustion, and the greatest absorption of heat or forcing of the boiler will occur when the air supply is not in excess of 1½ to 2 times the theoretical requirement for perfect combustion. More air becomes a vehicle of heat wasted in the chimney gases. Hence the thickness of fire that is most advantageous for forcing a boiler with a given draft cannot be predicted without recourse to trial or analysis of results obtained with given sets of conditions. Under ordinary conditions of draft, fuel and grate area, the greatest forcing can be accomplished with fires carried 3 to 6 in. in thickness.

Pump Fails To Empty Receiver—The feed pump of a pump and receiver apparently in good working order fails to operate at sufficient speed to keep down the water level in the receiver. How can the pump be made to run faster? N. S.

If the pump is in good working order, it may be that it is prevented from operating at a higher speed by excessive back pressure on the discharge or on the exhaust. To ascertain whether the trouble is with the discharge pipe it should be disconnected, and if the pump then runs at a good speed, the trouble comes from back pressure that may be caused by stoppage, excessive pipe friction or attempting to discharge against excessive head pressure. Putting a bleeder connection in the foot of the steam exhaust pipe will show whether the trouble is not due to back pressure of the exhaust. Such a drip always should be employed and left open so there will be no accumulation of condensation to cause back pressure. If the pump and connections are suitable for obtaining normal speed when the float-operated valve is held open, then if it will not work fast enough when operated by the float-controlled valve it may be assumed that the float is set too high or is otherwise prevented from opening the float-controlled steam-supply valve.

Size of Conductors for a Direct-Current Motor—How can the size of the conductors be determined for a 25-hp. 220-volt motor, full-load current 92 amp.? The motor is located 325 ft. from the generator. J. S.

The size of conductors for a two-wire circuit may be found by the formula,

$$\textit{Circular mils} = \frac{21.4ID}{E_d}$$

where I = the current in amperes, D = the length of the circuit one way in feet, and E_d = the volts drop in the line. The volts drop should not be allowed to exceed 5 per cent. For distances under 500 ft. 3 per cent. is a better practice. As 3 per cent. of 220 volts is 6.6, then,

$$\textit{Circular mils} = \frac{21.4 \times 92 \times 325}{6.6} = 97{,}000$$

The nearest larger standard size is a No. 0, B. & S. conductor. This is also the smallest size that can be used in this case, since the National Board of Fire Underwriters' Code specifies that for direct-current motors the circuit capacity must exceed the normal rating of the motor in amperes by 25 per cent. A No. 0 rubber-covered conductor is rated at 125 amp., therefore it has ample capacity to meet the code requirements for a motor rated normally at 92 amperes.

Boiler Horsepower and Coal Required to Heat Water—With evaporative economy under actual conditions of 7 lb. of water per pound of coal and steam at 90 lb. boiler pressure, what quantity of steam and of coal would be required to heat 22,000 gal. of water from 40 deg. F. to 160 deg. F. and what boiler horsepower would be required to heat the water in 10 hours? H. S.

Each pound of water would receive 160 — 40 = 120 B.t.u., and as 22,000 gal. of water would weigh 22,000 × 8⅓ = 183,333 lb., the water would receive 183,333 × 120 = 21,999,960 B.t.u. A pound of steam at 90 lb. boiler pressure contains 1187.2 B.t.u. above 32 deg. F., and when condensed and cooled to 160 deg. F., or 128 deg. above 32 deg. F., each pound would part with 1187.2 — 128 = 1059.2 B.t.u. and under the conditions raising the temperature of the water would require 21,999,960 ÷ 1059.2 = 20,770 lb. of steam. With a boiler economy of 7 lb. of water evaporated per pound of coal, this would require 2967 lb. of coal. A boiler horsepower is equivalent to the evaporation of 34½ lb. of water from and at 212 deg. or 33,479 B.t.u. per hour, and as the heat transmitted to the water would amount to 21,999,960 ÷ 10 = 2,199,996 B.t.u. per hour, the expenditure of steam for heating the water would be at the rate of 65.71 boiler horsepower. The estimates given do not include any allowances for heat lost by radiation from the surfaces of the water heater or the steam-supply pipe.

How Fuel May Be Saved

Two papers presented before the Providence Engineering Society, one by Prof. William H. Kenerson, of Brown University, and the other by Henry W. Ballou, of Jencks & Ballou, consulting engineers, discuss means for the alleviation of the present serious fuel situation and the prevention of waste in the use of steam.

THE Providence Engineering Society held one of its most successful fuel-conservation meetings, Wednesday, Feb. 13, at its headquarters, 29 Waterman St. The meeting was under the direction of the Power Section and was presided over by Warren B. Lewis, of Providence. The first paper, "The Fuel Situation as It Confronts New England," by Prof. William H. Kenerson, of Brown University, Providence, and a paper on "The Abuse of Steam," by four local engineers, read by Henry W. Ballou, follow:

THE FUEL SITUATION AS IT CONFRONTS NEW ENGLAND

Two-thirds of the coal mined in this country is used for generating steam, and of this it is probable that 10 per cent., at least, can be saved. Instead of a shortage of 50,000,000 tons of coal this year, it is likely that there might have been an actual excess over requirements if the preventable wastes had been eliminated. The large public utilities and some of the more progressive manufactures have long since carefully studied and met the situation, but to many users fuel has been such a relatively small item in the total cost of production that the desirability of saving in this direction has not occurred to them. So long as the wheels go round and the plant is comfortably heated, and coal can be easily obtained when wanted, there are too many things of greater immediate importance to claim attention. Now it is not only a desirable economy but a patriotic duty to conserve coal. It has been my good fortune to know a considerable number of the men who immediately control the coal pile, and I know that many are well informed and desirous of getting the most out of fuel. For example, the National Association of Stationary Engineers conducts educational lectures by experts. The burning of coal is a complex chemical problem, and it is no more reasonable to equip a man with a nicked shovel and a woolen cap, which he can use as a pad to hold a hot slice bar, and then expect him to get the best results out of the fireroom, than it would be to turn a chemist loose in a dye works, without balance and graduate, and expect him to get uniform and satisfactory results. And so you see that it is very necessary that we educate the man who hires the man who shovels the coal. He must know what is involved in the burning of coal and that the knowledge of his fireman cannot be utilized unless he is given some facilities which will help him to determine the conditions of his plant and some expert advice from time to time in solving problems as they arise.

In principle, however, the burning of coal is a simple matter. All that is necessary is to thoroughly mix the proper proportions of fuel and air and maintain the whole, including the gases evolved, at such a temperature that the chemical action resulting will be accompanied by the maximum evolution of heat. Then all that remains is to transfer as much of the heat as possible into the water in the boiler. The manufacture of pig iron is just as simple. All that is necessary is to mix the right proportion of iron ore, coke and limestone together, maintain a proper temperature by supplying air to the burning coke and draw off the iron, slag and gases from the blast furnace. But in the latter case the ingredients are carefully weighed and the resulting product is analyzed, all under the eye of an expert chemist, while in the boiler room reliance is often placed on more or less shrewd guessing and no fault is found unless the steam pressure drops. If the guess is wrong and too much air is used, a lot of heat is lost. If the guess is wrong and too little air is used, still more heat is lost. In either case the loss can be made up by simply shoveling in more coal, and nobody knows the difference and nobody cares. Every steam plant needs certain facilities for the determination of facts, together with intelligent supervision. Please do not understand by this that I advocate elaborate plant tests or analyses of fuel at this time. At present we will not question a lump of coal regarding its pedigree if it chances to come our way nor condemn it if it does not contain 14,500 B.t.u. per pound. We are overjoyed to get any kind of coal. Certainly in many cases a complete plant test would be a waste of time and of money. But to deprive the boiler room of measuring devices which show what is going on is as absurd as it would be to deprive the merchant and manufacturer of the yard stick, quart measure or set of scales. The boiler room should at least be provided with means for measuring water and weighing coal, and in addition it would usually be well to provide means for analyzing flue gases. Large sums of money are spent in the boiler and engine rooms and it is as essential that some system of accounting be installed as in any other part of the plant. Incidentally, this makes possible a bonus system based on fuel saved, which in many cases has worked out well. Entirely apart from such a system, however, the men who run steam plants will, in nearly all cases, welcome the opportunity to know the facts that they may better the conditions. Although I have studied many steam plants, I have yet to meet a man in charge who was in any way antagonistic. In most cases they are eager to help in improving conditions. It remains for the manufacturers to capitalize that interest by assisting them with measuring appliances, competent advice and supervision. The return in dollars and cents would be well worth while, and at the same time the present coal crisis would be relieved in the most sensible and logical way.

There is one other way in which many plants could save fuel. Power can be produced in the large central stations far more cheaply than in some small isolated plants. Where there is relatively little use for exhaust steam either for heating purposes or in the processes, coal can be saved by purchasing the power.

THE ABUSE OF STEAM

The aim of this paper is to contribute to the current public discussion on the conservation of coal. It is an endeavor to combine and set forth some of the views of four local engineers who have had experience with the more popular methods of wasting steam in Rhode Island.

There is today within fifty miles of Providence an industry employing 5000 people, which is the last word in systematic scientific management. Its prime movers consist of no less than six small noncondensing engines. For half of the year nearly all the exhaust steam belches to the atmosphere; for the other half a large part is used for heating. The hot drip from the heating system, instead of being returned to the boiler, flows to the sewer, while the annual bill for the feed water amounts to several thousand dollars. There are literally hundreds of similarly flagrant cases.

What the typical Rhode Island manufacturer needs to help him conserve coal is not information about the refinements of the economic use of steam, but ceaseless reiteration of the simplest platitudes about steam. Platitudes as simple as this:

If steam can be seen anywhere out of doors, coal is being wasted.

Another platitude would be:

Are your steam traps and valves leaking coal all of the time? Do you have periodic inspection and reports as to their condition?

These platitudes are ridiculously elementary, but it is doubtful if one plant out of fifty in Rhode Island has any periodic inspection and reports on these vital matters. For illustration, about a year ago the owner of a new plant using central-station electric power complained that his heating system took too much steam and that his boiler plant was not of sufficient capacity. On investigation it was found that the otherwise frozen ground was soft and moist for a considerable distance around a certain cistern. The bypass on a steam trap serving the sprinkler tank had been carelessly left open, and live steam to the tune of several tons of coal per day had been wasting through the trap into the cistern for several months. This is typical Rhode Island cause of deficient boiler capacity.

Steam Traps—Hundreds of cases come under observation where steam traps are either leaking or are bypassed and where the leakage is a source of direct waste. The discharge from traps is frequently connected directly to the sewer or to mill trenches where leakage is invisible, and waste may go on for months and even years undetected. This subject of leaky traps is a long story, but therein lies a great possibility. Nearly every steam plant has steam traps, and sometimes there are hundreds of steam traps in a single manufactory. Yet it is probable that not one plant in ten has its traps so equipped and connected that they can be readily tested for leakage. It is the opinion of a number of engineers that of all the steam traps in Rhode Island today, probably over 75 per cent. are either leaking, are bypassed or are in some way failing to serve their purpose purely for want of regular supervision.

Lax Operating Conditions—There is a large finishing plant in which, a few years ago, an engineer was "turned loose." Within a few months the load on the boilers was reduced fully 1000 boiler horsepower with practically no expense for new equipment, but simply by stopping gross leakage and waste. The most obviously needful changes were often secured with difficulty or secured only in part. In one department there were three sets of large can driers, each set being served by a 2-in. live-steam pipe and a 6-in. exhaust-steam pipe. Steam was kept turned on in both pipes at the same time, despite repeated protests to the manager, the master mechanic and the chief engineer. Of course the live steam was immediately reduced to exhaust-steam pressure, to the end that large quantities of steam went to waste through the back-pressure valve in a remote part of the low-pressure piping system without the slightest advantage to the driers. This is an excellent illustration of the objections to having high- and low-pressure connections to any one piece of apparatus.

This same plant had a large air compressor driven by a cross-compound Corliss engine. It was desired to carry a nearly constant pressure in the compressed-air receivers, and to accomplish this the engine was throttled by hand, running probably 95 per cent. of the time at a speed below which the valves would cut off automatically; in other words, taking steam the full stroke. This engine was equipped with a surface condenser which was not in operation, the engine exhausting directly to the atmosphere. A test was made of the engine as found running, and again when operating condensing and with the valves cutting off properly. It was found that the saving due to operating the outfit as intended by the makers was in excess of 125 boiler horsepower.

Blowoff Valves—Probably not one steam boiler out of a hundred in Rhode Island has the boiler blowoff valves so arranged that they may be readily tested for leaks. Moreover, it is fashionable to submerge the end of the blowoff pipe in some river or brook so that no offensive steam cloud caused by leakage will be perceptible. The blowoff platitude would be as follows:

Are the blowoff valves so connected that they may be readily tested every day?

Pipe Covering—Pipe covering is almost an axiom of steam economy, yet there is no systematic periodic inspection and recorded report on the condition of this most thrifty means of saving coal. It is a popular custom not to cover the flanges because of the inconvenience when a joint leaks.

Excessive Back Pressure on Engines—Where steam is used for heating and drying purposes, it is often economical to operate engines and other prime movers against back pressures. Under these conditions every effort should be made to have this back pressure as low as possible. In one instance, where a single back-pressure gage was in use, it was stated that 1 lb. back pressure was all that was required. But the gage in use and which indicated a pressure of 1 lb. was found to be nearly 4 lb. in error due to faulty piping, and the back pressure was in consequence nearly 5 lb. The platitude in this case would be:

Test the pressures periodically.

In many cases the back pressure has been reduced owing to a more efficient circulation of steam by vacuum heating systems or other means. Plants running condensing can frequently obtain a better vacuum by eliminating air leaks, etc. It is not unusual to find a poor vacuum caused by insufficient condensing water which latter is caused by obstructions in the piping such as leaves and accumulations of foreign matter.

Back Pressure and Reducing Valves—At least four cases have been observed by one engineer where live steam was blowing directly to the atmosphere in large quantities through the low-pressure steam system. These were in the case of a supposedly insufficient supply of exhaust steam, where live steam was being admitted to make up the supposed deficiency. At the time the live steam was being admitted through a reducing-pressure valve or by hand control, the back-pressure valve was partly open, allowing the escape of steam direct to the atmosphere. The remedy is to install properly sensitive back-pressure and reducing-pressure valves so arranged and set as to pressures that it will be impossible for such waste to occur.

Heating Systems—As a general statement it can be said that little or no attention is paid to securing economical operation of heating systems for buildings. Many plants operating noncondensing engines have a surplus of exhaust steam available for heating at all times when the prime movers are running. Under these conditions this steam is likely to be carelessly used, there being a feeling that because it is exhaust steam and there appears to be no other use for it, it is not necessary to use it economically, the result oftentimes being that radiation is not properly trapped and that various drains and bleeders discharge directly to the sewer. Under these circumstances waste of live steam occurs at night and on holidays, at such times as the heating system must be operated with live steam, which in this climate in an ordinary manufacturing plant is a considerable number of hours yearly. Obviously, all open ends become sources of waste when live steam is in use.

Exhaust steam, where available, can frequently be substituted for live steam in heating coils with slight changes in the equipment.

In some cases it has been found possible to extract a certain amount of steam from a compound condensing engine or turbine, such steam first performing a certain amount of mechanical work and then giving up its latent heat (amounting to 90 per cent. of the total heat) to the heating system. A specific instance may be noted where in a cotton-mill plant, the steam which passes through one of the turbines is used in the heating system during the winter months, the unit being operated condensing in the summer months. This is a change made during the present winter which has resulted in a reduction of the load on the boiler plant amounting to more than 200 horsepower.

Hotel-heating systems are as a rule very wasteful, because there is a great tendency toward overheating. Many mills, office buildings, etc., are overheated during most of the winter months. Automatic temperature regulation is in many cases a desirable and profitable adjunct to a heating system, for it prevents overheating.

Some of the older vacuum heating systems are wasteful in that considerable quantities of water are required at the vacuum pump to assist in maintaining a vacuum. This condition is frequently caused by improper automatic expansion valves on the return ends of radiators, in many cases it having been found that the interiors of the valves have been entirely removed, allowing the steam to be pulled through into the return line. Several cases have been observed where large quantities of water were being injected into the vacuum pump and delivered by the pump to an open heater or receiver, and from there overflowing (in the form of hot water) to the sewer.

Leaks—Leaks in pipe joints and flanges are a source of waste larger than is sometimes supposed. The cumulative effect of a wee jet of steam moving perhaps a mile a minute during 24 hours a day is considerable.

Most plants keep their piping systems fairly tight where the pipes are in plain view; but leaky joints on hidden pipes, leaky valves on connections between live and exhaust systems and on drains, etc., are common. It has been found helpful in large plants having many piping connections, to go through the plant late at night when everything is quiet (both out of doors and inside), at which time it is easier to detect the sound of escaping or leaking steam.

Large plants should be equipped with valve reseating tools and should use them whenever necessary to maintain all steam valves in proper condition. This is another matter that should have systematic attention.

Heating of Water—It is quite common in plants using large quantities of hot water to find this water being heated by live steam, while at the same time exhaust steam is being wasted to the atmosphere. This matter needs little comment as it is obvious that great economies can be effected by using exhaust steam for this purpose.

Boiling with Live Steam—In cloth-finishing plants and dyehouses there are many processes, the nature of which makes it necessary to boil large tubs of water with direct steam and maintain them at the boiling point sometimes for hours. Large wastes can occur in this operation, because the amount of steam that can be turned into apparatus of this sort is limited only by the sizes of pipe connections thereto. It is evident that the temperature cannot be increased after the liquid reaches the boiling point. This is a difficult matter to control, as the men handling such apparatus are usually not in the least interested in where the steam comes from or in what it costs.

Automatic temperature regulation can be applied to some work of this character under some conditions, but the sovereign remedy is systematic, skilled oversight and eternal vigilance.

Insufficient Boiler Capacity—Another instance of the typical Rhode Island cause of insufficient boiler capacity may not be irrelevant. The management of a thriving manufactory suddenly concluded that its steam supply was inadequate. It was immediately realized that two new boilers and a new chimney and appurtenances were needed, *and in a hurry*. (Intense hurry is apt to be one of the most distressing symptoms of this disease.) It is the usual custom in such cases to ask the gentlemen who sell boilers and other things to supply the engineering. They do engineering free of charge. But in this instance the management called in an engineer. Instead of installing two new boilers, he shut down one of the old ones. At the end of the next year, during which the business had increased by some millions of yards of cloth, the cost of coal consumed had decreased $8000. This saving was attained by stopping the waste of steam in the dyehouse and by using exhaust steam.

Exhaust steam was used to preheat large quantities of water, instead of putting cold water into dye tubs and bringing it to a boil with live steam as was done previously.

Exhaust Steam—There is, on the part of owners and managers, a universal prejudice against exhaust steam. This prejudice also extends to superintendents and foremen, and it becomes virulent with the workmen. They all know that high-pressure steam will make more commotion and racket than exhaust steam. They know that high-pressure steam will make water boil harder. Most manufacturers are confident that there is some magic property in live steam that is lacking in exhaust steam, even at the same pressure; their head dyers tell them so.

A large part of the failure of some exhaust-steam systems is attributable to a feeling that exhaust steam is cheap—doesn't cost anything—and may therefore be wasted with impunity.

A perpetual campaign of education, remonstrance and expostulation is necessary to prevent the waste of both live and exhaust steam in dyehouses and finishing plants. In the previously mentioned plant where the coal bill was reduced $8000 in a year of increasing business, it is safe to say that the gain would have all been lost in the following year if previous conditions of oversight and management had been resumed.

Platitudes for exhaust steam should be about as follows:

Nine-tenths of the coal used in making steam goes into latent heat.

In making steam nine-tenths of the coal is used before we get an ounce of steam pressure.

When you waste exhaust steam, you waste nine-tenths of the coal used in making live steam.

There are many processes where, with slight changes in the method of drainage, etc., exhaust steam may be used in place of live steam. This is particularly true in cloth-finishing plants, paper mills, rubber works and similar industries, where large quantities of materials have to be dried.

One of the most prolific sources of waste is in the throwing away of the condensed steam in the form of hot or warm water. It should be the aim of every manager to see that no heat is lost to the air or to the sewer which may be recovered.

Enemies Within

It is unfortunate that there can be no powerful government or great industry without its traitors. Often such enemies are fanatics who believe they are right while all others are wrong. The anarchist who plants a bomb to correct a seeming injustice risks his neck and is an honest gentleman compared to that Judas in the coal industry who today is allowing the shipment of dirty coal, and accepting record prices for a product he couldn't possibly sell in normal times.

"That's strong language," you say; and I reply, "It isn't strong enough to fit the case." Furthermore, let it be understood I wouldn't make such an accusation if I hadn't seen with my own eyes many times in many places instances of such a reprehensible practice. Yesterday I saw 60 tons of coal that cost a lot of money that couldn't even be burned without being mixed with real coal of decent quality.

The dishonest clerk who short-changes his customer is a thief, but he hurts only a few people and harms himself most. Here is what the dishonest coal shipper does today:

He is damning an industry that has developed through the exercise of greater individual courage and the endurance of more personal hardship than any other important business.

He is causing the finger of public condemnation to be pointed at honest, conscientious coal operators who have spent a lifetime in the organization and development of reputable mining companies.

He is wilfully and certainly bringing about a situation that can have no other outcome than to deprive efficient mining men of control of their own business, and to hasten government direction of mining, if not Federal ownership.

However, these are only a few of the little things. Here is something more serious:

The very existence of this United States depends on our overthrowing German autocracy. The weak link in our entire war program is transportation. This deficiency in the last three weeks has caused our nation a billion-dollar loss through suspended effort.

Here is what the dishonest coal shipper accomplishes.

The railroads of the United States haul about 1800 million tons of freight yearly; approximately 35 per cent. of this freight is coal. Some coal is sold locally and considerable is used at the mines. Assuming that 630 million tons will be shipped over the railroads this year, it will require 12,600,000 fifty-ton cars to move this output.

Nine per cent. of ash is a normal quantity for American coal. If numerous recent investigations are at all accurate, there is at least 9 per cent. additional adulteration in the coal now being shipped in America. Coal carrying 18 per cent. refuse has but 63 per cent. of the fuel value of coal carrying 6 per cent. ash and requires the transportation of 37 per cent. more coal than is necessary. In certain localities the transportation facilities, due to dirty coal, are being taxed as much as 35 per cent. above normal requirements.

With coal carrying 6 per cent. ash, eight boilers are required to generate 300,000 lb. of steam per hour. With 20 per cent. ash, 19 boilers are required. A certain tonnage of coal running 6 per cent. in ash requires 11 cars to transport it; coal having the same fuel value, but running 20 per cent. ash, requires 17 cars to move it.

For every additional 1 per cent. of impurities in the nation's annual coal production the railroads must haul more than five million tons of useless waste. Coal adulteration means more boilers, more firemen, increased fuel demand and more ash handlers. It is further true that as the percentage of ash in coal increases, the percentage of combustible matter lost in the ashes increases.

It is physically impossible to mine and market coal that contains no noncombustible matter, but when the impurities in our total production average more than 10 per cent., a despicable crime is being perpetrated. The coal industry must rid itself of the pirates that would destroy it, and it is urgent that effective action be taken at once.—*Floyd W. Parsons in Coal Age.*

Why Support the A. A. E.?

The following is from a circular issued by the Committee on Ethics and Coöperation, American Association of Engineers, Isham Randolph, chairman, consulting engineer; W. H. Finley, chief engineer, C. & N. W. Ry.; F. H. Newell, head of School of Civil Engineering, University of Illinois.

A question often asked when the A. A. E. is under discussion is "What is the need of another national society of engineers?" The answer is it is because we are awakening to the fact that the engineers are not occupying their full position of usefulness. The curious anomaly exists that although the victories of war and peace are those of the engineer, yet in most of these the engineer is occupying a secondary place; because of this fact he is unable individually or collectively to utilize his ability to the largest good of mankind. For the last ten years this has been discussed in a more or less abstract manner. Morris L. Cooke in 1908 called attention to the fact that while other professions and lines of business have awakened to the need of definite action, the engineers have been singularly conservative. Dr. Talcott Williams has called attention to the fact that the profession which gives "this age in the various works and achievements of engineers its crowning difference from other ages has less weight in public affairs and on public opinion from any other." "Modern life pays little attention to the word of the engineer." "The engineer will never stand where he should in the state until he discharges his duty at this point (of coöperation and information)."

These quotations taken from among scores that might be used, indicate a condition which, while widely appreciated, has not yet been definitely entered upon by any engineering organization in the same way in which the A. A. E. is acting. Unlike other societies its main object is not mainly that of meeting to discuss technical papers, but rather, not neglecting these, to concentrate on the human matters—the things which affect the engineer as a man and citizen as well as an engineer. It goes into employment because it is the foundation for the success of the individual. Other societies have neglected this fundamental point or at least have given it merely perfunctory attention. The American Association believes in doing what other professional and business organizations are doing for the mutual advancement and protection of the highly trained man from the undermining influence by the unskilled or incompetent. It goes into publicity, advertising if you please, not for the benefit of the individual but of all engineers, because it believes that engineers as a whole will be benefited to the extent that the public knows about the work already performed or of the position to be achieved, which can be realized when the public really understands what can be gained in greater health, comfort and prosperity.

It goes into politics, not the partisan kind, but into the science or practice of the original meaning of the word, that of helping to direct affairs of public policy, of the greatest good to the greatest number. It believes that every intelligent, educated man or engineer educated largely at public expense, should individually and collectively devote a part of his time to the affairs of the community, especially those which touch the practice of engineering. Ours is a political government and every citizen is vitally interested in politics and every engineer who does not take an intelligent interest in public questions and array himself in the cause that appeals to his reason and sense of right, fails in duty to himself, to his community and to his country. Engineers have fallen far short of their duties and privileges in this respect.

Why is it that engineers have done so little in this direction? It is because the older societies established precedents that have hampered growth in public affairs. They were early impressed with the danger of being considered unprofessional or falling into the category of commercialism. They have prided themselves on keeping away from the very subjects that are most vital to the majority of members of the engineering societies. There is no class of educated people more bound to traditions in this regard than the engineer, nor none who have made slower progress toward efficiency in their own organizations.

Illuminating Engineers Hold Special Meeting

On Thursday evening, Feb. 14, 1918, in the Engineering Societies Building, New York City, the Illuminating Engineers held a special meeting for the purpose of discussing the saving of coal by lighting curtailment. The meeting was formally opened with a short address by G. H. Stickney, president of the society, after which Preston S. Millar, chairman of the Committee on War Service of the Illuminating Engineers, presented his paper on "Lighting Curtailment." An abstract of this paper will appear in an early issue of *Power.*

The discussion was opened by J. W. Lieb, chairman of the National Committee on Gas and Electric Service, of the Council of National Defense. During Mr. Lieb's address he read a resolution, filed with Dr. Harry A. Garfield, National Fuel Administrator, setting forth what his committee believes to be the attitude of the electric-light and power companies of the country on the question of sign lighting in its relation to national fuel conservation. The resolution minus the whereases read as follows:

Resolved, that the public-utility companies throughout the United States through their organization, the National Committee on Gas and Electric Service, of the Council of National Defense, representing the gas companies—manufactured and artificial—the electric-light and power companies, the water-works companies and the central steam-heating companies throughout the country, pledge their hearty support and coöperation to the national authorities in carrying out any plan or regulation for the saving of fuel, gas, oil or electricity which the national authorities in the public interest may consider it necessary to adopt as a war measure.

Morton G. Lloyd, of the National Bureau of Standards, Washington, D. C., called attention to the tremendous waste of fuel due to overheating our buildings, residences being the most uneconomical and industrial plants almost as bad in their methods of burning coal. Mr. Lloyd took the opportunity to criticize the coal operators of the country for the poor quality of coal that they have been supplying, pointing out that there might be some excuse for doing this if the mines could not produce sufficient quantity, but if the operators' claim, that the coal shortage is due entirely to lack of transportation, is true, then there is no excuse for shipping the extremely low grades about the country.

Many others took part in the discussion, and the general opinion expressed was that every effort possible should be made to save coal by the curtailment of all unnecessary lighting, but that the amount of fuel that could be saved by the elimination of waste in other directions was so great that the possible saving by the curtailment of light becomes almost insignificant in comparison.

Probably one of the most disappointing features to many who attended the meeting was the absence of representatives from the national, state and municipal fuel administrations. Representatvies from each of these bodies had been invited to take part in the discussion, but for some reason failed to avail themselves of this opportunity.

The address of C. M. Griffin should be 114 First St., Newburgh, N. Y., instead of 114 Spruce St., as given in the article on page 183 of *Power* for Feb. 5, descriptive of his condenser-tube cleaner.

Electricity To Solve the Fuel and Transportation Problems

By E. W. Rice, Jr.

President, General Electric Co. and the A. I. E. E.

An address delivered at the opening session of the midwinter convention of the American Institute of Electrical Engineers, held in New York City, Feb. 15 and 16, 1918. The speaker sets forth the tremendous saving in fuel that can be accomplished by a universal electrification of our steam railways, also that at least 50 per cent. increase in available capacity of existing tracks can be obtained by substituting electricity for steam in the operation of the railroads in this country.

MEMBERS of the electrical profession and industry have reason to be pleased with the contributions which they have made for the benefit of the world. While we are glad to think that our science and our industry are fundamentally devoted to the products and conditions of peace, we realize that in the electric light, searchlights, the X ray, telephones, telegraph, wireless apparatus, electric motors, etc., electricity plays an important part in the grim business of war.

We are in the midst of an extraordinary coal famine, due to causes which it is perhaps undesirable for us to attempt to outline. However, I would like to point out how much worse the situation might have been were it not for the contributions of the electrical engineers; and also how much better our condition might have been if our contributions had been more extensively utilized.

Electricity Increased Coal Production

Suppose we assume that the present serious situation is due to a lack of production of coal. It is comforting to consider to what extent conditions surrounding such production have been improved and how the output of our coal mines had already been increased by the use of electrical devices in connection with coal mining—such for example as the electric light, electric coal cutters, electric drills and electric mining and hauling locomotives. I have no figures before me, but I think it is a fair assumption that the output of coal mines should have been increased at least 25 per cent. on the average by the employment of such electrical devices. If this estimate were cut down to 10 per cent., it would still leave a possible increase in the coal produced of something like 50,000,000 tons during the past year.

If, on the other hand, our situation is not due to a shortage in the production of coal, but rather to the failure of the distributive agencies of the country, which is more probable, it is interesting to see how this difficulty would have been largely removed if the railroads of the country were operated by electricity instead of steam.

Where electricity has been substituted for steam in the operation of railroads, fully 50 per cent. increase in available capacity of existing tracks and other facilities has been demonstrated. This increased capacity has been due to a variety of causes, but largely to the increased reliability and capacity, under all conditions of service, of electric locomotives, thus permitting a speeding up of train schedules by some 25 per cent., under average conditions. Of course, under the paralyzing conditions which prevail in extremely cold weather, when the steam locomotives practically go out of business, the electric locomotives make an even better showing. It is well known that extreme cold (aside from the physical condition of the traffic rail) does not hinder the operation of the electric locomotive, but actually increases its hauling capacity. At a time when the steam locomotive is using up all its energy by radiation from its boiler and engine into the atmosphere, with the result that practically no useful power is available to move the train, the electric locomotive is operating under its most efficient conditions and may even work at a greater load than in warm weather. It may therefore be said that cold weather offers no terrors to an electrified road, but on the contrary it is a stimulant to better performance instead of a cause of prostration and paralysis.

But this is not all. It is estimated that something like 150,000,000 tons of coal was consumed by the railroads in 1917. Now we know from the results obtained from such electrical operation of railroads as we already have in this country that it would be possible to save at least two-thirds of this coal if electric locomotives were substituted for the present steam locomotives. On this basis there would be a saving of over 100,000,000 tons of coal in one year. This is an amount three times as large as the total coal exported from the United States during 1917.

Coal Restricts Capacity of Railroads

The carrying capacity of our steam roads is also seriously restricted by the movement of coal required for haulage of the trains themselves. It is estimated that fully 10 per cent. of the total ton-mileage movement behind the engine drawbar is made up of company coal and coal cars, including in this connection the steam-engine tender and its contents. In other words, the useful or revenue-carrying capacity of our steam roads could be increased about 10 per cent. with existing track facilities by eliminating the entire company coal movement.

I have not mentioned the consumption of oil by the railroads, which we are told amounted in 1915 to something like 40,000,000 bbl., nearly 15 per cent. of the total oil produced. This fuel is entirely too valuable to be used in a wasteful manner. It is important for many reasons that such a wonderful fuel as oil should be most economically used, if for no other reason than that it will be needed for the ships of our forthcoming merchant marine, for the tractors that till our fields, and for the motor trucks that serve as feeders to our railways.

The possible use of water power should also be considered in this connection. It is estimated that there is not less than 25,000,000 hp. of water power available in the United States, and if this were developed and could be used in driving our railroads, each horsepower so used would save at least 6 lb. of coal per horsepower-hour now burned under the boilers of our steam locomotives. It is true that this water power is not uniformly distributed in the districts where the railroad requirements are greatest, but the possibilities indicated by the figures are so impressive as to justify careful examination as to the extent to which water power could be so employed and the amount of coal that could be saved by its use. There is no doubt that a very considerable portion of the coal now wastefully used by the railroads could be released to the great and lasting advantage of the country.

Water Power Allowed To Run to Waste

The terrors of these "heatless days" will not have been without benefit if they direct the attention of the people and of our law makers to the frightful waste of two of our country's most valuable assets—our potential water power and our wonderful coal reserves. The first, potential water power, is being largely lost because most of it is allowed to run to waste, undeveloped, unused. The second asset, coal, is wasted for exactly the opposite reason. It is being used but in an extravagant and inefficient manner.

Our waterfalls constitute potential wealth which can be truly conserved only by development and use. Millions of horsepower run to waste every day, which, once harnessed for the benefit of mankind, become a perpetual source of wealth and prosperity.

The amount of coal in our country is enormous, but it is definitely limited. While Providence has blessed us with a princely amount of potential riches in our coal beds, it is known that there is a finite limit to the amount of coal so stored and when this coal is once exhausted, it is gone forever. It is really terrifying to realize that 25 per cent. of the coal that we are digging from the earth each year is burned to operate our railroads under such inefficient conditions that an average of at least 6 lb. of coal is required per horsepower-hour of work performed.

The same quantity of coal burned in a modern central power station would produce an equivalent of three times that amount of power in the motors of an electric locomotive, even including all the losses of generation and transmission from the source of power to the locomotive. Where water power may be utilized, as in our mountainous districts in the West, all the coal used for steam locomotives can be saved. In the Middle and Eastern States, however, water powers are not sufficient and it will be necessary in a universal scheme of electrification that the locomotives be operated from steam-turbine stations; but as I have already stated, the operation of the electrified railroads from steam-turbine stations will result in the saving of two-thirds of the coal now employed for equivalent tonnage movement by steam locomotives.

Electrification Not an Inventor's Dream

It is, therefore, not too much to say that if the roads of the country were now electrified, no breakdown of our coal supply, due to failure of distribution, would exist. What this would mean for the comfort of the people and the vigorous prosecution of the war, I will leave for you to imagine.

Of course this picture, which I have briefly and inadequately sketched, of the great benefits which our country would have received if the roads had been electrified, does not improve our present situation and it may be claimed that any discussion of such a subject at this time is of an academic nature. This point of view is in a sense true, but I think that we can properly take time to consider it because of the effect which it may have upon our future efforts. This picture is not merely an inventor's dream, but is based upon the solid foundation of actual achievement. We have had enough experience upon which to base a fairly accurate determination of the stupendous advantages and savings which will surely follow the general electrification of the railroads; in fact, I think we can demonstrate that there is no other way known to us by which the railroad problem facing the country can be as quickly and as cheaply solved as by electrification.

The solution of the railroad problem would also "kill two birds with one stone" by solving the fuel problem at the same time.

If it is a fact, as has been stated, that the steam railroads of the country have failed to keep pace with the country's productive capacity—the increased output of manufacturing industries, the extension of agriculture and other demands for transportation—it is obvious that if the country is to go ahead, the railroad-transportation problem must be solved and it must be solved at the earliest possible date. It becomes a matter of national importance that the best solution should be reached in the shortest possible time. That solution is best which will give the greatest amount of transportation over existing tracks, in the most reliable manner and, if possible, at the lowest operating cost.

Every Element of Electrification Solved

We electrical engineers would not be justified in being so confident of the benefits of electrification of railroads if every element in the problem had not been solved in a thoroughly practical manner. The electric-generating-power stations, operated either by water or by steam turbines, have reached the highest degree of perfection, efficiency and reliability, while the transmission of electricity over long distances, with reliability, has become a commonplace. Electric locomotives capable of hauling the heaviest trains at the highest speeds, up and down the heaviest grades, have been built and found in practical operation to meet every requirement of an exacting service.

There is, therefore, no element of uncertainty, nothing experimental or problematical, which should cause us to hesitate in pressing our claims upon the attention of the country.

I realize that the task of electrifying all the steam railroads of the country is one of tremendous proportions. It would require under the best of conditions many years to complete, and demand the expenditure of billions of dollars.

The country, however, has clearly outgrown its railway facilities, and it would require, in any event, the expenditure of billions of dollars and many years of time to bring the transportation facilities up to the country's requirements.

It is not necessary that electrification should be universal in order to obtain much of its benefits. It is probable that one of the most serious limitations of our transportation system, at least in so far as the supply of coal is concerned, is to be found in the mountainous districts, and it is precisely in such situations that electrification has demonstrated its greatest value. Electrification of a railroad in a mountainous district will in the worst cases enable double the traffic to be moved over existing tracks and grades.

If a general scheme of electrification were decided upon, the natural procedure would be, therefore, to electrify those portions of the steam railroads which will show the greatest results and give the greatest relief from existing congestion. Electrification of such sections of the steam railroads would have an immediate and beneficial effect upon the entire transportation system of the country, and it is our belief that electrification offers the quickest, best and most efficient solution that is to be obtained.

It may be said that the present is not a propitious time in which to deflect any of the country's money into railroad electrification. I think that in spite of the enormous advantages of which I have spoken, we would be inclined to agree with such a point of view if it were not for the recent unpleasant demonstration of the failure of our railroad-transportation systems to meet the demands placed upon them by the industries, aggravated it is true by the war conditions and also by the unkindness of the weather.

After all, the question for the country to decide is whether we dare to limp along with the present conditions of restricted production, due to limited transportation, at a time when the world demands and expects from us the greatest possible increase in our efficiency and production.

What assurance have we that the present conditions are temporary? And even if they improve, as they will with the coming of warm weather, what are we going to do next winter? Of course, even if we should start electrification at once, we could not have all our railroads electrified by next winter, but we could have a good start, and as Sherman said about the resumption of specie payments, "The way to resume is to resume," so "The way to electrify is to electrify."

College of the City of New York Giving Boiler-Room Course

The College of the City of New York has offered a course in boiler and fuel economy, under Harry Baum, an engineering expert. The course is given at the college on Thursday evenings from 7:30 to 9:18. The first lecture was given Feb. 21, 1918.

The course is intended for such men as building managers and superintendents, operating engineers, firemen, public-school janitors, engineers, library janitors and others who have not had technical training, but who are interested in the subject.

The prerequisites for this course are a knowledge of simple arithmetic, common sense and an interest in the subject. The fee is $7.50, and for city employees $5. The course is under the direction of Frederick B. Robinson, City College, Convent Ave. and 139th St., New York City.

A. I. E. E. Midwinter Convention

The American Institute of Electrical Engineers held its sixth annual midwinter convention in the Engineering Societies Building, New York City, Feb. 15 and 16, 1918. On account of conditions due to the war, the Meetings and Papers Committee with the approval of the board of directors made this convention purely a business meeting, eliminating all entertainment features and excursions, so that instead of the convention occupying three days as in previous years, this season's sessions were curtailed to one and a half days. Four technical sessions were held at which nine papers were presented and discussed. Although, as would be expected, the attendance was smaller at this season's convention than in previous years (280 members and guests registering), it is doubtful if more enthusiasm and interest was ever shown in the meetings.

The first session, Friday morning, was devoted to the subject of "Circuit-Breaker Ratings," President E. W. Rice, Jr., occupying the chair. Mr. Rice addressed the meeting on the solution of the country's fuel and transportation problem by the electrification of our railways. This address appears in this issue, beginning on page 310.

One paper, "Rating and Selection of Oil Circuit-Breakers," by E. M. Hewlett, J. M. Mahoney and G. A. Burnham, was presented at this session. It was read by Mr. Burnham and discussed by Messrs. Hewlett and Mahoney. In this paper the authors discuss the interpretations of the A. I. E. E. Standardization Rules covering the rating of oil circuit-breakers and consider the variable factors involved in the selection of circuit-breakers for various systems. A method is suggested whereby short-circuit characteristics of various systems can be used for determining the proper selection of oil circuit-breakers for average systems. The method does not apply to very large systems or unusual conditions.

In the open discussion on the paper it was made evident that there was a need of some standard for the selection of electrical protective equipment. It was also brought out that, although oil circuit-breakers had been constructed that had ruptured as high as 500,000 kv.-a, there are so many variable conditions in systems on which circuit-breakers are used that it is impossible to give a simple rule covering the selection of circuit-breakers for all cases.

The Friday afternoon session was presided over by Vice-President L. T. Robinson. This session was devoted to the subject of "Meters and Measurements." Four papers were presented. The first, "A New Standard of Current and Potential," by Chester T. Allcutt, was given in abstract by the author. This paper describes a new secondary standard which is proposed as a substitute for the standard cell in certain classes of direct-current measurements. The device consists of a Wheatstone bridge which will balance for but one value of current. Various factors affecting the accuracy and permanence of the device are discussed and a number of curves are given showing the characteristics which have been obtained.

The second paper, "The Thermoelectric Standard Cell," by C. A. Hoxie, was also presented in abstract by the author. It considers a means of obtaining a secondary standard electromotive force by utilizing the voltage of a thermocouple. The standard thermo cell is fundamentally a standard of current, in that it requires a definite value of current to function properly. The operation of the cell consists in balancing the potential across a resistance against the thermoelectric em.f. of the thermocouple. This requires a definite value of current through a filament which is a source of heat for the thermocouple.

"The Character of the Thermal-Storage Demand Meter," by P. M. Lincoln, was read by the author. Following a detailed description of the principle and construction of the thermal-storage demand meter, the author shows wherein it always indicates what may be called "logarithmic average" rather than "arithmetic average" of power consumption, heretofore indicated by practically all demand meters. The inherent faults of the "arithmetic average," or "block interval" meter, are described and examples given demonstrating that the thermal-storage meter alone recognizes the true heating effect that fixes size of equipment and therefore cost that should be assessed against the customer. This paper will be published in abstract in an early issue of *Power*.

During the discussion of this paper the question was raised as to the justification of basing rates upon the maximum demand of the customer, the opinion being expressed that the diversity factor of the load on the system should be taken into consideration. In answer to this question Mr. Lincoln said that the cost of the equipment at the customer's load end of the line justified basing a rate upon the maximum demand of that customer, because the equipment to render service cost practically the same whether the customer used it continuously or for a short period only.

The last paper given at this session, "Measurement of Power Losses in Dielectrics of Three-Conductor High-Tension Cables," by F. M Farmer, was presented in abstract by the author. This paper describes the method used at the Electrical-Testing Laboratories for measuring the dielectric-power losses in 10-ft. samples of three-conductor cables with three-phase potential applied to the cable. The difficulties encountered and the methods employed to overcome them are discussed in considerable detail. Typical results are given in the form of data for two specimens of cable, one having a low power loss in the dielectric and one having a high power loss in the dielectric. The data are also presented in the form of curves.

The interest taken in this session was evidenced by the large attendance and the length of the session, which lasted from 2:30 until after 6 p.m.

Between the Friday afternoon and evening sessions an informal dinner was served at the Cafe Boulevard, Broadway and 41st St., 225 members and their guests attending. The dinner was followed by an inspiring address by President E. W. Rice, Jr., on what this country has accomplished so far toward the prosecution of the war, and the problems that lie ahead of us to win this great conflict. This lecture will appear in an early issue of *Power*.

The Friday evening session was presided over by President E. W. Rice, Jr., and was devoted to a lecture by Dr. A. C. Crehore, on "Some Applications of Electromagnetic Theory to Matter." Dr. Crehore during his address showed how a number of the conclusions were arrived at mathematically as regards the electron theory.

The Saturday morning and last session was called to order by Vice-President B. A. Behrends. This session was devoted to a discussion of "Alternating-Current Commutator Motors." Three papers were presented. "The Polyphase Shunt Motor," by W. C. K. Altes, was read in abstract by the author. "Commutation in Alternating-Current Machinery," by Marius A. C. Latour, the noted French electrical engineer, in the absence of the author was presented by C. O. Mailloux. These two papers are very largely a mathematical discussion on alternating-current commutator motors.

The third paper, "The Secomor—A Kinematic Device Which Imitates the Performance of a Series-Wound Alternating-Current Commutating Motor," by V. Karapetoff, was presented by the author. Mr. Karapetoff had one of his instruments present on which he gave a demonstration of its operation and use. No small amount of attention was taken in this new device to assist in the designing of series-wound polyphase commutating motors, which are beginning to come into quite extensive use at the present time.

Workers for the Shipyards

Because ships are the primary factor in the winning of this war, and because the construction of these ships depends, and will always depend, upon labor, there has been created an organization of workmen known as the United States Shipyard Volunteers, enrolled under the Public Service Reserve. This organization is composed of workmen who are willing to give a good day's work for a good day's pay; workmen who will stand ready, when called upon, to do a particular job for a particular wage in a particular place, and who have enrolled themselves in this organization so that when needed they may be readily reached.

The need of the nation is great. The Shipping Board has the money, the housing of men is being arranged for, the yards are being completed and the materials provided. All that now is lacking is the knowledge of the need that will inspire loyal and efficient mechanics to enroll for service in the yards, though not in a fashion to disrupt the business of the country through the robbing of present industries.

It is urged that mechanics go at once to the nearest enrollment agent of the United States Public Service Reserve of the Labor Department, or to the local enrollment agent of their State Council of Defense, and register themselves as willing to work in the shipyards if needed; then to retain their present positions until called personally for service.

Through the Council of National Defense an appeal has been made to governors, mayors and other prominent officials, to stimulate interest in their communities.

In addition to the card which the volunteer fills out for the Public Service Reserve, he signs the following franked postcard, addressed to Chairman Hurley at Washington:

> Appreciating the Nation's imperative need for skilled workmen to build merchant ships with which to overcome the submarine menace, I request to be enrolled as a member of the United States Shipyard Volunteers of the Public Service Reserve. I realize that the World War will be won or lost in the American shipyards. Every rivet driven is a blow at the Kaiser. Every ship turned out brings America nearer to victory.
>
> It is understood that if I am asked to enter shipyard employment, my compensation shall be at the rate of wage prevailing in such yards.

The button which the workmen receive after enrolling bears this inscription: "U. S. Shipyard Volunteers." A service certificate will be given to all who enroll.

The list following shows the kind of trades most needed in shipbuilding, and a particular appeal is addressed to men in those occupations to enroll in the Reserve: Acetylene and electrical welders; asbestos workers; blacksmiths, anglesmiths, drop-forge men, flange turners, furnace men; boilermakers, riveters, reamers; carpenters, ship carpenters, dock builders; chippers and calkers; electrical workers, electricians, wiremen, crane operators; foundry workers; laborers, all kinds; loftsmen, templet makers, machinists and machine hands, all sorts, helpers; painters, plumbers and pipefitters; sheet-metal workers and coppersmiths; shipfitters; structural iron workers, riveters, erectors, bolters up; other trades, cementers, crane men.

Mobilizing the Educational Institutions

It is estimated that within the next six months 75,000 to 100,000 men will be given intensive training in schools and colleges. With a view to mobilizing the educational institutions of the country and their facilities for such special training, there has been created in the War Department a "Committee on Education and Special Training," associated with which committee will be five civilian educators: Dr. Charles R. Mann, of the Carnegie Foundation for the Advancement of Teaching and the Massachusetts Institute of Technology; Dr. James R. Angell, of Chicago, Dean of the Faculties of the University of Chicago; J. W. Dietz, of Chicago, Director of Education, Western Electric Co., President of the National Association of Corporation Schools; James P. Munroe, of Boston, a member of the Federal Board for Vocational Education (which appointment will include the interests of the trade schools and schools of secondary grade), and Dr. Samuel P. Capen, of Washington, specialist in higher education.

Manhole Heads for Heating Mains

Manholes surrounding fittings in the heating mains, particularly high-pressure steam mains, are one of the greatest sources of heat loss. This heat loss is concentrated in the manhole head which is in direct contact with the pavement.

The damage to pavement, particularly asphalt pavement, is a continual cause of complaint from city highway departments and property owners and a continual source of damage claims and expense. The Underground Construction Committee of the National District Heating Association desires to arrive at a solution of these troubles and has sent out the following questionnaire. Replies should be addressed to H. A. Austin, Chairman, 280 Madison Ave., New York.

A. What class of mains do you operate? High pressure steam? Low pressure steam? Hot water? (Give operating pressure.)

B. What type of manhole do you use? Concrete? Brick? Cast iron sectional?

C. How do you insulate the fittings in your manholes? (Give details.)

D. Do you have trouble with pavement around manhole heads? What kind of pavement? Describe trouble and state inside temperature manhole when closed.

E. What valves, traps, fittings, expansion joints, or specials in manhole?

F. Do you pave around manhole head in special manner? (Give details and sketch.)

G. What have you done to overcome heat losses at manholes?

H. What suggestions have you to offer regarding construction of manholes, such as insulating sidewalks, etc.? (Give details and sketch.)

I. What suggestions have you to offer regarding special insulation of fittings in manhole? (Give details.)

Five Powerless Days Saved Coal

The W. S. Barstow & Co., in their weekly news letter No. 59 give some comparative figures of coal saved as a result of the Fuel Administration order for the closing down of industries from Jan. 18-22 inclusive. The following figures are from seven plants operated by the company:

COMPARATIVE FIGURES ON COAL SAVED FROM JAN. 18 TO 22 INCLUSIVE

Company	Average Coal Consumption for a Like Five-Day Period, Tons	Coal Consumption for the Five-Day Period in Question, Tons	Coal Saved During the Five-Day Period in Question Jan. 18-22 Tons
Binghamton Light, Heat and Power Co	303.40	246.80	56.60
Metropolitan Edison Co	1,240.00	935.00	305.00
New Jersey Power and Light Co	179.90	148.10	31.80
Northwestern Ohio Railway and Power Co	190.42	*207.91	−17.49
Pennsylvania Utilities Co	1,490.00	850.00	640.00
Sandusky Gas and Electric Co	236.50	152.50	84.00
Sayre Electric Co	103.52	97.52	6.00
Totals	3,743.74 —	2,637.83 =	1,105.91

Figures given are in long tons—2,240 lb. * Coal in excess of ordinary consumption used on account of severe storms.

President Wilson Signs Garabed Bill

On Feb. 9 President Wilson signed the so-called Garabed bill. This measure, as explained in the issue of *Power* for Feb. 5, assures to the inventor of the Garabed, or free-energy motor, protection of his rights in the invention for a period of seventeen years, and gives the Government the free use of the device. It also provides for the appointment of a committee of five eminent scientists, before whom the invention is to be demonstrated, to determine whether it is practicable. The inventor, Garabed T. K. Giragossian, of Boston, is now arranging with Secretary Lane for the selection of the committee of scientists. The opinion prevails that these men will be taken from the faculties of such well-known technical institutions as Massachusetts Institute of Technology, Harvard and Tufts. Engineers will await the report of the committee with a considerable degree of expectancy.

In recent discussion of the subject of electrolytic corrosion of steel before the Iron and Steel Institute, it was brought out that, "Water containing carbonic dioxide is electrolytic at adjacent anodic and cathodic areas in a steel surface. These areas may be revealed by use of an indicator of phenolphthalein and potassium ferricyanide. Where iron dissolves, a blue, and at cathodic spots, a pink, reaction is obtained." The quotation is from a letter in London *Engineering*.

Waste of Fuel and the Remedies

At a meeting open to the public, held by N. A. S. E. No. 1, in Fullerton Hall, Art Institute, Chicago, Joseph Harrington, chairman of the Committee on Technical Publicity of the United States Fuel Administration for Illinois, delivered an interesting talk on the "Waste of Fuels and the Remedies."

In his discussion Mr. Harrington had two objects in mind: First, a brief outline for the benefit of nontechnical members present, showing the causes of waste of fuel and the remedies that could be applied thereto in a practical manner; and second, an endeavor to bring out the fact that the stationary engineer, through his control of both steam production and consumption, was handling a necessity of life, and as such should be rated as one of the important cogs in every industrial establishment using power. The technical end of the discussion was intended to show that if the engineer is given adequate assistance in the way of the proper instruments and the necessary moral support, it is possible to save substantial amounts of coal.

Without the aid of certain instruments, Mr. Harrington claimed that it is not feasible to apply measures of economy. In the electrical department switchboard instruments are considered an absolute essential without which a generator would not be started. Voltage can be regulated approximately by the brightness of the lamps, but the method is not to be considered for a moment. It is no more possible, and should no more be countenanced in the boiler room, that the fireman should operate his boiler and judge of the efficiency of the combustion by merely inspecting the fire by eye. While an experienced fireman can approximate the conditions by looking into the furnace, it is impossible for the average man to do so. Instruments are therefore a necessity, and they should be backed up by adequate records.

A record system that does not show the effect of each and every change made by the engineer is useless. Mr. Harrington brought out the point that in undertaking an efficient examination a test should be conducted under operating conditions to show wherein the losses are greatest and division should be made of furnace and boiler losses. With the heat-balance test before him the engineer would then be in a position to locate the loss and apply the remedy. After this the records should show the effect on the plant efficiency of any changes made, and if they fail to do this they are valueless.

Changes should be made one by one in such manner that close records may be kept and the proper credit be given to each change. These records must go to the chief engineer and from him to the plant manager or owner. As the owner is usually nontechnical, the details would neither interest nor enlighten him. The result that the fuel administration is after in this campaign is to reduce the quantity of coal burned to produce a given amount of steam, and unless the changes actually accomplish this, they have not been beneficial. The plant owner, therefore, should be given a data sheet in which this one main significant figure predominates. To get this, two instruments are essential—a coal-weighing device and a water or steam meter. In the larger plants one more step can be taken and that is a regular coal analysis that will permit the engineer to report the number of B.t.u. consumed per thousand pounds of steam from and at 212 deg. This is the ultimate criterion and is the one on which a just comparison can be based.

When the records have been arranged, there is one other matter that must be given attention by the owner. He must consider that the engineer and the engineering department constitute a link in his manufacturing chain that is all-important and without which manufacturing processes cannot be carried on. Instead of considering the power plant in the light of a necessary expense, it must be considered one of the prime factors and be given every support. The engineer himself must be assisted in every possible way in acquiring information about his business; he must be given the tools necessary to efficiently carry on his work, and he must be encouraged in the reporting of results in an intelligent manner so that both he and the owner may profit by the experiences of the past. The plant itself should be put in such shape that operatives can work comfortably and use all the intelligence with which they are endowed. Very high temperatures in the boiler room, dark and dirty surroundings, lack of washing facilities and lack of office space for the engineer, all conduce to indifference and neglect on the part of the men, which in turn results directly in increased fuel costs. One of the most prolific sources of economical combustion is a general toning up and dignifying of the work of handling the power department.

Why a Fire Policy Was Avoided

An application form filled out as a basis for issuing a policy insuring an industrial plant against fire contained the question, "Is steam power, water power, or what other power is used?" This was answered, "Water." The next question was left unanswered, "If gasoline power is used, then describe the location of the engine, gasoline storage tank, spark igniter," etc. Applicants also remitted in payment of a premium based on use of water power only, although a gasoline engine was in auxiliary use in its plant and it was known that this called for a higher rate. The insurance company's representative knew that the engine had been used about three months before and drew attention to the fact that this was not disclosed in the application. The mill, the subject of insurance, burned one night just after the gasoline engine had been shut down. Under these circumstances the Pennsylvania Supreme Court holds in the case of Corbin et al. vs. Millers' Mutual Fire Insurance Co. of Harrisburg, 102 Atlantic Reporter, 425, that the insurance company was not liable for the loss; the statements in the application amounting to a warranty of facts material to the risk, and it being found that notwithstanding the company's representative's previous knowledge concerning the use of a gasoline engine, the company was entitled to assume that such use had been discontinued.

Dog as Power-Plant Adjunct

Where a factory employee was sent on an errand to the basement of a building and was injured by a dog that the engineer of the plant had been permitted by the common employer to keep there, it was decided by the Appellate Term of the New York Supreme Court in the recent case of Barone vs. Brambach Piano Co., 167 New York Supplement, 933, that the accident must be deemed to have been one sustained in the "course of employment," within the purview of the New York Workmen's Compensation Act. The court said:

> There is no doubt that the plaintiff was engaged in performing the duties of his employment at the time he was bitten. The presence of the dog, with the employer's implied knowledge and consent, was one of the physical conditions of the plant under which the defendant required the plaintiff to perform his duties. The mere fact that the direct cause of the injury was animate, rather than inanimate, does not alter the result; nor in this view can I see any force in the suggestion that the dog was not especially kept as a watch dog, or for some similar purpose (though I think the proof showed that it was so employed). The right of the plaintiff to a recovery does not, on any theory of which I am aware, depend upon the comparative usefulness to the employer's business of the immediate cause of the injury.

War-Savings and Thrift Stamps

The sale of War-Savings and Thrift Stamps has been made much easier and missionary work much more effective by the use of the blue return post card, Form WS-138. This card is an order for War-Savings and Thrift Stamps to be delivered at your door C. O. D. The blue card provides the simplest, easiest, safest and least objectionable way of obtaining a pledge to buy stamps and the utilization of the card permits a vast amount of better patriotic campaigning. It is also convenient for agents when ordering supplies.

The card explains its utility to all who can read. It does away with uncertainty, difficulty and delay in securing stamps, for Uncle Sam's letter carriers will fill all blue post card orders in the earliest mail, thus eliminating both bother and risk. The cards can be obtained free in large quantities at almost any post office or bank and from the letter carriers.

METHODS FOR INCREASING THE RECOVERY OF OIL SANDS. By J. O. Lewis. Bureau of Mines, Bulletin No. 148. Petroleum Technology 37.

In its efforts to reduce waste and increase efficiency in oil production, the Bureau of Mines is investigating methods of increasing the recovering from the underground sources of supply which are the foundation of the petroleum industry and the allied industries wholly or partly dependent on it. In the face of a demand that is increasing faster than the production, and that in the consensus of opinion of well-informed authorities is soon likely to outstrip the productive commodity, it is well to consider whether it is not possible to extract more oil from the known sources of supply. It is universally acknowledged that by the usual production methods much oil is left underground, the general opinion being that at least 50 per cent. of the oil in the field remains unrecovered when the field is abandoned as exhausted. The writer believes from his investigations that the average recovery is even less, and if any considerable portion of this oil being left underground could be made available, it would have a tremendously favorable influence on the petroleum industry.

This publication considers the principles involved in increasing recovery and methods of extracting more oil from the oil-bearing formations than by the usual way of producing. These methods are: The use of gas or vacuum pumps in forcing compressed air or gas through the oil-bearing formations, displacing the oil by water, and further utilization of the natural pressures in the oil-bearing formations. Special attention is being given to a process commonly known as the Smith-Dunn for forcing compressed air through oil-bearing formations because it is believed to hold the most promise for the future.

The article is of interest to power-plant men for the reason that it shows that the Bureau is active in attempting to recover the maximum of oils in the oil field. These oils, of course, are not only used for fuel purposes but for lubrication.

SAFE PRACTICES

Bulletins No. 8, 9 and 10, issued by the National Safety Council, Continental and Commercial Bank Building, Chicago, Ill., are just off the press, "being an orderly presentation in loose-leaf form of accident hazards and the best practices for their elimination." No. 8 (pages 85 to 92 inclusive of the series) pertains to "shafting, couplings, pulleys, gearing, etc. (transmission machinery)." No. 9 (pages 93 to 108), is on "engine guarding and engine stops," and No. 10 (pages 109 to 116), treats of "oiling devices and oilers." These pamphlets may be obtained for 10c. each by addressing the society or Edwin R. Wright, Editor, at Chicago.

They are accepted not only by the 4000 members of the council, but generally, as standard safe practices to protect the lives and limbs of workers. Accident prevention is now recognized as of supreme importance if for no other reason than to keep every man on the job producing materials to help Uncle Sam win the war.

Obituary

James Stackhouse, for many years superintendent of buildings for the John Hancock Mutual Life Insurance Co., of Boston, Mass., died at his home in West Roxbury, Feb. 8. He was in the sixtieth year of his life, and had spent 28 years in the service of the John Hancock Co. Mr. Stackhouse was born in St. John, N. B., and most of his early life was spent at sea as a marine engineer, having made several trips around the world. Entering the employ of the Hancock Steamboat Co., he later became chief engineer of one of the passenger steamers. He was afterward in the employ of the Suburban Electric Co as chief engineer, followed by a similar position at the Mason Building, on Kilbey St., Boston, which position he resigned to become chief engineer of the building at 178 Devonshire St., now known as the Old John Hancock Building. Mr. Stackhouse was one of the oldest members of Massachusetts No. 1, M. A. S. E., of Boston, and always took an active interest in the welfare of that organization. Edward H. Kearney, who for many years served as chief engineer of the John Hancock Building, under Mr. Stackhouse, succeeds the latter in the position of superintendent of buildings for the company.

Personals

James A. Campbell has resigned his position with the Renfrew Manufacturing Co., Adams, Mass., to take a position as mechanical superintendent with Lever Bros., Cambridge, Mass.

H. W. Fuller has been appointed vice president in charge of operation of the Northern States Power Co., with headquarters at Minneapolis. H. M. Byllesby & Co. announce the creation of this position to relieve R. F. Pack, vice president and general manager, of operating responsibilities which have increased greatly due to the rapid growth of the Northern States organization. Mr. Fuller has been associated with Byllesby & Co. for seven years, devoting a large part of his time to the solution of special operating problems.

H. H. Harrison, of the Merchants Heat and Light Co., Indianapolis, Ind., has a vigorous policy as to patriotic, civic and public matters. His theory is that any institution that works industriously for the good of a city, county, state or nation will in turn be treated generously by the community. In short, in serving the public you are serving the company. Last fall he inaugurated a campaign to send useful Christmas gifts to the French tots who had been crying for a Santa Claus for three long years. The effort put forth resulted in 18,000 gifts sent to the little French children. His company has vigorously pushed Liberty Loans, and is now pushing Food Conservation, Thrift Stamps and Comic Valentines made by celebrated Hoosier caricaturists and authors. These valentines are sold for the benefit of the French Relief.

Engineering Affairs

The Southwestern Electrical and Gas Association will hold its annual convention on Apr. 15 at Galveston, Tex.

The American Institute of Steam Boiler Inspectors of New York City held its regular meeting in the Engineering Societies Building, 29 West 39th St., on Thursday, Jan. 31. The officers of the past year were reëlected as follows: T. T. Parker, president; J. G. Shaw, vice president; M Fogarty, treasurer; J. H. Pollard, secretary. The annual dinner will not be held because of the conditions caused by the war.

The New York Section of the American Society of Refrigerating Engineers, at its next meeting, Tuesday, Mar. 15, will hear a paper by Charles H. Bromley, associate editor of "Power," on "Some Specific Fuel Wastes and Their Reduction." The paper will be illustrated with lantern slides. The meeting, to be held at Machinery Club, 50 Church St., New York City, will be preceded by a dinner, also in the club. Van R. H. Greene, consulting engineer, 50 Church St., New York City, is secretary of the New York Section and has charge of the arrangements.

The Boston Section of the A. S. M. E., combined with the American Institute of Electrical Engineers on the evening of Tuesday, Feb. 5, at the Massachusetts Institute of Technology to listen to a paper by Prof. Walter I. Schlieter, of Columbia University, on "The Modern Trend of Education." The paper was discussed by Professor Franklin, of Lehigh, Professor Brozel, of Yale, Professor Clifford, of M. I. T., and several other prominent educators. Representatives of the American Society of Mechanical Engineers were Parker H Kemble, of the U. S. Shipping Board; Captain Foster Veitenheimer; Dr. Ira N. Hollis, president of Worcester Polytechnic Institute; A. L. Williston, of Wentworth Institute; Director Russell, of Franklin Union, and Mr. Hall, of the General Electric Co., Lynn, Mass. These speakers covered the special problems in training for the Army and Navy, as well as for the mercantile marine, munition factories and other industries directly concerned in the prosecution of the war, and particularly in reference to the utilization of existing technical schools in New England for the training of large numbers of men for such service

Miscellaneous News

A. Newlands, Engineering Chief of the Highland Ry., in the course of a paper on "Water Power in Great Britain," before the Royal Society of Art, said that turbines for a head of 25 ft. cost £4 per horsepower as against £1 per horsepower for a head of 500 feet.

A Boiler Exploded at the plant of the Republic Iron and Steel Co., East Chicago, Ind., on Feb. 18. Two employees were instantly killed and two others died later in a hospital. Of the 29 injured, two are not expected to live. The plant was partly wrecked, with an estimated loss of $500,000.

Radio Engineering at Lafayette—Prof. James T. Rood has started a course in radio engineering in connection with the prescribed course of electrical engineering at Lafayette College. This course was designed and approved by the Signal Corps of the United States Army in order that the engineering students, subject to the selective draft, might enter this course and receive thereby the deferred classification which would enable them to continue in their engineering courses at the college for the balance of the year.

Western States Petroleum Administrator—Prof. D. M. Folsom, head of the School of Mines at Stanford University, Calif., on Feb. 6 was appointed petroleum administrator for the Western States by Mark L. Requa, national oil administrator. Professor Folsom has been serving as chairman of the petroleum committee of the state fuel administrator in California and is one of the leading oil experts of the West. In his new capacity he will have supervision over the production and distribution of petroleum in California, Washington, Oregon, Idaho, Utah, Nevada, Arizona, Alaska and Hawaii. This appointment is taken to mean the abolition of the petroleum committee which consisted of Professor Folsom and two members of the Railroad Commission of California. Professor Folsom has announced that there will be no compulsory licensing of oil producers at present, as this would require the fuel administration to become immediately responsible for operation and production. A system of friendly coöperation rather will be practiced. "It will be necessary, however," he stated, "for all companies to pool their cars and tank ships to prevent shortages and embarrassment in deliveries." No limit is to be placed on fuel-oil consumption so long as storage conditions remain as they are at present."

Business Items

The Plant and Business of the Schutte & Koerting Co., of Philadelphia, has been taken over by the Government as a German-owned concern. Adalbert K. Fischer, its former president, is interned at Fort du Pont, Del., as a dangerous alien.

The Esterline Co., of Indianapolis, Ind., has appointed the Northern Electric Co., of Montreal, as exclusive distributor of Esterline products for the entire Dominion of Canada, and complete information and service may be had at its offices at Montreal, Halifax, Ottawa, Toronto, London, Winnipeg, Regina, Calgary and Vancouver.

The Marion, Indiana, Machine, Foundry and Supply Co. has taken over the entire business, good will, etc., of the Planet Steam Specialty Co., which has specialized in the manufacture of soot blowers for all types of water-tube boilers. Gordon C. Bennett, who was secretary of the latter company, has taken charge of the engineering department to develop the manufacture of a complete line of soot blowers for all types of boilers.

Wright-Austin Co. — After twenty-five years of producing the highest grade of steam specialties in close association, the Wright Manufacturing Co. of Detroit, Mich., the Austin Separator Co. and the Murray Specialty Manufacturing Co. have combined their interests under the name of Wright-Austin Co. The high standards of manufacture and service which have been jealously guarded by the older concerns will be maintained. The business will be continued at the present address and under the direction of the same officials as heretofore

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 21, 1918	One Year Ago	Feb. 21, 1918	One Year Ago
Buckwheat ..	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market

	F.o.b. Mines*		Alongside Boston†	
	Feb 21, 1918	One Year Ago	Feb 21, 1918	One Year Ago
Clearfields....	....	$3.00	....	$4.25—5.00
Cambrias and Somersets...	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago

*All-rail rate to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 21, 1918	One Year Ago	Feb. 21, 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$7.25—7.50
Buckwheat ..	4.30—5.00	2.75	5.50—5.80	6.25—6.50
Barley	3.25—3.50	1.95	4.00—4.25	3.50—3.75
Rice	3.75—3.95	2.20	4.50—4.80	4.50—5.00
Boiler	3.50—3.75	220	....	3.25—3.50

Bituminous smithing coal, $4.50—5.25 f.o.b.

Quotations at the upper ports are about 5c. higher.

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)...............	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading, Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Feb. 21, 1918	One Year Ago	Feb. 21, 1918	One Year Ago
Pea	$3.75	$2.80	$4.65	$3.70
Barley	2.15	1.85	2.40	2.05
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.10	3.65	3.00
Boiler	2.45	1.95	3.55	3.15

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois

Pratt, Jagger, Corona....	2.15	2.40	1.90
Black Creek, Cahaba ...	2.40	2.65	2.15

Goverment figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

PROPOSED CONSTRUCTION

Calif., Red Bluff—City is having plans prepared by E. A. Rollison, Arch., Redding, for the erection of an electric lighting plant.

D. C., Wash.—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at various Navy Yards, under Schedule No. 1697, steam and water brass, air, bibb, hose, pet, cutout oil, and stop cocks; Schedule No. 1698, steam and water composition bends, Y-branches, caps, couplings, crosses nipples, plugs, tees and unions, steam and water screwed reducing bushings, elbows and locknuts.

Iowa, Bloomfield—City plans to improve its electric-lighting plant and install new equipment including 2 electric generators, one 225 kw. and one 75 kw. alternating current, and two 150 hp. boilers.

Ky., Walton—The Walton Electric Light Co. is in the market for a 25 kw., 250 volt, 220 r.p.m. D. C. generator for direct connection through flexible couplings, a 10,000 gallon horizontal oil storage tank, 6-8 ft. in diameter, 3-16 in. shell and ¼ in. heads.

Mass., Everett—The J. Duncan Co., 7 Fulton Place, Boston, is in the market for machine lathes, blacksmith power punches, cutters, bolt drivers and all machinery used in small structural iron work.

Mass., Everett—The Town plans to install equipment in its incinerator to include a 3½ x 40 ft. conveyor belt, baling presses and binds with appurtenances. About $7,000 is available. A. Varney, Town Engr.

Miss., Clinton—City plans to build a brick addition to its electric lighting plant and install a 50 hp. engine. Estimated cost, $8850. A. Latimer, Mayor.

Mo., Kahoka—City plans to extend its electric transmission line from here to Luray, Williamstown, Clark City and Medill, about 16 mi. L. R. Sherrill, Supt.

Mo., Ozark—The Finley Light Co. plans to build an electric-lighting plant. Estimated cost, $15,000. G. T. Breazeale, Mgr.

Neb., Sidney—The Town will receive bids until March 12 for furnishing and installing one 250 hp. steam engine, two 200 hp steam boilers, one 200 kv.-a. 60 cycles, 2300 volt, A. C. generator, 1 steel smoke stack, feed-water pumps and automatic stokers, two 150 hp. internal-combustion oil engines and one 10,000 gallon fuel tank. R. D. Salisbury, 1415 East Colfax Ave., Denver, Colo., Engr.

N. J., Camden—City plans to build an electric-lighting plant. L. E. Farnham, City Engr.

N. Y., Chenango Forks—The Binghamton Bridge Co., Press Bldg., Binghamton, plans to build a concrete dam, 150 ft. long, a brick and steel power house and steel penstocks and install two 250 kw. water turbine-driven generators. Noted Nov. 27.

N. Y., Jamestown—The Crescent Tool Co., 200 Harrison St., plans to build a power station and concrete coal storage binds. New machinery, including a 1000 kw. steam turbine generator set and boilers will be installed. C. R. Swisshelm, Sales Mgr.

N. D., Maddock—City is having plans prepared by W. E. Skinner, Engr., 714 Plymouth Bldg., Minneapolis, Minn., for the erection of an electric-lighting system. Estimated cost, $7000. Noted Oct. 23.

Ohio, Youngstown—The Mahoning and Shenango Ry. and Light Co. plans to build a transmission line from here into the Mosier District. R. T. Sullivan, Mgr.

Okla., Chandler—The Washita Electric Power Co. plans to build a 50 x 75 ft. brick and concrete power house and improve and extend its distribution system. R. K. Johnston, Pauls Valley, Secy.

Penn., Philadelphia—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard, Philadelphia, under Schedule No. 1698, steam and water brass joints.

Penn., Philadelphia (Kensington)—L. S. Leberman is having plans prepared by A. J. Sauer & Co., Arch., 908 Chestnut St., for the erection of a 1-story, brick and concrete power plant, including the installation of pumps. Estimated cost, $10,000.

S. D., Mitchell—City is having plans prepared by Burns & McDonnell, Engr., Interstate Bldg., Kansas City, Mo., for improvements to the electric lighting system.

Tenn., Hampton—J. H. Edens plans to rebuild his electric-lighting plant which was recently destroyed by fire.

Tex., Canyon—The Canyon Power Co. plans to rebuild its plant which was recently destroyed by fire. J. K. Boring, Ch. Engr.

Tex., Del Rio—C. A. Lindsey, Wichita, Kan., and associates, plan to build 1 or 2 hydro-electric plants in connection with a large irrigation project.

Wash., Puget Sound—(Bremerton P. O.—The Bureau of Supplies and Accounts, Navy Dept., Wash., will soon receive bids for furnishing at Navy Yard, Puget Sound, under Schedule No. 1698, steam and water brass joints.

B. C., Vancouver—The Ontario Power Co. plans to issue $1,000,000 bonds; the proceeds will be used to build additions to its plant.

POWER

Vol. 47 NEW YORK, MARCH 5, 1918 No. 10

On Being a Good Loser

Contributed by H. S. Knowlton, Cambridge, Mass.

IT IS not given to every engineer to advance steadily in his profession without setbacks which at times wear a discouraging aspect. The power to take the long look forward, to be a good loser if one is temporarily held back, and to learn the utmost possible from apparent failures is almost invaluable. Take the matter of promotions. Sometimes a plant chief resigns or passes away, leaving a second in command who feels himself the logical successor, and along comes the plant owner with a new man for the post of command, or, harder than this, he appoints a younger man from below in the organization in place of the former chief. Experiences like these put upon the "heir apparent" to the chief engineership a strain which sometimes causes him to offer his resignation at once in the belief that he is no longer appreciated and that the future in this particular station holds nothing for him.

THE GOOD loser in a situation of this kind conceals his feelings at least for the time being and never makes the mistake of jumping too rapidly to conclusions. His disappointment at being blocked in his logical progress may be taken for granted; but instead of losing his temper and acting hastily, he immediately begins a personal stock-taking. The problem is to find the reason why someone else was called to "go up higher," and the man who can analyze a situation of this kind regardless of how hard it may hit himself is at least fortunate in being able to look facts in the face. Now there may be a hundred reasons why he was not selected to command the installation. Some of them haven't the slightest relation to his personal efficiency. Cases are not unknown where an unfair choice is made through favoritism, family connections, misunderstanding of the inside situation, or some other cause beyond the control of the engineer. What concerns *him* is his own record in the plant, his own fitness for larger responsibilities.

NOTE the course of the good loser. He subjects his work to a severity of scrutiny which is bound to bring out every weakness of performance and, in most cases, every important lack in qualifications. Rigid self-examination helps mightily to establish the true inwardness of the new appointment. Then the engineer begins to study the ways and knowledge of his new chief and seeks to learn what he can from him to improve his own efficiency. His loyal service continues. Time passes, and ultimately the truth comes home to him. If the superiority of the new chief is established in his mind—and it takes pluck to realize it—the good loser may decide to continue in his present post, striving constantly to do better work and attain a broader mastery of his profession. On the other hand, he may become convinced that better opportunities lie elsewhere, and quietly but deliberately may begin to lay his plans to become established in another installation. Whatever the decision, it is not hasty, and it is the outcome of mature study which not seldom points the way toward more efficient service. Personal "preparedness" often grows out of difficult and trying situations in connection with the organization and direction of power-plant personnel. And it should not be forgotten that sometimes the new chief proves less adapted to command than the good loser, whose fitness is demonstrated thereby and who may come into his own by refraining from rash generalizations while sticking harder than ever to his job.

Walnut Plant, Columbus Railway, Power and Light Co.

This plant is ten miles from the center of the city and will have a capacity of 31,250 kv.-a. The boilers are arranged on the unit system, each unit consisting of two boilers, one economizer, two stokers, one induced- and one forced-draft fan. No bypasses are provided for the economizers. Each unit is to operate continuously or shut down as a whole when necessary. With three exceptions auxiliaries are electrically operated. All equipment requiring attention is on the main-floor level. The circulating and condensate pumps are of the vertical motor-driven type.

THE Columbus Railway, Power and Light Co. operates the street cars and supplies light and power for the City of Columbus, Ohio, its surrounding suburbs and near-by villages. This company has a number of old power stations, some of which are becoming inoperative due to one reason or another. The company still owns the site and buildings that were used for the first commercial generating station built in Columbus, and the first Edison station, started nearly thirty years ago, is still in operating shape and used considerably at times. For a number of years the company has had plans under consideration for new power-plant equipment, and in the last two years this problem became extremely active owing to the large increase in the industrial load and to the necessity of securing more economical operation.

Because of the scarcity and quality of water for condensing purposes and the lack of space for coal storage, it was considered desirable to find a site for a new power station outside of the city. The location chosen is ten miles southeast of the center of the city at a point where the Hocking Valley Ry. crosses Big Walnut Creek. The site consists of 25 acres of rolling ground on the east bank of Walnut Creek, with the railroad running through about the center of the property. The map of the property, Fig. 15, shows the location of the plant and the railroad tracks for coal-storage purposes and proposed operators' houses. Big Walnut Creek is formed by three small streams that come together about a mile above the site of this plant. There are approximately 500 square miles in the watershed of Big Walnut above the plant site, and there is a natural pool in the creek at the station varying in depth at low water from 15 to 20 feet.

The plant, Fig. 1, is located on the north half of the property, the low ground of this part being used for coal storage and the other part for houses for the operators and for coal storage. It will be the policy of the company to carry sufficient coal in storage, when it can be obtained, to run the plant for three or four months at a time.

The site for the Walnut Station was purchased in January, 1917. Active work was started in April, and the station began regular operation Nov. 18, 1917. This was accomplished in spite of delays in nearly all shipments of equipment and in the midst of a difficult labor market.

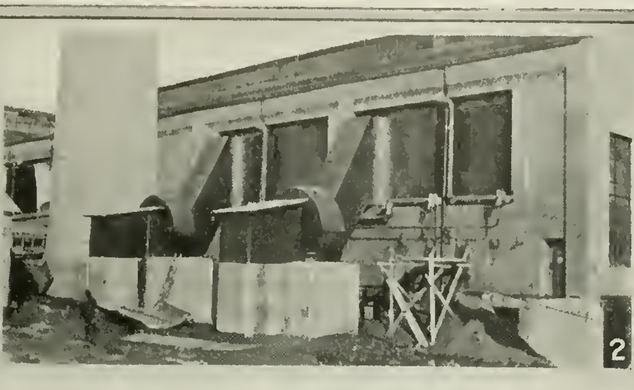
That part of the station now in operation consists principally of one 18,750-kv.-a. 60-cycle turbine, Fig. 5, and eight 440-hp. boilers provided with underfeed stokers. The plans include a second turbine, capacity 12,500 kv.-a. and eight additional boilers. This equipment is under order, and it is expected that it will be ready for installation in the early part of 1918. Fig. 9 is a plan view of the completed plant.

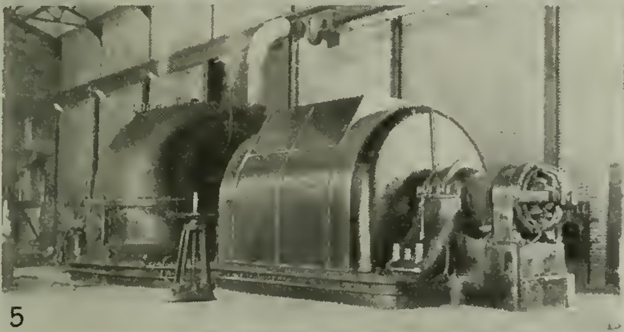
The boiler plant will consist of 16 cross-drum water-tube boilers, each having a heating surface of 4440 sq.ft. The present boiler and turbine installation gives 1.9 kw. turbine capacity per square foot of boiler-heating surface. With the second turbine and eight additional boilers there will be a ratio of 1 sq.ft. of boiler-heating surface to 2.27 kw. of turbine capacity. Each boiler has 21 sections of tubes, each section consisting of 10 tubes 18 ft. long and 4 in. diameter. Single-loop superheaters are also provided, each having 855 sq.ft. of heating surface, which will give about 150 deg. superheat under average conditions. This gives a ratio of 5.19 sq.ft. of boiler-heating surface to 1 sq.ft. of superheater surface. These boilers are designed for 250 lb. steam pressure and are provided with mechanical soot blowers, feed-water regulators, balanced-draft regulators for opening the outlet dampers and with furnace meters which record the steam flow, air flow through boilers and the temperature of the exhaust gases and also indicate the draft under the stokers.

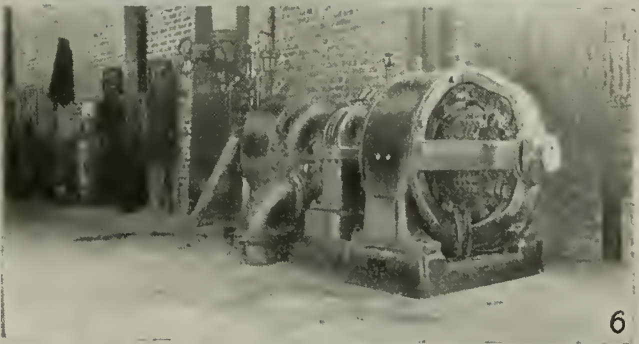
The boilers are set two in a battery, and each boiler is provided with one 8-retort underfeed stoker. The gases from each battery of boilers pass through one economizer having 6300 sq.ft. of heating surface, or 1.4 sq.ft. of boiler-heating surface per square foot of economizer surface. Each economizer has 32 sections, each section consisting of 12 tubes, 12 ft. long and 4⅝ in. outside diameter. The gases are conveyed from the boiler to the economizer by means of $\frac{5}{16}$-in. steel-plate flues covered with 1½ in. of asbestos. The gases from each economizer are in turn conveyed from the economizer by uncovered steel breechings to one 60,000-cu.ft. per min. induced-draft fan, Figs. 2 and 9. These fans are direct-connected to 75-hp. variable-speed motors. The fans discharge downward into a concrete flue, located below grade, which connects into the base of a tapered concrete chimney having a height of 150 ft. and an inside diameter at the top of 14 ft. 6 in. There will be two of these chimneys, one chimney accommodating four fans and eight boilers. The economizers are provided with the usual scraper mechanism, and one 5-hp. 720-r.p.m. motor drives the scrapers on two economizers.

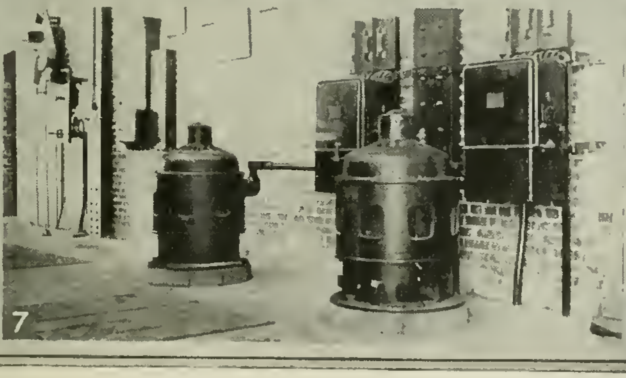
It should be noted that the boilers are arranged in units of two boilers, one economizer, two stokers, one induced-draft fan, one forced-draft fan, and that no bypasses are provided for the economizer. It is expected to operate this unit continuously and when necessary to make extensive repairs, to shut down the entire unit. Of course either one of the boilers may be shut down for cleaning without disturbing the operation of the other. The stoker, forced- and induced-draft fans are all driven by motors, the controllers for which are located convenient to the boilers and are under the control of the boiler-room operators.

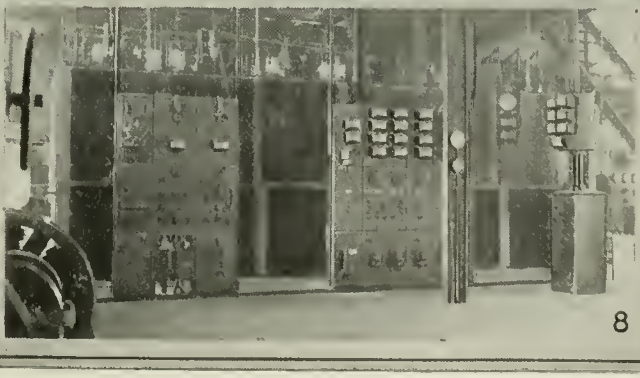
The balanced-draft equipment will provide the close regulation of the induced draft, and the large steps in the adjustment of this draft are obtained by the variable-speed motors, which are hand-controlled. The forced draft is also hand-regulated by varying the speed of the motors and by the movement of the dampers in the air ducts.











FIGS. 1 TO 8. GENERAL VIEWS IN AND ABOUT THE NEW POWER PLANT

Fig. 1—View of turbine room from river side, showing intake- and discharge-water tunnels, feed-water purifying plant and a portion of outdoor 39,400-volt bus structure. Fig. 2—Showing induced-draft fans for boilers 1 and 4 and openings in walls for economizers. Fig. 3—General view of plant from boiler room, showing coal- and ash-handling equipment, induced-draft fans and concrete stack. Fig. 4—Coal-storage track. This track showing elevated steel support track mounted on concrete piers. Fig. 5—The 18,750-kv.-a. turbine, showing generator end at the right with direct-connected exciter and main steam pipe for turbine. Fig. 6—The 100-kw. turbo-exciter set. Fig. 7—Two 35-hp. 220-volt, three-phase, alternating-current vertical constant-speed motors with controllers for driving condensate pumps. Fig. 8—General view of switchboard panels and bus structure; the panels at the left are for control of exciter, panels in the center are for control of outgoing lines and pedestal at the right controls turbine.

The economizers are operated in parallel and feed direct into the feed-water header, and to avoid unequal feeding from the economizers there are monel-metal orifices in the feed-water header between the connections to the economizers, the feed-water branch pipe to each boiler connecting to the header at a point between the orifices. As for the fine adjustment of the feed to the economizers, it is expected to obtain this by regulating the opening of the valves in the connections between the economizers and the header, determining the adjustment of these valves by the temperature of the feed water leaving the economizers, as shown by recording thermometers. In addition to the recording furnace meters, there are recording thermometers for the gases leaving the economizers and for the water entering and leaving the economizers and also for the water entering the feed-water heater. Fig. 11 is a cross-section of the boiler room.

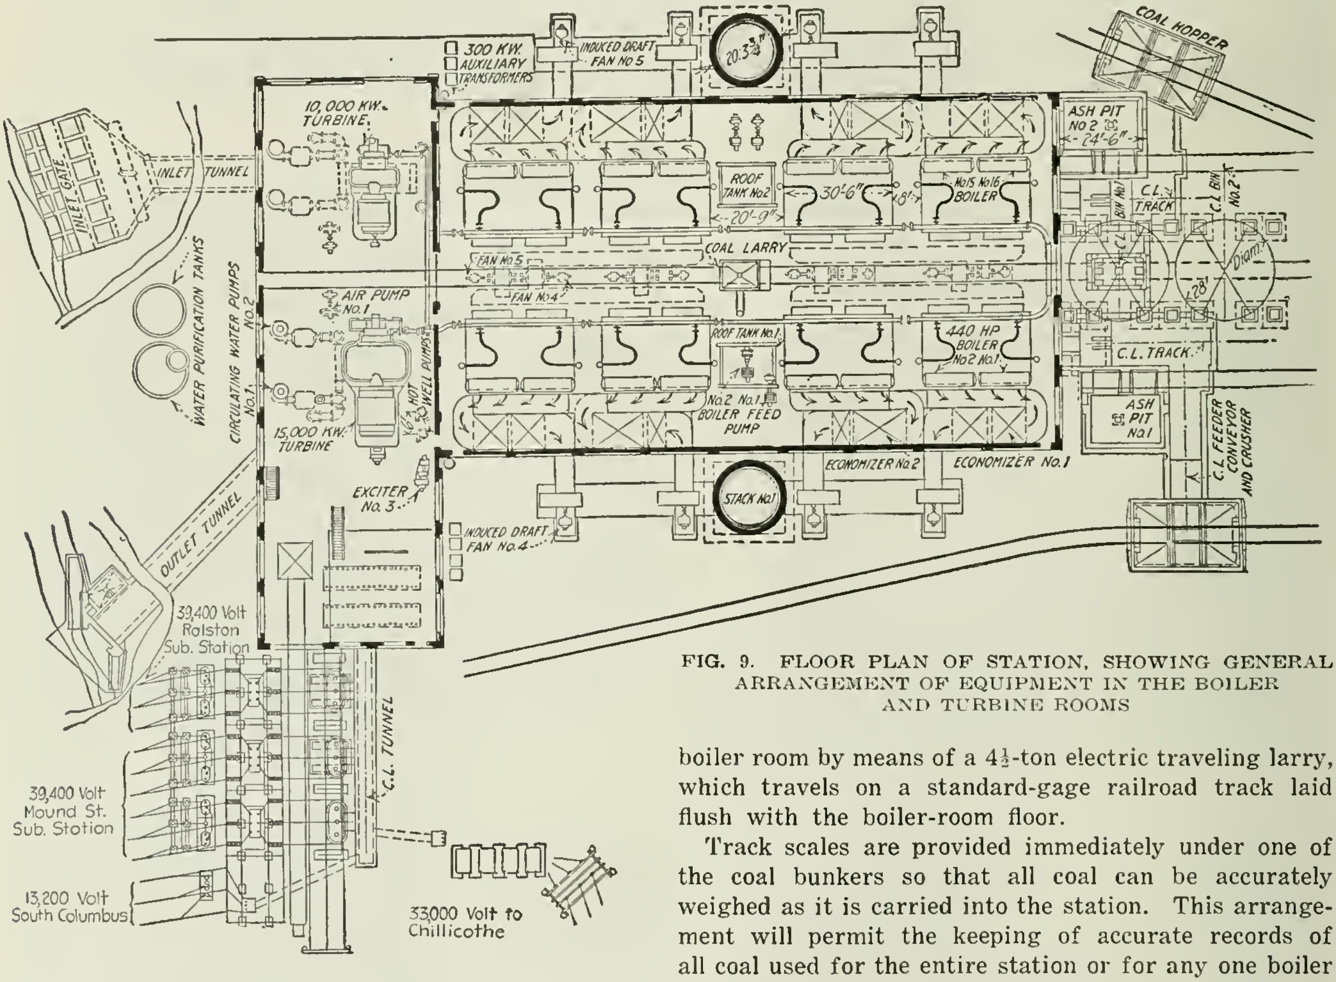


FIG. 9. FLOOR PLAN OF STATION, SHOWING GENERAL ARRANGEMENT OF EQUIPMENT IN THE BOILER AND TURBINE ROOMS

For supplying the makeup water for the boilers, that is, water over and above that secured from the surface condensers, a lime and soda-ash feed-water purifying plant is installed. It is placed outside of the building, as shown in Fig. 1. This plant consists principally of two 20,000-gal. wood-stave tanks with stirring mechanism, and an elevated dosing tank. The river water is of fairly good quality except during high water, when it may be quite roily.

Four 4-stage centrifugal pumps supply the boilers with water. Three are motor- and the other one is turbine-driven. The water rate of the turbine at full load is 49 lb. per brake-horsepower.

The steam from the boilers will be carried through 6-in. steam lines to a main 12-in. steam header. Each row of eight boilers will be provided with a 12-in. steam header, the two headers being connected together at each end so as to form a ring. In the same way the feed water will be supplied to the boilers from a 6-in. feed-water header for each row of boilers, and the feed-water headers will be connected across so as to form a loop.

The equipment for handling the coal and ash is very complete. The station will be provided, when completed, with two 400-ton coal bunkers located just outside of the boiler room at the end of the station, Figs. 3 and 13. Coal will be supplied to these bunkers from two track hoppers, the coal passing from the track hoppers by means of a flight conveyor through a coal crusher and thence by bucket elevator to the top of the coal bunkers. The coal from the bunkers will be carried into the boiler room by means of a 4½-ton electric traveling larry, which travels on a standard-gage railroad track laid flush with the boiler-room floor.

Track scales are provided immediately under one of the coal bunkers so that all coal can be accurately weighed as it is carried into the station. This arrangement will permit the keeping of accurate records of all coal used for the entire station or for any one boiler over any particular period. The larry is electrically operated, has a revolving bin which works like a turret, and is provided with a screw conveyor which supplies the boilers on either side of the firing aisle. The larry requires only one man for its operation, is simple in construction, and all wearing parts are accessible for repairs.

The foundations for the boilers are of concrete and form the ashpits. Two drag-chain conveyors pass under each row of eight boilers, conveying the ash out to the end of the station and discharging into a clinker crusher, which in turn discharges into the boot of a bucket elevator. This elevator may discharge either into a concrete ashpit, shown at the right of Fig. 9, or into railroad car or wagon. The ash can be disposed of for a long time by grading around the property. Each drag-chain conveyor has sufficient capacity for carrying out the ash, and duplicate conveyors are furnished so as to allow repairs and changes to be made without inconvenience to operation, as arrangements are made so that either one can be isolated for repairs without interfering with the other.

The coal will be distributed over the ground and reloaded into cars for moving into the station by means of a 15-ton steam-driven locomotive crane provided with a 2-yd. grab-bucket.

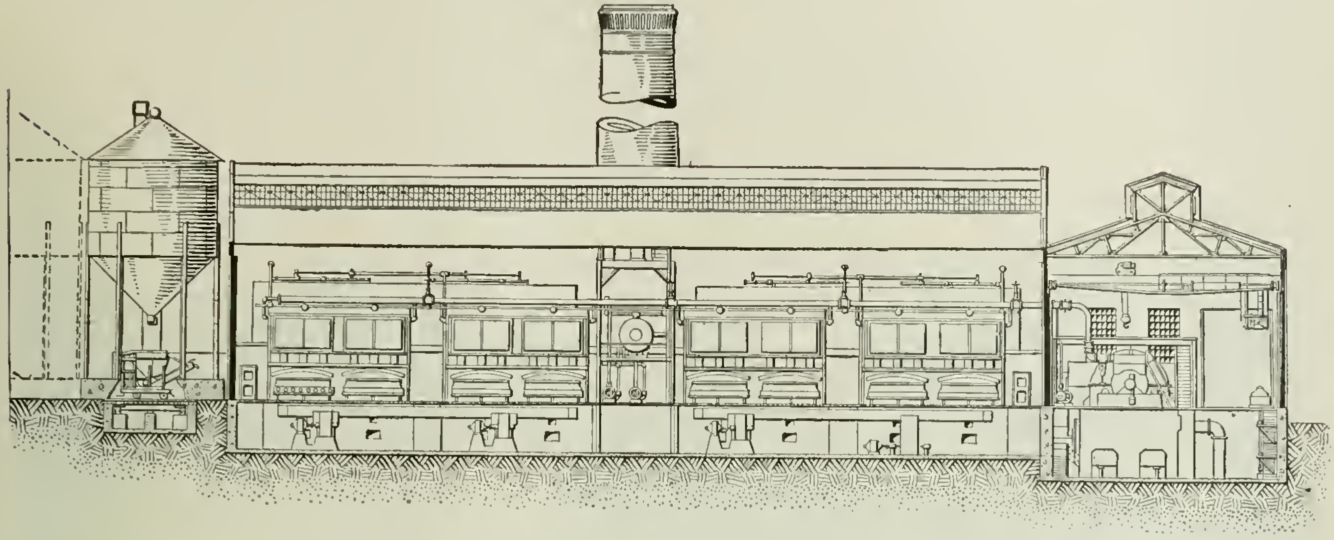

FIG. 10. LONGITUDINAL SECTION OF BOILER ROOM AND A CROSS-SECTION OF TURBINE ROOM

The coal bunkers have capacity sufficient for one to two days' operation of the station. To provide against car shortage and irregularity of shipments, an elevated storage track is provided, a track 480 ft. in length being elevated approximately 15 ft. over low ground, Fig. 4. Since practically all the coal received is in hopper-bottomed cars of one type or another, no labor will be required for unloading them. This track is supported by reinforced-concrete piers, 14-ft. centers, and supported between piers by steel I-beams with steel cross-members on 5-ft. centers to prevent spreading.

The generators are connected to the 13,200-volt bus through oil switches, and a transfer bus is provided with a transfer switch so that any 13,200-volt switch with its instrument transformers may be cut out of service and worked on when necessary without interrupting service. All feeders and other circuits are provided with the same type of oil switch, and all of them are remote-controlled from the switchboard. All the turbine controls are also located at the switchboard.

The auxiliaries in the station will be electrically operated with the exception of one boiler-feed pump

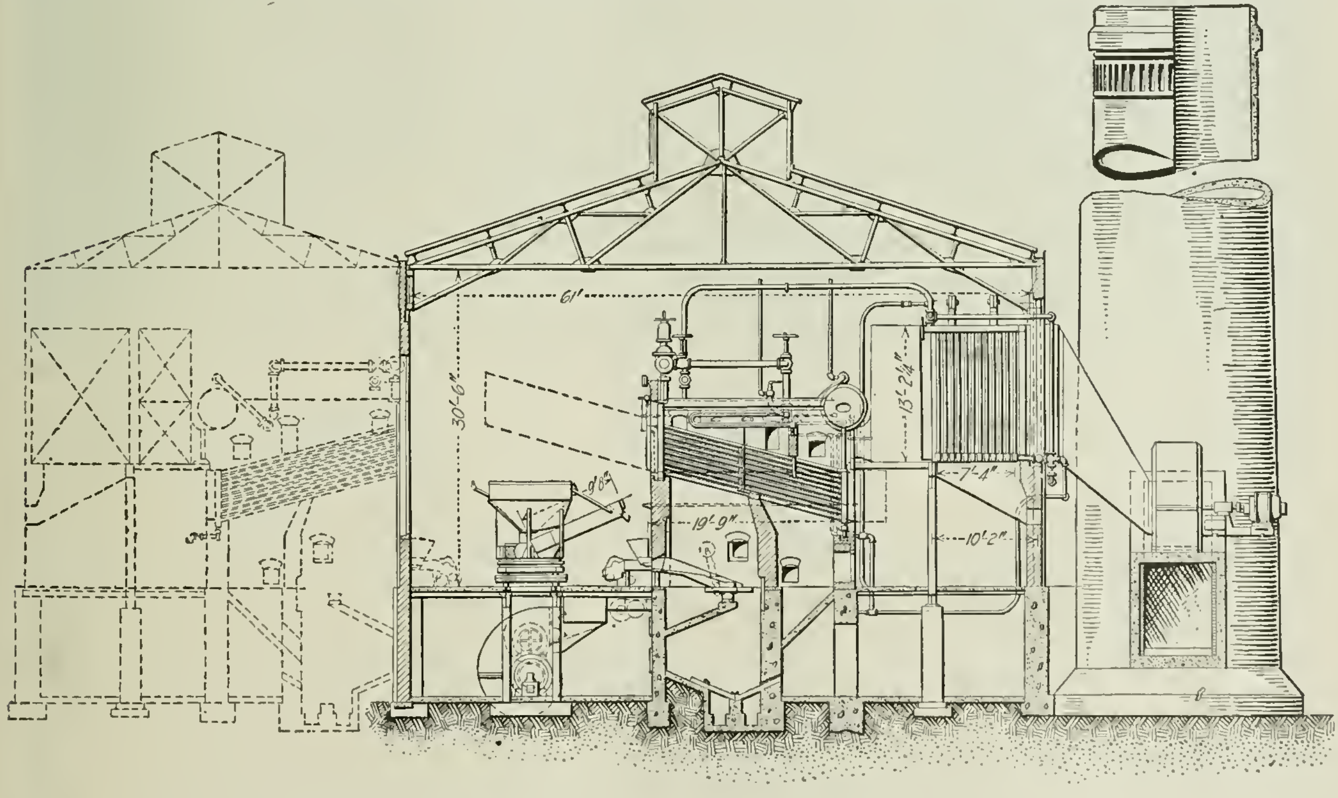

FIG. 11. CROSS-SECTION OF BOILER HOUSE, SHOWING PRESENT AND FUTURE BOILER ROOM AND ARRANGEMENT OF FORCED DRAFT, STOKERS, FLUES, ECONOMIZERS, ETC.

and two dry-vacuum pumps. The current for supplying these motor-driven auxiliaries will be supplied by two duplicate banks of three 300-kv.-a. single-phase 13,200-volt to 220-volt outdoor type self-cooled transformers. The total connected load of motors for auxiliaries in the station will amount to 2533 hp.

Each turbine is provided with a direct-connected 100-kw. 250-volt exciter, and a 100-kw. 3600-r.p.m. geared turbo-exciter set is provided for spare service, Fig. 6.

The plant is laid out with the idea of having all equipment that requires attention on the main-floor level, or elevation 740, this applying to the switchboard, turbines, motors for driving circulating water pumps and hotwell pumps, controllers for all forced-draft, induced-draft and stoker drives, battery-charging set, etc. Therefore there will be as small occasion as possible for the operators leaving the main floor.

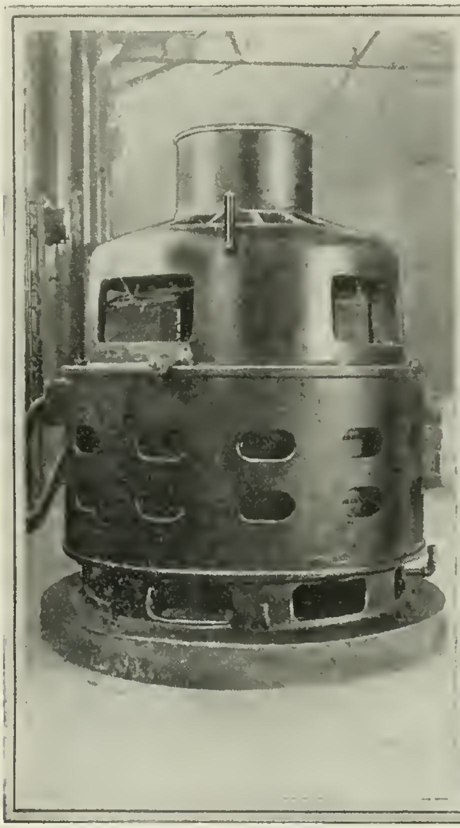

FIG. 12. A 120-HP. VERTICAL VARIABLE-SPEED, 220-VOLT, THREE-PHASE, ALTERNATING-CURRENT MOTOR FOR DRIVING ONE OF THE CIRCULATING WATER PUMPS

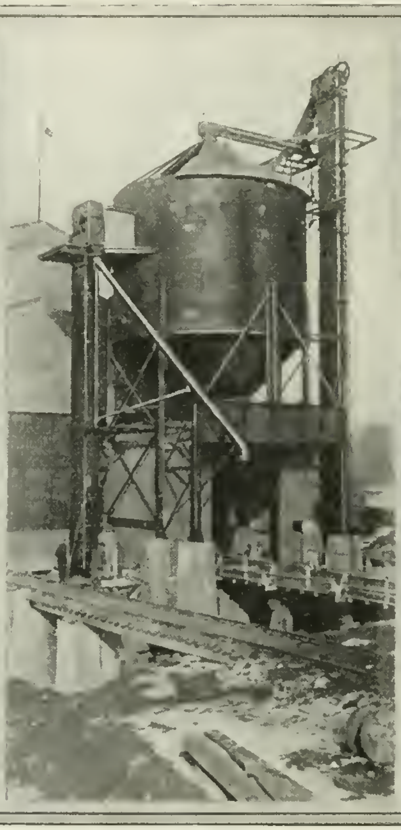

FIG. 13. VIEW OF COAL BUNKER AND ASH ELEVATOR. THE ELEVATOR AT THE LEFT WITH THE LONG CHUTE HANDLES THE ASH

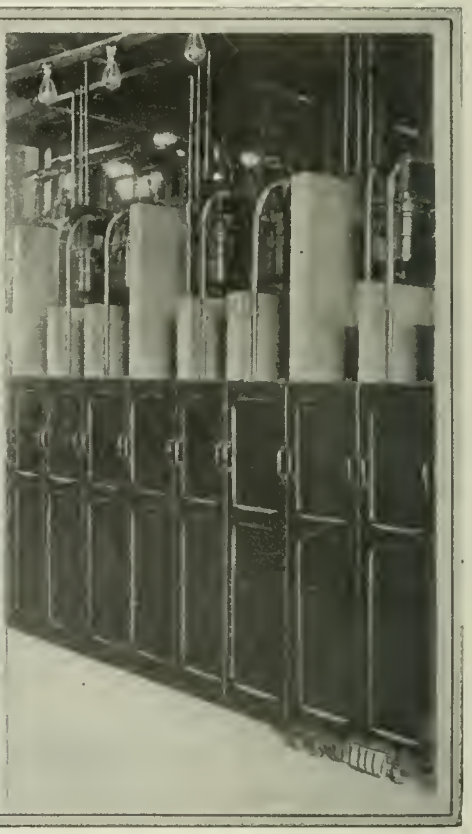

FIG. 14. A PORTION OF 13,200-VOLT SWITCH CELLS, SHOWING LOCATION OF POTENTIAL TRANSFORMERS. DISCONNECTING SWITCHES ARE BACK OF THE REMOVABLE DOORS

Each turbine is provided with a surface condenser, and each condenser will be supplied with circulating water by duplicate vertical variable-speed motor-driven circulating-water pumps. These pumps, Fig. 12, receive water from a gravity tunnel which runs under the length of the turbine room, and the water from the condensers discharges into another separate gravity tunnel, which also runs the full length of the turbine room and carries the water out into the river at a point about 160 ft. below the intake. Each condenser is also provided with duplicate vertical motor-driven single-stage centrifugal condensate water pumps, Fig. 7. Therefore, by the supplying of these duplicate sets of circulating water and hotwell pumps it is possible to avoid many reasons for shutdown.

The circulating water being carried into the station by a concrete tunnel and in turn being carried out by the same means, eliminates the usual large amount of piping required for circulating water and also supplies the water at a convenient point with minimum waste of power. The water in the tunnel will have a velocity of about 2 ft. per sec. with two turbines carrying full load and about 3.1 ft. per sec. with 40,000-kw. turbine capacity in operation. The discharge-water lines from the condensers are sealed in the discharge tunnel so that advantage is taken of the siphon action obtained thereby.

The intake end of the tunnel is enlarged and provided with a large area of racks (velocity through racks 0.5 ft. per sec. first two units and 0.8 ft. per sec. for 40,000 kw. of turbines in operation) for the water to flow through. There are also provided six large removable wire baskets (1-in. mesh) which should catch nearly all the leaves, twigs, etc., that may come downstream during high water. Each basket is in a separate compartment provided with a gate for shutting off the flow of water when the basket is raised for cleaning. A traveling hoist is provided for operating the gates and baskets. Such particles of leaves, twigs, etc., as pass through these baskets and racks can be removed before reaching the condenser by means of twin strainers (⅜-in. holes) which are located between the circulating-water pumps and the condensers. The circulating-water pumps are immediately on top of the intake tunnel so that a minimum suction lift of about 11 ft. is secured.

A battery of four 200-gal. per min. motor-driven centrifugal pumps is located in the basement of the turbine room for furnishing water to the feed-water purification plant, for the cooling of bearings and for the 15,000-kv.-a. transformers.

The condenser of the 18,750-kv.-a. unit is bolted direct to the exhaust flange of the turbine without any expansion joint, Fig. 16. Car springs are placed below the condenser and so compressed as to balance the weight of the empty condenser. These springs will allow the condenser to expand when heated, and the turbine is capable of taking the additional weight of the water which may be in the condenser during regular operation.

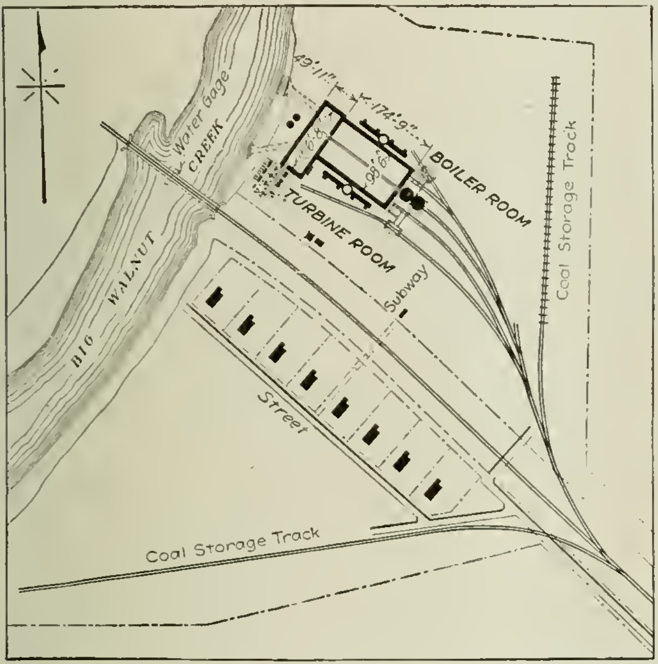

FIG. 15. PROPERTY MAP SHOWING GENERAL ARRANGEMENT OF TRACKS AND LOCATION OF PLANT, COAL STORAGE AND OPERATORS' HOUSES

The condensate from the condenser is forced by the centrifugal pumps to the top of the boiler room, where the water will flow through water meters into an open storage tank. This tank is divided into two compartments, one compartment with a capacity of 6000 gal. for condensate and one compartment with a capacity of 3000 gal. for makeup water. The water from this storage tank will flow through an open feed-water heater having 1300 sq.ft. of heating surface. The feed-water heater is divided into two parts; the condensate will pass over one-third and the makeup water over two-thirds of the heating surface. From the heater the water will pass through a battery of four 400-gal. per min. four-stage centrifugal boiler-feed pumps, three of these pumps being driven by 100-hp. three-phase 60-cycle 220-volt 1740-r.p.m. motors, and the fourth by a steam turbine, 1850 r.p.m. The pumps will discharge direct into headers supplying the economizers, the economizers carrying full boiler pressure plus the additional pressure required for forcing the water through the economizer to the boilers.

As the station is situated about ten miles from the center of distribution of the current in Columbus, it was thought desirable to transmit at a higher voltage than that generated. Therefore the current will be carried into the city over three transmission-line circuits at 39,400 volts, and one 13,200-volt circuit, the latter being the generating voltage, which will feed an industrial section at the extreme south end of the city. The electrical energy will be received at 39,400 volts at one point in the city at the present time and at second and third points later on. Current will be distributed in the city between substations and to large power customers at 13,200 volts; the primary voltage for all other light and power customers is 4150 volts four-wire distribution. The tie-lines between the principal substations of the city will operate at 13,200 volts and consist of triple-conductor lead-incased cables laid in vitrified-clay duct subways. Figs. 8 and 14 show the switchboard panels and a portion of the 13,200-volt switch cells respectively.

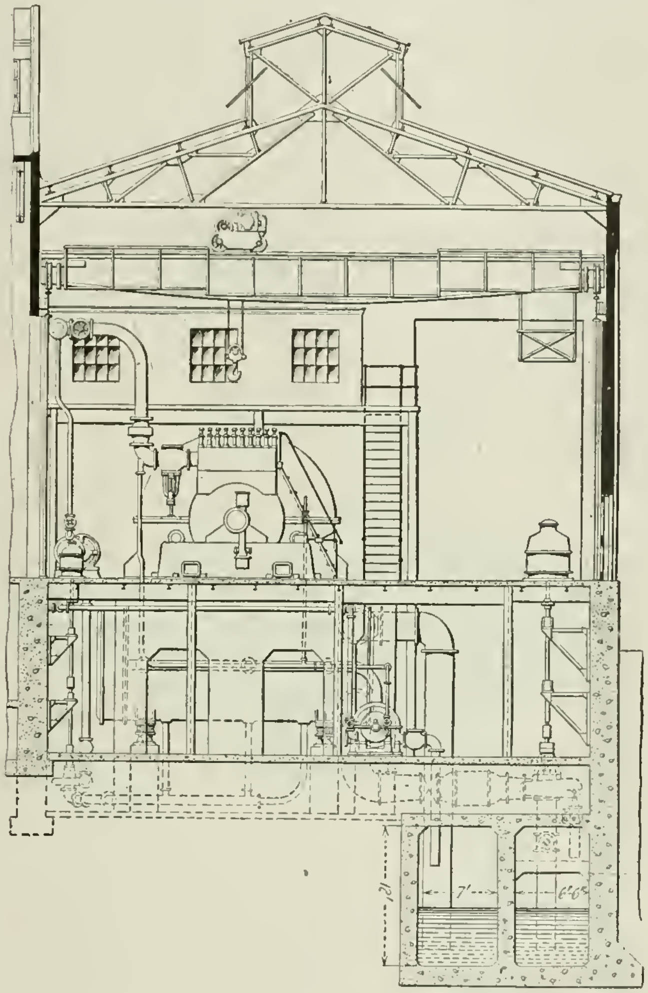

FIG. 16. CROSS-SECTION OF TURBINE ROOM, SHOWING SOME OF THE DETAILED ARRANGEMENT OF CONDENSING EQUIPMENT FOR THE TURBINE. ALSO SECTION OF WATER TUNNELS FOR CIRCULATING WATER

The current will be transformed from 13,200 to 39,400 volts at the power station by means of 15,000-kv.-a. three-phase 60-cycle water-cooled outdoor-type transformers. Two units will be installed this year and a third transformer at a later date. All switches for the 13,200-volt transformers and main generators will be located within the station, but all the 39,400-volt switches, lightning arresters and connections will be outside of the station. Provision is made for taking the transformers in the station on a truck so that they can be placed under the electrical traveling crane for disassembly for repairs and also for the original erection.

Very little space is required within the station for the electrical equipment. The control part is compact and only the 13,200-volt switches are within the station. All transformers, high-voltage bus structure, main-line switches and lightning arresters are located outdoors. Any of this equipment can be cut out of service and moved into the station for inspection and repairs, thus securing all the advantages of the outdoor-type of electrical equipment with minimum disadvantages.

The main building is a steel-frame structure supported on a reinforced-concrete foundation. The turbine room now completed for two turbines is 156 ft. 6 in. in length and 44 ft. 1 in. in width, is provided with a 35-ton electric traveling crane having a rail height of 25 ft. above the main floor. The turbine-room basement is 15 ft. high from floor to floor excepting under the condensers, where the height is 20 ft. The boiler room now completed is 174 ft. in length and 60 ft. in width and will be 174 ft. in length and 96 ft. 2 in. wide when completed for 16 boilers. The height under the lower chord of roof trusses is 30 ft. 6 in. The basement under the boiler room is 10 ft. 6 in. floor to floor.

The outside walls are built of hard-burned red brick, and the partition and temporary end walls of the turbine room are built of interlocking tile. Fenestra steel sash glazed with factory-ribbed glass are used throughout the building. Steel rolling doors are used for large doorways and steel paneled doors on all small doorways.

The roofs are supported by Fink trusses, ⅙ pitch, provided with monitors, ventilation being secured by opening sections of the steel sash by means of suitable window-operating mechanism. The roof for the boiler room consists of a concrete slab waterproofed with three-ply asbestos felt laid in asphalt. The turbine-room roof is similar except that a slab made up of a composition of gypsum and wood fiber is used, this construction being resorted to in order to avoid the possibility of condensation forming on the underside of the roof. The concrete slabs for roof and floors are supported by asbestos-protected corrugated metal with reinforcing fabric. The slabs are flat in both cases, being 2¼ in. thick for the roof and 4 in. for the floor.

The foundations for walls and equipment are supported on reinforced mats or footings which rest on hard river gravel or clay hardpan, the character of earth varying according to the elevation of the various foundations. Extensive soundings and test pits were driven to determine the nature of underlying earth previous to starting construction. A test pile was also driven in the deepest portion of excavation.

For the foregoing information and accompanying illustrations, *Power* is indebted to the E. W. Clark & Co. Management Corporation, who designed and constructed the Walnut Station.

PRINCIPAL EQUIPMENT OF THE PRESENT BIG WALNUT CREEK POWER PLANT, COLUMBUS, OHIO

No.	Equipment	Kind	Size	Use	Operating Conditions	Maker
8	Boilers	Water-tube	4,440 sq.ft. heating surface	Main steam generators	250-lb. steam, 150 deg. superheat	Babcock & Wilcox Co.
8	Superheaters	Single loop	855 sq.ft. heating surface	With water-tube boilers	150 deg. superheat under normal conditions	Babcock & Wilcox Co.
8	Soot cleaners	Diamond		Cleaning boiler tubes	As conditions demand	Diamond Power Specialty Co.
8	Regulators	Copes	2½-in.	Feed-water regulation	Automatic balanced regulating valve	Erie Pump & Equipment Co.
8	Meters	Bailey		Steam flow, air flow, draft	Automatic	Bailey Meter Co.
8	Stokers	Riley, self-dumping	8-retort	With steam boilers	Motor-driven, chain connection	Sanford Riley Stoker Co.
4	Economizers	Green, fuel	6,300 sq.ft. heating surface.	One serves four boilers	Under-pressure	Green Fuel Economizer Co.
4	Fans	Induced-draft	60,000 cu.ft. per min	Induced draft to furnaces.	Motor-driven, 3-in. pressure, variable speed.	Green Fuel Economizer Co.
4	Fans	Forced-draft	45,000 cu.ft. per min	Forced draft to furnaces	Motor-driven, 5½-in pressure, variable speed.	Green Fuel Economizer Co.
1	Fan	Forced-draft	45,000 cu.ft. per min	Forced draft to furnace	Motor-driven, 5½-in. pressure, variable speed.	B. F. Sturtevant Co.
4	Motors	Induction	75-hp.	Driving forced-draft fans	600 r.p.m., 220-volts, flexible coupling	Lincoln Electric Co.
3	Motors	Induction	75-hp	Driving forced-draft fans	600 r.p.m., 220-volts, flexible coupling	General Electric Co.
1	Motor	Induction	100-hp.	Driving forced-draft fan	900 r.p.m., 220-volts, flexible coupling	General Electric Co.

Rewinding Direct-Current Armatures

By R. THISTLEWHITE

The difficulties of winding armatures are easily overcome if a few general principles are kept in mind. These are given in a very brief form without any technical explanation, it being taken for granted that the statements are correct, and should the reader wish proof of the fact he can refer to any standard work on armature winding and find them.

WHEN an armature is to be rewound, the first thing to do is to count the number of slots in the core and the number of commutator bars, from which can be determined the distribution of the coils. Each coil has two sides, as in Fig. 1. Then (1) if there are one-half as many bars in the commutator as slots in the armature core, there will be only one side of a coil in each slot; (2) if there are as many bars as slots, there will be one side of two different coils in each slot; (3) if there are twice as many bars as slots, there will be one side of four different coils in each slot; (4) if there are three times as many bars as slots, there will be one side of six different coils in each slot. Always keep in mind that for every bar in the commutator there must be a coil in the winding.

As there is only one side of one coil in a slot in No. 1, this winding is known as a single-layer winding. In No. 2 there is one side of two different coils in a slot and the winding is called a two-layer winding. In No. 3 there is one side of four different coils in the same slot, therefore it is termed a four-layer winding. In No. 4 there is one side of six different coils in the same slot, consequently it is known as a six-layer winding.

Determining Spread between Coil Leads Connected to the Commutator

The next operation is to trace from the commutator along a lead to the slot it enters, then stretch a piece of string from the center of this slot to the end of the shaft and mark the bar the string passes over; count from this bar to the bar the lead is connected to, taking notice whether this is to the left or right when facing the commutator, Fig. 2, which shows the throw of the leads to be from 1 to 9 to the left. Now, mark bar 9 and lift up the leads about halfway round the commutator, then with a lamp test from the top lead in bar 9 and find the other end of the coil. Count the bars between these two points, including the two the coil's leads connect to, which will give the spread between leads, and with this information the coils can again be connected up to the commutator as they were originally.

There are two general ways of connecting an armature—parallel and series. In the former the spread between the leads will be one bar; that is, the two ends of the same coil will be found in adjacent bars, while in the latter the spread will vary, depending on the number of field poles in the machine. In four-pole machines the spread will be approximately halfway round the commutator, for a six-pole one-third, etc. In parallel windings the leads can usually both be lifted at the same time; that is, the beginning and ending of the coil, or as they are most commonly spoken of, the bottom and top leads. But in the series winding it is generally practice to place the bottom leads first, which are then covered with about two layers of tape, then the top leads are put down; therefore, when lifting the leads, the top ones would be lifted first. It will also be necessary to stretch the string as before and find the throw of the bottom leads in the same manner as the throw of the top leads was found, and also to observe the direction of the throw.

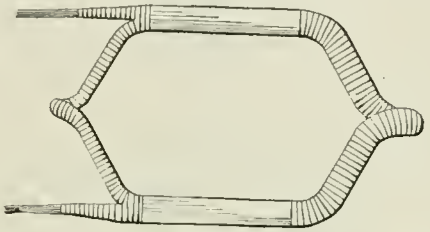

FIG. 1

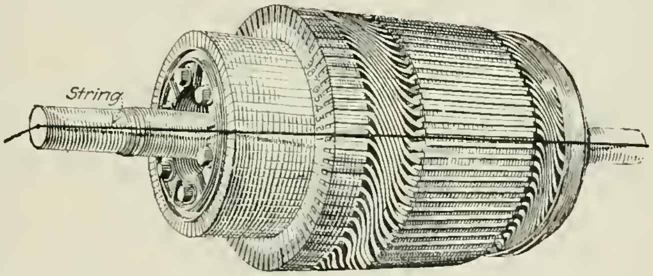

FIG. 2

FIGS. 1 AND 2. ARMATURE COIL AND ARMATURE WITH WINDING CONNECTED TO COMMUTATOR

The distance in bars between the bottom and top leads, counted so as to embrace the bars that the coil leads connect to, is the correct count of the lead spread. It will also be found, for a series winding, if the count is continued it will return to the adjacent bar started from. This is clearly indicated in Figs. 3 to 5. Figs. 3 and 4 show one series of coils connected to the commutator of a four-pole machine and Fig. 5 one series of coils connected to the commutator of a six-pole machine. This can be checked by building a short table thus: In Fig. 4 there are 39 commutator bars and for four poles the lead spread should be commutator bars plus or minus 1 divided by the number of pairs of poles; or, in this case, 39 plus 1 equals 40, 40 divided by 2 equals 20, then the coil leads spread bar 1, and bar 1 plus 20 equals 21; that is, the leads of one coil connect to bars 1 and 21. Continuing the count, bar 21 plus 20 equals 41; as there are only 39 bars, bar 40 would be bar 1 and bar 41 would be bar 2, as in the figure. The table will then read 1 and 21, 21 and 2, etc.

Coming back to the foregoing rule and using the minus sign, 39 minus 1 equals 38, 38 divided by 2 equals 19; then the lead spread would be 1 plus 19 equals 20 and 20 plus 19 equals 39, which is adjacent to bar 1. This is the condition in Fig. 3. The only difference between the connections in Figs. 3 and 4 is that with the motor connected to the line the same in both cases, the direction of rotation of the armature, when the minus sign is used, will be the reverse of that when the plus sign is used.

In the six-pole machine the spread of the leads would be equal to the number of commutator bars plus or minus 1 divided by the number of pairs of poles; in this case three counts have to be made before a series of coils encircle the commutator as in Fig. 5.

When the lead spread has been taken and checked, the armature can be stripped and the number of turns per coil counted and the size wire measured. The core is then cleaned of all old insulation and given a coat of shellac or other good insulating-compound varnish.

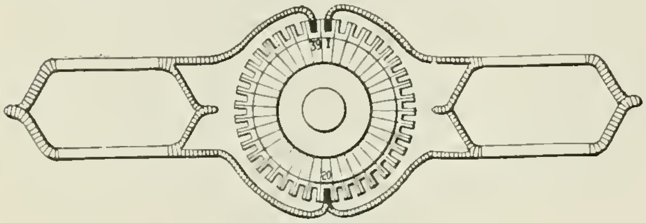

FIG. 3

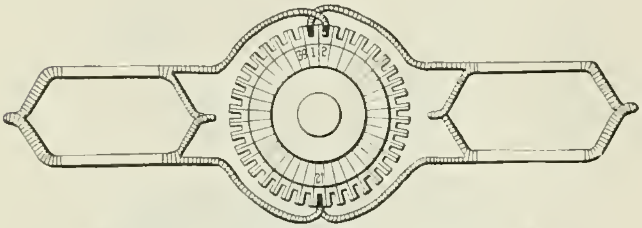

FIG. 4

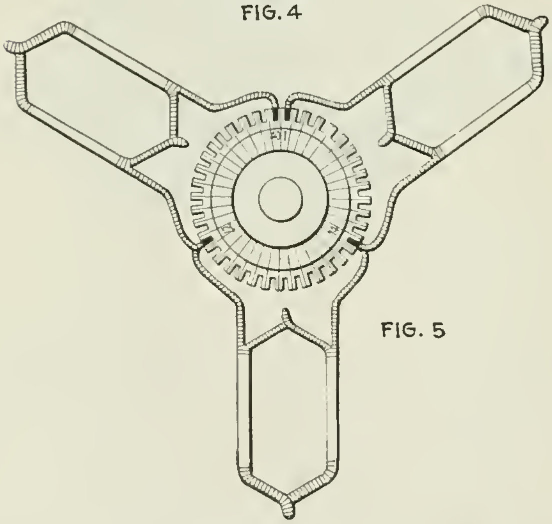

FIG. 5

FIGS. 3 TO 5. ONE SERIES OF COILS CONNECTED TO COMMUTATOR OF SERIES WINDING

Rewinding Four-Pole Armature

I have before me a four-pole armature that I am going to rewind, and will describe the operations as I go through them. I do not know the type of winding at the present time or the count, but from the foregoing it will readily be seen how to go about finding it.

The number of slots in the core is 15 and the number of bars in the commutator 29. Referring back to the data previously given, it will be found that this winding is four layer, that there is one side of four different coils in each slot. Two coils per slot would give 30 coils, and as we have only 29 bars, it would be impossible to connect them all, so one coil is wound in, but its leads are cut off short and it is not connected to the commutator. If this was not done, two slots would contain one side of only three coils instead of four, which would leave the armature out of balance mechanically and also allow the wires to move around in the slot and eventually destroy the insulation and cause grounds and short-circuits.

Stretching a string from the center of the slot to the center of the shaft, the top leads from one slot are found swung over to the left 6 and 7 bars. Since there is one side of four different coils in each slot, there are two bottom leads and two top leads coming from each slot. Lifting the leads about halfway round, the other ends of the coils are found brought out straight and the distance between these leads is from 1 to 15, or 14 bars between.

Checking the Winding Data

Checking this result, 29 minus 1 equals 28, divided by 2 equals 14; 1 plus 14 equals 15, 15 plus 14 equals 29, which is adjacent to bar 1 and is correct.

Before stripping the winding, measure the distance the end of the winding projects beyond the end of the core; in this case it is 0.75 in. The spread of the coil is found to be from slot 1 to 4. The winding can now be removed and the number of turns in one or two coils counted, which in the case in hand is 10 turns.

These results must be tabulated in a notebook and kept for future reference, thus: Number of armature slots, 15; number of commutator bars, 29; coils spread slots 1 and 4; top leads throw 1 to 6 and 7 to the left; bottom leads throw, straight; leads spread, 1 to 15 (14 segments between); coils have 10 turns of No. 17 double-cotton-covered wire, and the wire weighs 2 lb. This last item can be determined by weighing the coils after they have been removed from the core. Any other information can be kept along with these items, such as insulation, time to rewind, cost, etc.

Before rewinding, clean the slots in the commutator bars so there will be no difficulty in getting the wires in and file the top and side, Fig. 6. Scrape in between the commutator bars to remove all carbon dust, also on the ends. Using a 110-volt circuit and lamp test between each bar and also each bar to ground, if the insulation is in good condition there should not be the slighest spark between bars when the 110 volts is applied. If there is a defect, even though it is on the surface of the commutator, scrape it away until it tests clear. Do not allow the test to burn the carbon deposits away on the surface of the mica, as it only injures the insulation.

If the commutator tests out clear, the insulation for the armature slots can be cut to size, so as to allow it to project by the end of the core about $\frac{3}{16}$ in. on each end, and about $\frac{1}{2}$ in. above the core; this will protect the wire as it is wound into the slots. It is preferable to insulate the slots with oiled linen and fiber in the form of a sandwich. For instance, suppose that the slot insulation used is 30 mils thick, make this up of 5 mils of oiled linen and two thicknesses of fiber each 5 mils; this will make 15 mils on each side of the slot, or a total of 30 mils.

In the armature under consideration the insulation as measured from a piece of the old material taken from a slot is found to be 10 mils in thickness, therefore it will be better to make this up of 5 mils of oiled linen and 5 mils of fiber, because if two pieces of 3-mil fiber is used it would be too thin to stand the handling of the wire and would break. The slots are 2 in. long by ½ in. wide and ⅝ in. deep, shaped elliptical. The insulation is cut 2⅜ in. long by about 3 in. wide. In addition to this small pieces of oiled linen will be required to place between the ends of adjacent coils as they are wound, thus increasing the insulation between them.

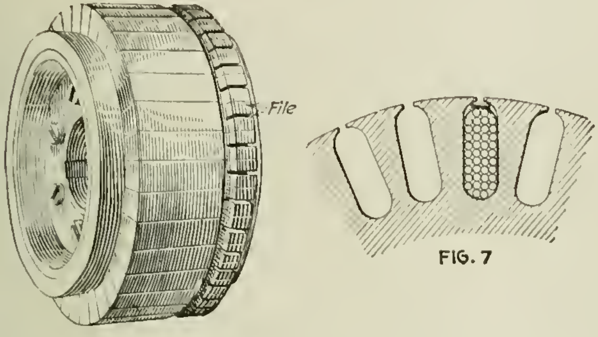

FIG. 6

FIG. 7

FIGS 6 AND 7. COMMUTATOR AND CROSS-SECTION OF ARMATURE SLOT AND COIL

Everything is now ready for the wire, and as the winding is four-layer, two wires can be wound together. To accomplish this, wind half the wire needed upon a second spool and then two wires can be wound into the same slot at once. Mark one of these spools No. 1 and the end of the wire coming from this spool with shellac or blue pencil; when the coil is completed, mark the other end to correspond. This will save a lot of trouble testing out when all the coils are in place. If No. 20 wire is used it would require four wires to be wound together and the wire would have to be wound upon four spools, marking two of them instead of one. It would not make any material difference which of the coils in the same slot came first, but it would make a difference if coils in two different slots were crossed. Begin at any slot, call this slot 1 and wind the first two coils in this and slot 4, then use the next slot and proceed until all are full, placing a piece of oiled linen in between the ends of the coils. Now cut the projecting insulation and turn back into the slot, pushing in a piece of $\frac{1}{16}$ fiber to cover and hold the wire in the slots, as this armature has no bands. A cross-section of one slot with the insulation and winding is shown in Fig. 7.

Looking up the throw of the bottom leads in the data taken from the armature, it will be found that they come out straight. Use the string to find the commutator bar that is opposite the slot started from, then bare the ends of the leads and place them in the commutator, leaving the top ones out. Get all the leads in rotation—that is, one marked and one unmarked lead all the way around the armature—then cover them with two layers of tape. When these leads are placed in the commutator, the ends will project out on the bars for about an inch, but do not cut them off short as it might be possible that some of these leads are twisted, and have to be changed. When the leads are being put down, interweave a piece of tape so as to properly separate each lead from its neighbor. When all the way around, one coil will be left over; this is the dummy coil already spoken of, and its ends must be found and cut off short. It is sometimes more convenient to place one or two coils in the slots and then put their bottom ends in the commutator instead of waiting until all coils are wound.

We are now ready for a test, and this must be made before the top leads are brought down to the commutator—first for rotation to see that no leads are twisted, then for shorts and opens. Arrange the top leads in the order that they come out of the slot and begin anywhere with the test lamp. Place one end of test circuit on the top lead and with other terminal find the commutator bar that the bottom end is connected to; this will light the lamp if there is no opening in the coil. Keep in contact with the top lead and touch the bar on each side of the one that the bottom lead connects to; no light shows no short-circuit between coils. Mark the bar which lights with chalk or anything else to identify it and place the test lead on the next commutator bar; a light should be obtained on the next top lead. Continue this all the way around. If any are crossed, make the correction on the bottom leads. Finally test for grounds; place one test lead on the core and with the other touch on each bar of the commutator. Next run a layer of tape over the bottom leads to make a nice even surface on which to lay the top leads, completely covering the ends of the coils, and begin to lay down the top leads. Select one top lead and find the other lead of this coil in the commutator, count toward the top lead 15 bar and place the top lead in this bar, and continue in rotation, making sure that none get crossed.

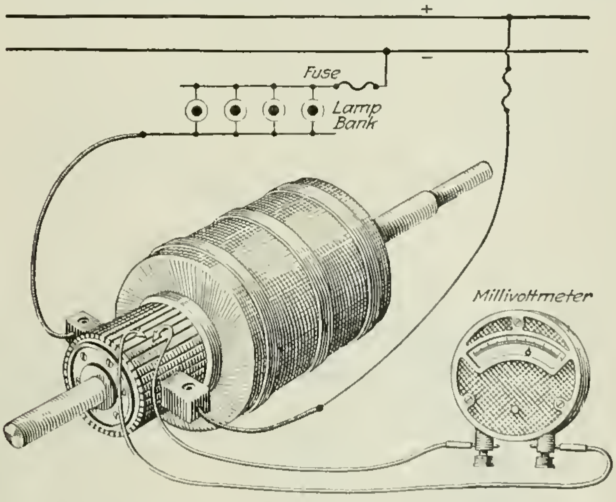

FIG. 8. METHOD OF TESTING ARMATURES

When all the leads are in place, hold them down with a temporary string band and place a little noncorrosive soldering paste on each bar and solder the leads in place. Raise the back end of the armature slightly to prevent the solder from running down the back of the commutator. Wash the commutator thoroughly with gasoline to remove all traces of soldering paste. Lastly, test with a millivoltmeter; the test can be made before or after the commutator is turned down.

With a bank of lamps in series, place two leads from the 110-volt circuit at points on the commutator where the brushes will rest when the armature is in place; that is, one-half way round for two-pole machine, one-quarter for a four-pole machine, etc. Pass a current through and measure the voltage between bars with a millivoltmeter; each reading will be the same if the work is correct (see Fig. 8).

Turn down the commutator and remove temporary string band on the leads and replace it with a permanent one. Place the armature in an oven until it is at a temperature of about 250 deg. F. for one-half hour, then remove and dip in or paint with clear insulating varnish and then rebake at a temperature of about 200 deg. F. for six or eight hours. This will make a very hard finish and warrant against the entrance of moisture or oil into the winding.

On parallel windings the procedure is somewhat simpler than that on series, as the leads of the coils are both brought together on one side of the coil because they are connected to adjacent commutator bars. All that is necessary is to use the string to find the throw of the leads, either to the right or left, and the spread of the coil in the slots. Usually, with small wires the coil is wound in, say, slots 1 and 4; then, instead of cutting a lead on the coil long enough to reach to the commutator readily, the wire is looped and the next coil immediately started. When the winding is completed, a loop is placed in each commutator bar; this will be the same as placing the ends of one coil in adjacent bars. The baking, etc., will be taken care of in exactly the same manner as for the series-connected winding described in the foregoing.

Portable "Chaingrip" Pipe Vise

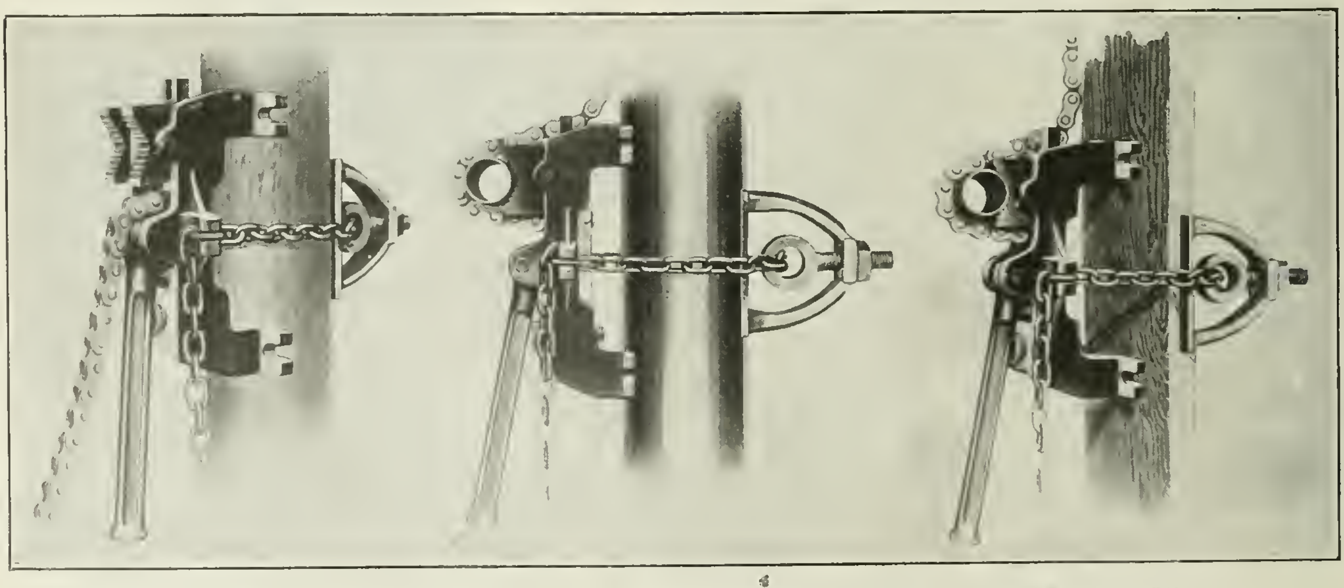
Most pipe vises are made to be permanently secured to a bench, and when the pipe has been threaded it must be carried to the point where the work is being done. Frequently, a portable vise bench is made, but it is not always convenient nor is it possible to move it to the point where it is wanted.

A portable vise known as the "Chaingrip," which can be easily and quickly removed from one location and mounted at another, is made by the Gerolo Manufacturing Co., Old Colony Building, Chicago, Ill. It can be fastened to any horizontal or vertical support, round, square or flat, without the use of bolts, and it locks any size of pipe or conduit within its limits by the slight push of a lever.

The base support of the vise is in the form of an inverted V, at the sides of which are bolt lugs to be used only in case the vise is to be permanently bolted in one position. It will therefore conform to a round, square or flat surface. A clamp support to fit on the opposite side of the column is a part of the equipment. The vise is clamped to any upright by means of a chain which passes through an eye-bolt that is part of the clamp. One end of the chain is riveted to one side of the vise base. After passing around the supporting column through the eye of the bolt, a link is held in position in a socket on the opposite side of the base. Screwing up on the eye-bolt nut tightens the supporting chain and holds the vise in position to the support, as shown.

The pipe or conduit is locked between a double set of steel pipe jaws on one side, and by a heavy close-linked steel chain on the other. The locking motion is accomplished by the downward movement of a lever. One end of the chain is riveted to one end of a horizontal bar which comes in contact with a cam on the lever end. The gripping chain passes around the pipe or conduit and is locked in a steel socket on the outer end of the base. The other end, or fulcrum point of the bar, is supported by a threaded bolt the enlarged knurled head of which rests upon a boss on the base of the vise. Rotation of the head of the bolt raises or lowers the fulcrum point of the bar and forms an adjustment of pressure exerted by the other end of the bar on the gripping chain when the handle of the vise is in a locked position.

The application of the vise to uprights is shown in the illustrations, also the method of attaching the vise and securing the pipe in place.



APPLICATION OF THE CHAINGRIP VISE TO SUPPORTS AND METHOD OF CLAMPING PIPE

Conditions in the Power Industry

BY LUDWIG W. SCHMIDT

A digest of the reports of the United States consuls on the power situation in the various parts of the world and the influence of the war upon this important industry. Also, see "Power," Dec. 11, 1917.

THE demand for electrical power is still very great all over the world. The principal reason, of course, is the industrial activity caused by the war. Secondary influences are the shortage of fuels used for power generation and in some cases their present high cost. The latter consideration, for instance, is responsible for an increased employment of electrical power in cases where gasoline was in use formerly.

Consul Franklin D. Hale reports from Huddersfield, England (C.R. 256)[1], that there is a great demand for electrical vehicles of all kinds throughout England. In some cities electric power has been adopted for omnibus service, and at many places power for commercial electrics can be had at the rate of 2c. per kilowatt-hour. A similar report is made by Consul E. Haldeman Dennison in Birmingham (C.R. 265).

The increase in the cost of coal has compelled additional expenditures in the budget of many electrical enterprises in England. It is reported (C.R. 273) that the Glasgow Corporation estimates an increase of $121,662 in the fuel bill of its electrical central station. The difficulties created by the increased cost of fuel for many of the central stations in England have made the last year a very unsatisfactory one, notwithstanding the fact that the kilowatt-hour output sold increased nearly everywhere. It is, therefore, interesting to note that the desire for a better organization of power distribution in England is gaining ground. Consul J. S. Armstrong, Jr., in Bristol, quotes in support of this contention, part of the engineers' report of the Bristol Electricity Department, where it is said: "It appears likely that in the very near future the organization of the electricity-supply industry throughout the country will be rearranged on a much broader basis than hitherto, the country being for such purpose divided into districts irrespective of municipal boundaries or the present limits of company-supply areas, and the generating stations of the future, being fewer in number, will be equipped with larger and more efficient machinery than at present in use" (C.R. 274).

In view of the great development of the hydro-electric power distribution expected in Italy as a result of the war, remarks made by Vice Consul Ilo C. Funk about the power situation in Milan are of considerable interest (C.R. 301). Milan today draws its electrical power from the Alps, where it is produced by hydro-electric plants. Power is distributed by the Societa Generale Italiana Edison di Elettricita and the Azienda Elettrica Municipale. Although both these enterprises have steam-electric plants in Milan, these stations are used only in time of drought. The energy consumed in Milan and adjoining towns is given as an average of 800,000 kw.-hr. per day, the maximum power demand varying from 56,000 to 70,000 kilowatts. Almost all the power is three-phase 42-cycle alternating-current transmitted at 8700 volts, only a limited quantity being 110- and 220-volt direct current used for lighting purposes in the central section of Milan. Two important power plants are now under construction—one at Sesto S. Giovanni, Province of Milan, belonging to Ernesto Breda & Son; the other in Milan, belonging to the Acciajerie e Ferrerie Lombarde. Both will produce three-phase alternating current and transmit it at 70,000 volts. The lack of fuel so prevalent in Italy has made necessary great economy among all those central stations using coal for generation. It is reported from Turin (C.R. 282) that the use of electricity has been restricted, in that city, by a decree of the prefect, resulting in a reduction of consumption of 50 per cent.

In Oporto, Portugal, a company has been organized to develop the water power of the northern part of the country (C.R. 271).

Denmark is feeling the effects of the war along with the rest of the neutral countries of Europe. The principal problem at present is the need of energy for lighting and power purposes. Denmark in this respect is rather unfavorably placed, as it has few hydro-electric possibilities. On the other hand, the proximity of Sweden, with its great hydraulic-power resources, has led to experiments to transmit power from that country to Denmark over submarine cables. This, in the case of several smaller villages in the north of Denmark, seems to have met with good results. The difficulty at the present time is, the power production of Sweden is considerably reduced during the winter months, and there has not been a sufficient surplus to continue a supply to Denmark during this period. With the increase of the Swedish power-producing facilities a better employment of part of the Swedish power reserves in Denmark should become possible. Commercial Attaché Erwin W. Thompson in Copenhagen reports (C.R.296) that additional cables will be laid across The Sound with the intention of furnishing power to the street-car service of Copenhagen and Frederiksberg. This power will come principally from the Laga Lakes and the Trolhättan Falls.

From the Gold Coast in Africa it is reported that the City of Secondee will be furnished with electric light by the Gold Coast Railway (C.R. 304).

Electrical development in New Zealand and Australia continues to be very active. Consul General Alfred A. Winslow writes that the City of Dannevirke intends to build an electric-lighting plant for its 6000 inhabitants (C.R. 264). Increasing attention is given to the use of electricity in the farming and dairying districts of the South Island of New Zealand. This is the country around Christchurch, and it is intended to erect a government hydro-electric station in that neighborhood.

Considerable activity in electrical development also is reported from all parts of the American continent south of the United States. Consul G. C. Woodward, Matamoros, Tamaulipas, Mexico, says (C.R. 262) that the

---

[1] C. R. indicates "Commerce Reports" of 1917

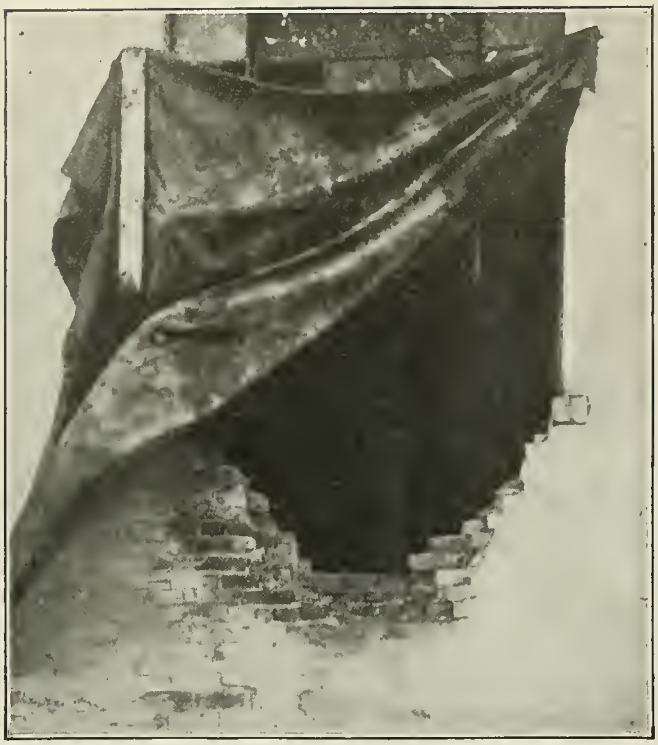


FIG. 1. WALL TORN OUT BY EXPLODED FLYWHEEL

only electric-lighting plants established in his district are at Victoria and Matamoros. The supply of electric light and power for public and private use is contemplated in Santo Domingo, Dominican Republic (C.R. 262). It is also reported from that republic that a franchise to build an electric railway in the City of Santiago de los Caballeros has been annulled. This would have been the first electric tramway in the Dominican Republic (C.R. 286).

Plans are under consideration in Guadeloupe, French West Indies, to build an electric railroad with a total length of track of 118 miles. The power will be obtained by harnessing two waterfalls, which are expected to supply sufficient energy (C.R. 275).

Consul Frank Anderson Henry reports from Venezuela (C.R. 275) that the South American Copper Co. at Aroa is engaged in enlarging its present small hydro-electric plant to about 800 hp. The City of San Felipe will have an electric-lighting plant, and it is further contemplated to furnish Barquisimeto and Yaritagua with electricity generated by a large waterfall near the latter city. Barquisimeto has already a small plant using anthracite for fuel. This, however, supplies light only at night. The war has brought a considerable weakening of German influence in electrical enterprises in South America. It is reported that the Compania de Tramways Electricos del Sud, of Buenos Aires, Argentina, has not renewed its power contract with the Compania Alemana Transatlantica de Electricidad, which is a German company, but has made arrangements for a power supply from the new Compania Italo Argentina. The income of the tramway company shows a falling off, and the operating expenses have increased (C.R. 234).

Interesting information as to power development in Peru is contained in a special report by Consul General William W. Handley, Callao, Lima (Supplement C.R. 46a). This report shows that the service provided by the Lima Light, Power and Tramways Co. has increased considerably with good effects on the income of that enterprise. This increase is due especially to the growing of general industrial activity in and around Lima, which holds good promise of a further extension of power demand in that city and its neighborhood.

Flywheel Explosion at Minot, N. D.

The photographs reproduced show some of the havoc caused by the failure of a flywheel on a direct-connected reciprocating-engine generating unit at the plant of the Northern States Electric Light and Power Co., Minot, N. D., at about 3 a.m., Oct. 17, 1917.

The night engineer was instantly killed and a large amount of property damaged. Fragments of the wheel went through the window and the brick wall below it, as shown in Figs. 1 and 2, rocketed a full city block (about 500 ft.), striking a newly erected brick building which was unoccupied except one apartment on the top floor, into which a piece of the wheel was driven, causing the damage shown in Fig. 4. Fortunately, a larger engine, set at right angles with its shaft almost in line with the flywheel that failed, was not running or greater damage no doubt would have resulted, as several large pieces of wreckage were found in its wheelpit, and some wreckage may be seen near it in Fig. 3.

A curious feature was the damage to a box-car and the tearing out of two rails from the main track of the Great Northern Ry. The "Oriental Limited" was about due, but was flagged in time to avoid a wreck. The city was without light until the débris was cleared away and numerous repairs made to the damaged plant.

Average and Maximum Heating Demand

By M. W. Ehrlich

In heating work it has become an established custom to design plants to provide a temperature of about 70 deg. indoors when the minimum outside temperature is zero, but during the season the outside temperature may be as high as 65 deg., when but little artificial heat is needed. This range of outdoor temperature corresponds to conditions in the Middle Atlantic states; elsewhere the minimum outside temperature may be considerably above or below zero, therefore the local weather bureau records should be consulted to learn the lowest temperature. However, it is customary to base calculations for average conditions for the range from zero to 70 deg. In many localities zero weather may not be reached except in January and February, and then only during the early hours of the morning, just after midnight, lasting for periods of not more than about three to four hours at a time during the entire season.

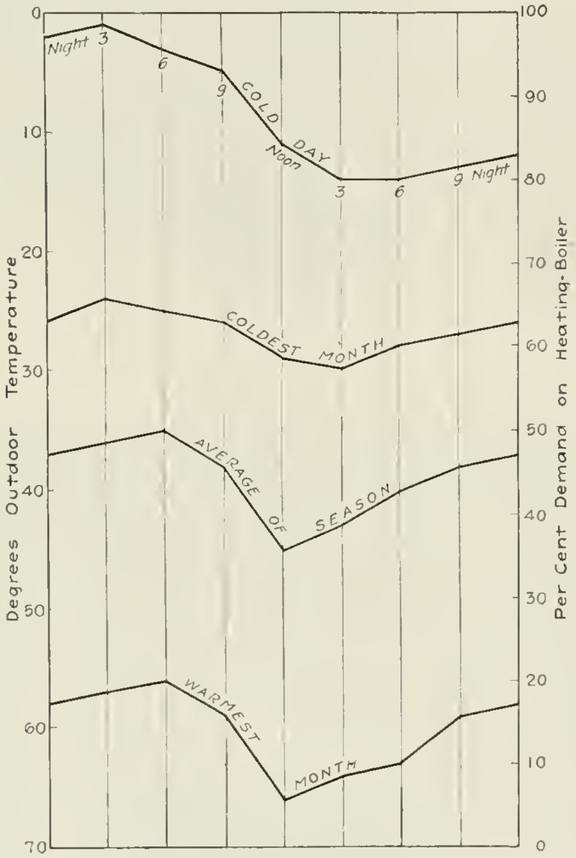

FIG. 1. TYPICAL TEMPERATURE-FLUCTUATION CHART

The maximum demand for heat therefore obtains only for very short periods. The average requirements for the locality referred to are given graphically in Fig. 1, which shows the typical fluctuations in outdoor temperature during a day in the coldest and the warmest month and for the entire heating season. The scale at the left gives the temperature in degrees, and the scale at the right is assumed to be the corresponding tax on the boiler plant to supply the required steam. The curve of the "warmest month" might represent April, while the "coldest month" might be January or February. In the first case the boiler would be taxed an average of about 15 per cent. of its capacity, while in the other case the average monthly demand is about 62 per cent., and for an "extremely cold day," the minimum temperature is nearly zero during the night, gradually rising to about 14 deg., averaging about 9 deg., taxing the boiler during that day to about 87 per cent. of its capacity. The average temperature for the heating season in New York City is about 38 deg., requiring approximately 44 per cent. of the assumed maximum boiler capacity.

The amount of coal or steam, which is the tax on the boiler, therefore is a proportionate variable of the outdoor-temperature fluctuations, and on this basis, using zero temperature as a maximum demand, diagram Fig. 2 has been prepared for average conditions in New York and vicinity or other localities having similar climatic variations during the heating season. It is intended more as an illustration of how such diagrams are constructed and used than as a standard of computation. As an example it should serve its purpose well.

The load curve, shown shaded, may represent the amount of coal or steam or boiler tax for each month. The scale at the left is given in percentage for convenience, as in that way a relative value is at once established regardless of the unit and numerical value selected. The monthly coal requirements are expressed in percentages of the total used during the season. For example, during December 18.2 per cent. of the coal used during the entire heating season will be consumed, while in April only 9.8 per cent., showing that considerable coal is wasted because the boiler drafts and radiators are not controlled in conformity to the weather variations, but with automatic temperature regulation and draft control the steam demand would correspond closely.

Keeping a Record of Outside Temperature

A monthly check on the coal consumption is conducive to operating economy. For a given locality it is therefore necessary to construct a diagram similar to Fig. 2, which would take the local weather conditions into consideration. By keeping a record of the outside temperature, either through personal observation or by watching the newspapers if there is no local weather bureau, the essential information may be obtained. It is useful to record at least the average daily temperature on the power-plant log sheet. Some engineers note down in addition the maximum and minimum outdoor temperatures. Then, according to the records, taking 70-deg. temperature difference as a basis, the average temperature for November is, say, 43 deg.; then 70 less 43 gives 27 deg. difference, and dividing this by 70 equals 38.6 per cent. Likewise in January the average is, say, 25 deg. and the difference is then 70 — 25 = 45, which divided by 70 gives 64 per cent. In the same way the relative heating demand for each month is determined and plotted. It should be noted that the divisor is the maximum or basic temperature difference, which represents 100 per cent. From the values found as shown, the average of the season is computed as well as the relative monthly coal requirements.

The actual quantity of coal required for a heating system is dependent on the variables heretofore noted, and for a particular installation the local physical conditions must also be known. This would mean the total or equivalent square feet of direct radiation in the building, the number of hours the system operates during the heating season and the grade of coal burned. The computation for the tons of coal required for the heating system during the season is:

$$\text{Tons of coal} = \frac{\text{sq.ft. radn.} \times \text{hours operation} \times 300}{\text{heat in coal} \times 2000 \times \text{efficiency} \times \text{average demand}}$$

This computation may be simplified for practical application as follows, so that the result will be the tons of coal approximating fair operating conditions. The variables are well accounted for in the fact that there are losses when fires are banked and cleaned and that the draft control does not correspond exactly with the weather variations. These variables comprise the useful heat in the coal, the over-all efficiency and the average heating demand.

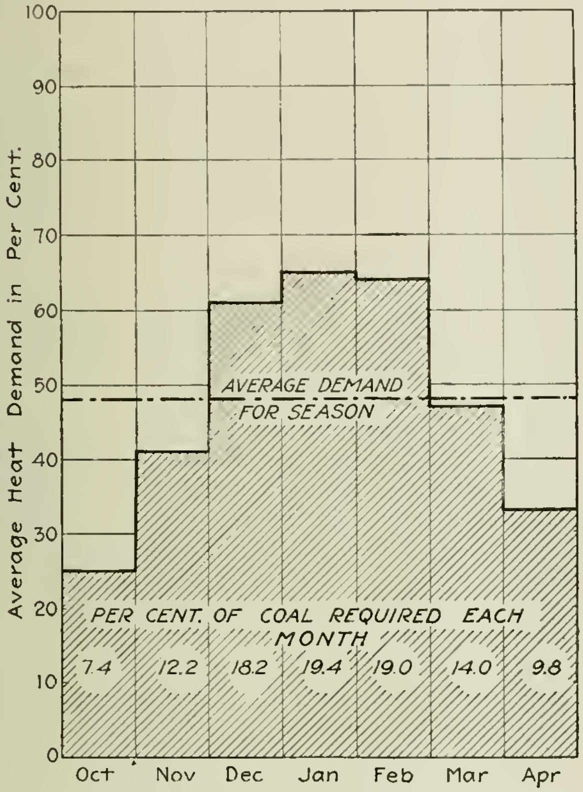

FIG. 2. SEASON'S MONTHLY AVERAGE TEMPERATURE

The average demand on the system for the entire heating season is a value that must be determined for the particular locality in which the plant is situated, as it depends on the weather variations and may be arrived at in the manner explained in connection with Fig. 2.

Taking all these variables as one combined whole, the component may be designated as a factor to be used in the simplified formula. This factor would naturally vary for different localities because the weather conditions give a different average demand on the system. It would also vary for hard- and soft-coal operation because of the characteristics of these fuels. Then, for observed averages of operation and heating demand in steam plants using hard and soft coal, the values for this factor may be computed for different localities. The numerical values of this complex factor so computed have been designated as *f* and are given in the tabulation herewith.

TABLE GIVING VALUES OF FACTOR (*f*)

Location	Hard Coal	Soft Coal
Boston, Mass	85	80
Columbus, Ohio	84	78
Detroit, Mich	89	83
New York, N. Y	70	73
Philadelphia, Penn	75	70
St. Louis, Mo	64	60

These values, when used in connection with the following formula, give a close approximation of what the coal consumption should be under fair operating conditions. The factor *f* may therefore be said to represent the tons of coal used per hour during the heating season for each square foot of radiation for a given locality when applied specifically to the formula which gives the total tons of coal required for the heating season as equal to:

$$\frac{\text{Sq.ft. radiation} \times \text{hours} \times f}{10{,}000{,}000}$$

Consider for example a shop running 24 hours a day for 200 days in the vicinity of Boston and the installation consists of several indirect radiators, pipe coils, and many regular cast-iron radiators, aggregating an equivalent of 2380 sq. ft. direct radiation. What will be the coal consumption under this condition? According to the foregoing the computation is as follows: 24 hours times 200 days gives 4800 hours as the total operating time. The average demand corresponding to *f* is 85 for Boston, when anthracite coal is used. Then, tons of

$$\text{coal} = \frac{2380 \times 4800 \times 85}{10{,}000{,}000} = 97.1 \text{ tons.}$$

Then with 97 tons required for the heating season, the monthly use of coal can be determined as has been shown, but it is a variable corresponding to the weather and not a direct fractional proportion of the total months in the season. Assume that this condition corresponds to the load diagram, Fig. 2. It will be seen, for example, that for the month of December 18.2 per cent. of this total, or about 17.7 tons of coal, will be required. In the same way it is found that during the month of March 14 per cent. is consumed, which is equal to about 13.6 tons.

Determining the probable coal consumption by the method outlined, gives a means of comparison, for if the actual coal consumption for any month exceeds the quantity as computed for the weather conditions and temperature differences, then apparently some coal has been wasted. If the difference is quite small, it may be just a variation due to averaging, but if there is a wide discrepancy, the conditions justify an investigation so that the same leak or waste will not occur or appear again.

This method of computing the coal consumption will be found to agree closely with practical conditions, and as a means of checking the operating efficiency of the plant it will be found helpful. Engineers who keep plant records or log sheets usually know what the total coal consumption is for the entire plant and equipment. Deducting the coal required for the heating system gives a remaining quantity that shows the other useful service the coal has given. If this figure is too high for the load carried, something requires attention and the sooner this waste is found and things set right the sooner will the over-all efficiency begin to pick up.

A Traveling Anti-Waste Exhibit

In a large manufacturing plant where thousands are employed, it is surprising to learn of the food products and manufacturing material wasted each day.

To give the employees of the Westinghouse Electric and Manufacturing Co. some idea of the waste, the management devised the idea of fitting up a storage-battery truck as a traveling exhibit and upon it a collection of food wasted, including bread, butter, meat, cakes, crackers, pickles, cheese, fruits, etc., as well as a quantity of manufacturing materials such as copper, zinc, lead, mica, rubber, felt, gum and similar materials, much of which could be used to advantage.

It is estimated that the foodstuffs wasted every day amount to between $35 and $50, the cost of which, of course, comes out of the employees' pockets; the waste of material amounts to hundreds of dollars per day—which would be a loss to the company if it were not that a force of men are continually assorting the seemingly scrap material and turning it back for use or so that the highest price may be obtained for scrap produce—all due largely to the carelessness of the employees.

A TIMELY OBJECT LESSON

Above the material is a sign reading in large letters, "Wasted"; and underneath the words, "Food Brought from Your Homes"; and on the other side, "Material Belonging to the Company."

This truck was driven up and down the shop aisles so that the employees could look upon it and form in their minds some idea of the waste. Such an object lesson is valuable at this time, when everyone should reduce waste as much as possible.

Fuel Saving "Don'ts"

To assist the Fuel Controller for Canada in his campaign for fuel conservation, the General Accident Assurance Co. of Canada has prepared the following series of "don'ts," which have been printed and are being distributed to manufacturers and boiler owners:

1. Don't fill the furnace with the intention that there will be no necessity for any additional fuel for the next two to four hours. This is quite a common practice with heating boilers, and with bituminous fuel results in very great waste.

2. Don't regulate the draft by closing the ashpit door, but regulate it with a damper in the smoke flue or pipe between the boiler and the chimney. This also applies to any kind of furnace.

3. Don't allow any cracks in the brick setting of the boiler, because cold air will enter through these cracks and absorb the heat that should have been transferred to the boiler.

4. Don't permit the use of grates of any kind which are in bad condition. This will permit the unconsumed fuel to fall through to the ashpit and be shoveled out as ashes or waste.

5. Don't use a grate that is larger than will permit the burning of at least 12 lb. of coal per square foot of grate per hour.

6. Don't permit any pipes or boiler surfaces to remain uncovered, unless it is necessary to transmit the heat through the surface of that pipe to the room in which it is located.

7. Don't permit any joint in the boiler or any pipe connected thereto to leak.

8. Don't permit any valve to leak which is located on a pipe supplied by the boiler. This is a very common source of loss. All valves should be positively tight when closed.

9. Don't attempt to control the quantity of condensation to be collected from any pipe or other apparatus by hand control. There are many good serviceable traps to collect these returns of condensation and they should be returned from these traps to the boiler.

10. Don't permit any surface on the boiler exposed to the furnace heat to become covered with soot or ashes. The tubes should be cleaned at least daily.

11. Don't use live steam for heating rooms, liquids or other substance when there is exhaust steam from engines or pumps available. If the exhaust steam is not of sufficient temperature to heat the room, the liquids, or other substance to the required temperature, arrange your heating to be done in two stages; for instance, water could be heated to nearly 212 deg. F. by exhaust steam, then passed through to another vessel to be heated to the desired temperature with live steam.

12. Don't feed a boiler with cold water when there is exhaust steam available to heat it. Every eleven degrees in temperature that feed water is raised by heating by exhaust steam there is a saving of 1 per cent. in fuel, and in wintertime especially feed water is very seldom any warmer than 42 deg. F. If this water is heated to 212 deg. F. it will then effect a saving of 15 to 16 per cent.

13. Don't allow the main steam valves on any engine or pump to leak. This is a very common fault, due to the fact that the leak is not seen.

14. Don't allow the piston of any engine or pump to leak. This is also a common defect permitted to go on day after day simply because the leak is not seen.

15. Don't take it for granted that pipes that lead to sewers, blowoff tanks or other places of discharge are tight. If the pipe is warm between the stop valve and the source of discharge, it will generally pay to investigate a little closer, because it generally is a sure sign of leakage, with great waste.

Use Surplus Productive Power To Rehabilitate the Railways

THERE are indications on all sides that we are approaching an industrial and economic crisis. One of the most evident signs of this is the amount of criticism which is being showered on those in charge of Government activities, nearly all of which at present relate to the war. The attempts to blame these various inefficiencies on individuals are being made on all sides. It was only natural in this confusion that Army officers and Government officials in general should be the first to receive the blow, for we have always held the theory that Government officials were far more inefficient than our business men.

The number of applications from private manufacturers for the help of "efficiency engineers," which has so largely increased lately, is indicative of a realization on the part of many of our manufacturers that their methods also are not what they should be. The people who are applying for help are in many cases no worse off, as far as their methods are concerned, than others who have not yet discovered how badly they are doing their work. The whole subject seems to resolve itself into the fact that our business and industrial systems are not suited for times like these, when it is necessary to combine all our energies and exert our full driving power toward the achievement of one supreme object.

We should not be surprised that this is the case, for our economic theory has never contemplated teaming up all the industries of this country for one object, but has rather discouraged that idea and encouraged individual competition of the most strenuous kind. In other words, we are a nation of individualists who have never really seriously contemplated coöperation for the common good.

When this problem of coöperation is suddenly put up to us as it has been by the war, it is not surprising that our business men, trained in the individualistic school, should be entirely unfitted to solve the new problem. Moreover, it might be expected that the men who have been most successful in individualistic, competitive business, in which profit was the main aim, should be actually the ones least fitted to establish a scheme of business and production for the benefit of the community. This is a new problem to them, and one altogether outside of their experience.

It is to be granted that such business men may have individually great driving power, but this very excess of driving power in individuals or corporations is likely to make the confusion all the worse, unless a means of coördination is established which will keep the driving power of the individuals or corporations in proper balance.

It has become perfectly evident to all observers that the capacity of the nation for production of war material is enormously greater than its capacity for shipping it to Europe, and that we must at once not only balance this production, but slow it down in order to prevent such a choking of our Eastern ports as may produce an impossible condition. The five-day shutdown ordered by the Fuel Administrator and the one day per week shutdown are our first attempts to slow up this production, and we ask ourselves at once if this is the best way. The answer comes that if we are making too much war material we had better turn such of our activities as cannot be utilized in increasing our shipping capacity into the manufacture of articles of peace. Immediately we run into the financial situation, which at present seems to seriously hamper new undertakings.

It would seem that the claim of the railroads that they need $1,000,000,000 worth of improvements should at this juncture be considered. Here is one organization now devoted exclusively to the service of the community, which, being under the control of the Federal Government, can be financed directly by that Government, and there would seem no reason why the production programs of war material should not be limited, and a certain amount of the energy now being expended in that direction turned at once toward the improvement of our transportation facilities.

Our Fuel-Oil Supply

NATURE has been prolific in her provision of fuels for the benefit of man. The potential energy locked up in the interior of this planet of ours is enormous. The world's coal reserve, according to a recent estimate, is roughly 7,397,553,000,000 tons. Miners are cutting into the supply at the rate of about 1,500,000,000 tons per year, or less than two-hundredths of one per cent. In all probability the estimated amount of the world's coal reserve is much below the actual figures given, since coal is occasionally found in territory yet unexplored and in localities where its existence was not previously suspected.

The present world conflict has accentuated the demand for liquid fuel to the extent that the magnitude of our petroleum supply is one of the questions of the hour. The present demand for petroleum is in excess of production, in spite of the fact that over three hundred million barrels was marketed in the United States alone in 1916, and the estimates for 1917 and 1918 are 319,000,000 and 338,000,000 barrels respectively. Since the United States in normal times produces approximately sixty-five per cent. of the world's petroleum, we may expect a petroleum consumption for 1918 of over half a billion barrels. With the consumption increasing at the rate of six per cent. each year, we have a right to be somewhat concerned about the source of our future supply.

Where is the oil to come from? Unlike our coal resources, we have no means of estimating the contents of the oil sands below the earth's surface. Whether our oil reserve is being rapidly depleted or not, we have no means of telling. We may be fast approaching the limit, or we may be just scratching the corners off, as in the case of coal. This refers to our supply of oil from wells.

The history of the petroleum industry would tend to make our forecast optimistic in a way, while the general tendency is toward the pessimistic view. This attitude is caused more by the habit of jumping at conclusions than basing our decisions upon actual facts. We have it as the opinion of one well informed in the oil industry that there are possiblities of new fields in every state in the Union. It is a matter of fact that oil is often discovered in most unexpected places. Localities that are considered today as of no importance in the oil industry may, a few years hence, be pouring out a flood of oil.

This statement is substantiated by numerous examples. The production of the Kentucky oil fields was in the front rank for November, 1917, yet about a year ago this state stood at the bottom of the list. Wyoming is fast becoming an important factor in production. While six years ago its output was of practically no account, today it is giving us about five million barrels a year. But the rise of Oklahoma as a producing state was, perhaps, the most spectacular. In 1906 its production was so small that it was included with that of Kansas; in 1915 Oklahoma passed California and stood in the front rank with a production of nearly ninety-eight million barrels, which was 34.83 per cent. of our total production. This would give a reasonable foundation to hope for the discovery of new fields from time to time as the demand increases the incentive to search for them.

Leaving our own shores, we find that there is much potential oil territory in many parts of the world. China, for example, promises much for the future, although the present production in that country is small. Oil territories are being exploited in Australia and New Zealand. Many parts of South America hold out promises; for example, the oil fields of Argentina and Peru are already of considerable importance.

Passing from the oil well as a source of supply, we have within our borders another source of this valuable fuel, of almost limitless extent, as yet untouched. Unlike the oil from wells, it is possible to estimate the extent of this supply. Covering 100,000 acres in northwestern Colorado and extending into the neighboring states of Utah and Wyoming, there is practically a whole mountain range of bituminous shale, rich in oil. The sides of the precipitous cliffs in this region show layer upon layer of rich oil shale. A careful survey of this region, by representatives of the United States Geological Survey, indicates a deposit of petroleum in Colorado alone, of at least twenty billion barrels. Comparing this deposit to the output from oil wells, it is found to be nearly three times the total production of petroleum in the world from the beginning of the industry in 1857.

Analyses of the oil distilled from this shale show it to have a paraffin base and to be of most excellent quality. Chemical engineers state that it shows a gasoline content as high as 25 per cent. It carries valuable byproducts, chief of which is ammonium sulphate. The value of this one byproduct is sufficient to pay almost half of the cost of extracting and refining. So valuable are these deposits considered by our Government that the President on December 6, 1916, set aside forty-five thousand acres, or nearly one-half the Colorado shale-oil field, as a fuel reserve for the United States Navy.

There is nothing difficult about extracting oil from shale. The shale-oil industry has been a profitable enterprise in Scotland since the early fifties, and the output of oil from Scotch shales today is approximately two million barrels per annum.

But we need not stop here in our estimate of the liquid-fuel reserve. More or less oil shale has been discovered in many other states. In many parts of Ohio and Indiana, oil-well drillers penetrate a strata of dark brown shale, about one hundred feet above the Trenton sand. From the best information obtainable, this is a deposit of oil shale which it may pay us to mine some day, as is done in Scotland. We recall having seen the statement by one of our Government geologists that, in the oil shales underlying Ohio and Indiana, there is sufficient oil to fill Lake Huron. It would appear from this brief statement that we have no cause for alarm as to our oil supply for the immediate future, whatever the situation may be a generation hence.

Not Developing the Water Powers

In view of the fact that some 60,000,000 horsepower is continuously going to waste in the streams of the country, it is beyond comprehension why an enlightened people like ours should not only fail to encourage, but should blindly bar the way to the development of a great natural resource so important to the well-being of the nation. When we consider the benefits which have already accrued to industry from the water powers now developed and recall how we have besought, appealed and pleaded for legislation to permit further development, we contemplate the present unhappy power situation with pain and sorrow. How the cry for power must strike with hollow mockery the ears of the water-power obstructionist!—*Exchange.*

The data show that 120 out of about 1500 public-service corporations claim to own or control a total of 3,683,000 undeveloped water horsepower, or 80 per cent. of the total water power at present developed by public-service corporations.

Those who lay claim to such extensive ownership or control of undeveloped power sites are hardly in a position to contend that any legislation or lack of legislation or any administrative policies of the executive departments of the Government should be held responsible for the stagnation in water-power development which they allege exists. The fact, if it is a fact, that a comparatively few corporations hold unused nearly 4,000,000 water horsepower would of itself furnish sufficient explanation. — *O. C. Merrill, Chief Engineer, Department of Agriculture.*

Garabed Giragossian has appointed a commission satisfactory to Secretary Lane, to pass upon the merits of his alleged invention whereby unlimited power is to be gathered from a new source. In case he demonstrates to the satisfaction of the commission that he has anything, the Government has the free use of it, but guarantees him in the control of all other uses of it for seventeen years. In case he doesn't satisfy the commission—Oh, well!

All that one does in his lifetime that really counts is done in a short number of hours. The rest of the time is consumed in getting ready and in waiting.

Correspondence

The Administration's Water-Power Bill

The twelve-year fight to keep the nation's water power from capture by the power monopolists is at last on the verge of being won. The Administration water-power bill now before Congress opens the way to save for the people of the United States their most valuable natural asset. Some fifty million water horsepower is at stake. The bill in question was formulated under the direction of the Secretary of Agriculture, the Secretary of War and the Secretary of the Interior, was submitted to the President for his approval and recently put forward as an Administration measure. It deals with water power in national forests, public lands, Indian lands and navigable streams. A special committee of the House has been created to consider it.

It is an admirable measure, drawn with thorough knowledge and unusual skill. The principles essential for the wise use and development of our public water powers in the public interest are all embodied in it.

I have always urged the support of the following seven definite principles in water-power legislation:

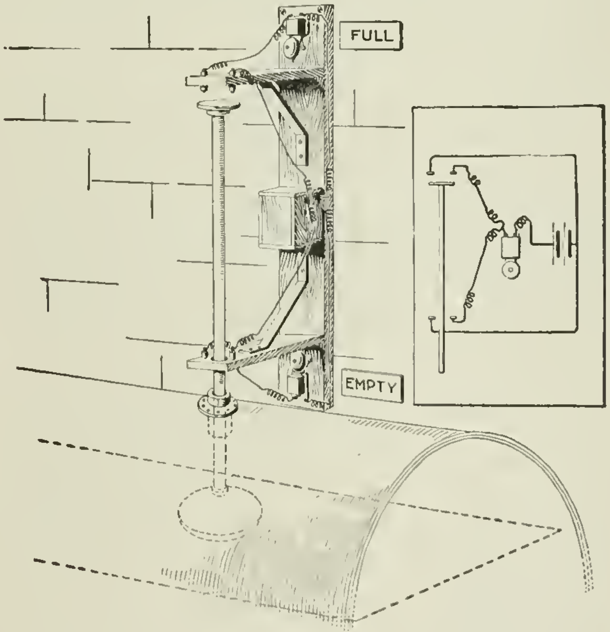
1. The thing to do with water power is to develop it. Whatever retards or restricts the development of public water powers on terms fair to the public is against public policy and hostile to the general welfare.
2. Water power belongs to the people. The sites where it is produced should always be held in public hands, for only so can effective control in the general interest be secured.
3. Where public development is not desired, the right to use water-power sites should be leased for periods long enough to permit sound, attractive and profitable investment, but never longer than fifty years. At the end of each lease all rights should return to the people who gave them.
4. In order to protect the consumer against extortion, rates and service should be regulated by Federal authority when state or local authorities fail to do so.
5. Reasonably prompt and complete development and continuous operation, subject to market conditions, should be required. Already millions of water horsepower are held out of use to further monopoly by private corporations.
6. Corporations or individuals that make money out of rights granted by the people should share their profits with the people.
7. The public has a right to complete information about every business based on the use of public property.

It is a real pleasure to know that every one of these principles is fully safeguarded in this bill. What remains, therefore, is for Congress to put this measure through without delay. The Administration water-power bill will first come before the House of Representatives, where an effort will certainly be made to amend it in the interest of the power interests. If that fails, the water-power lobbyists will endeavor to have the indefensible provisions of the Shields bill substituted in the Senate for the Administration bill. Beaten in that, they will fall back upon the formula of obstruction and delay they have used so successfully for the last ten years. This measure is practical, fair and wise. The friends of conservation should insist that their friends in Congress shall give their prompt and full support to the Administration bill and shall see to it that it is passed without emasculation, substitution or postponement. It is of vital interest to our country while the war is on, and will be equally important after the war is over. The passage of this law will secure to the American people forever vast resources whose use for the good of all will make this land a safer and a better place to live in. All the forces of conservation are behind it. I urge you to give the bill your strongest approval and support.

Milford, Penn. GIFFORD PINCHOT.

High- and Low-Water Alarm

The illustration shows without the need of much explanation a device for ringing an alarm bell when the water in a tank is high or low. As the water and the float lower, the cross-piece or disk on the end of the rod completes the electric circuit at the contacts, which causes the alarm bell to ring. When the water rises to a predetermined point, contact will be made at the other terminals and the high-water bell will ring, giving notice that it is time to stop the pump. Two bells are shown, but both of the contacts can be connected with the same bell if desired. D. R. HIBBS.

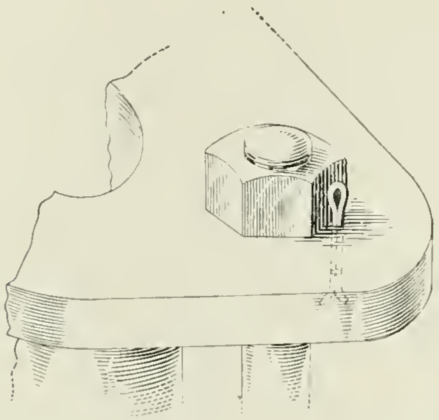


FLOAT-OPERATED HIGH- AND LOW-WATER ALARM

New York City.

Securing Gland Nuts

The valve-stem stuffing-box gland nuts on Corliss engines often give trouble by working loose and allowing the packing to blow out, requiring a shutdown to repack. This is more often the case on old engines that have worn valve stems having a side movement, every time the hook picks up the steam arm, which tends to move the gland and work the nuts loose. There is sometimes scant room on the studs for the jam nuts, so the engineer has to keep a close watch on the single nuts to keep them tightened. While overhauling recently, I drilled a small hole in each end of every gland in such a position that a small cotter pin inserted in the holes acted as a nut lock. This is also a good kink to use on the piston-rod glands of big engines and may prevent a serious accident. J. W. Stanley.



COTTER PIN TO KEEP NUT FROM TURNING

Braemar, Tenn.

Power-Plant Burns Locomotive Sparks

My attention has been called to an article in *Power*, page 13 of the Jan. 1 issue, descriptive of a large electric power station in Germany wherein locomotive cinders are burned under the boilers. It is said to be "the first large railway power station in the world to be operated entirely on cinders taken from the locomotive."

It may be of interest to recall that twenty years ago the New York, New Haven & Hartford R.R. built three power stations, from 500 to 2500-hp. capacity, in which horizontal return-tubular boilers were fitted to burn this same kind of fuel. Most of this work, both construction and operation, was under the immediate supervision of the writer who, at that time, contributed an article to *Locomotive Engineering* in which it was described fully.

To most railroad men locomotive cinders are known as "sparks" and are, of course, small pieces of partly burned coal, which is really coke, drawn through the tubes by the exhaust and confined in the front end by the screen, from which they are dumped at the end of each trip. A number of experimenters had previously discovered that sparks could not be successfully burned by the use of the ordinary forced draft under the boilers unless mixed with coal. Success was obtained by the use of a forced draft in which steam is mingled with the air blown into the ashpit. A steam blower fitted to the ashpit doors supplied this combination. The hydrogen of the steam combined with the carbon of the sparks, forming what is commonly known as water gas. The boilers were set high above the grates, forming a large combustion chamber; they were hand-fired and not overloaded.

No coal was ever mixed with the fuel except on rare occasions when a heavy load dropped the steam pressure seriously. For eight or ten years, at least, to my knowledge two of these power stations were operated entirely by sparks.

Shortly after they were in operation, a number of European engineers and railroad officers (some Germans among them) were on a tour of this country and were being shown the boiler room of one station. Mr. Aspinwall, then general manager of the Lancashire & Yorkshire R.R., was closely examining the sparks and also the ashes. Holding a small portion of each in his hands he remarked: "Do I understand that you have already burned this stuff in your locomotives, and you are burning it over again here?" I replied, "That is so." "Then," said he, "pray tell me who burns it after you get through with it?" Edward C. Boynton.

New York City.

A Smokeless Portable Forge

A small forge is a handy device about a steam plant, but it has one disadvantage—it will fill the room with smoke unless there is a smoke connection to the outside, which is not commonly the case. Much of the smoke can be avoided by arranging the forge as shown in the illustration. I used a common forge with the hood attached, and connected at the top, at D, a tin pipe of the same size as the opening into the intake side of the blower B, as shown at C. When the blower is in use, the smoke that rises from the fire is drawn up into the hood in the direction of the arrows and down to the blower, which forces it up through the fire without its escaping into the open. J. A. Lucas.

Piston Packing Burns Out

In reply to Mr. Noble's letter on page 129 in the issue of Jan. 22, I would suggest that he look over the oiling system and make sure that the proper amount of oil is reaching the cylinder at all times. If, as he states, the material and workmanship are of the best, I am inclined to think the heating of the rod is from undue friction caused by the stoppage of the oil supply—perhaps for a short time, but long enough to permit overheating. J. H. KENDEL.

Chicago, Ill.

I believe it may be caused by any one of several reasons. The rod may be too small and at times of peak load may spring, thereby throwing excessive pressure on the packing. This might occur and yet not show in the packing for some time afterward, but the most probable cause in my opinion is in the packing itself, although Mr. Noble assures us he is using a good grade of packing and backs it up by the statement that it cost $1.50 per pound, but that is no proof that it is adapted to his special need.

Twenty-five years of engineering experience has taught me that packing can cause any amount of trouble and worry, yet I do not think that we can recommend any one brand or make that will suit all places or conditions. In former years I made many changes and tried every new packing that I could get hold of, but now I use but one make and have no packing trouble.

Syracuse, N. Y. M. E. WEBBER.

I almost "sweat blood" over an experience similar to that described by Mr. Noble, shortly after taking charge of a Corliss engine plant. The coal consumption was enormous for the size of the plant, and after setting valves and testing for leaks, I opened the boiler and found it badly limed. After cleaning by mechanical means as much as possible, I started a heavy treatment of soda ash and hydrated lime. Then trouble with piston packing began with evidences of lack of proper cylinder lubrication. We fixed up an oiler for the piston rod and did considerable fussing with the lubricator, but to no avail. It finally occurred to me that the trouble was greatest when the engine was heavily loaded; then came the inspiration, the boiler was foaming! That was easily remedied, and we had no more trouble on that score.

The next day we cleaned the boiler and, before refilling, put in a gallon of kerosene to float upon the water and soften the scale. Shortly after starting up, the steam valves would not close until pushed down by the hooks and there was a strong smell of hot kerosene around the engine; so it was surmised that the kerosene vapor had washed the oil off the valves. After getting rid of the kerosene via the safety-valve route, the engine valves acted properly and the packing did not heat.

By the way, the real cause of the foaming was a worn-out blowoff valve that we were afraid to use often enough. HOWARD WOLCOTT.

Ponca, Neb.

I have had the same kind of trouble as that described by Mr. Noble, on an Ideal engine, and it seemed to be caused by the packing expanding excessively. I now pack the piston in the usual way, drawing up the gland nut with a wrench and then backing off. As we only run ten hours a day, I back off the packing nut every morning until I feel that it is not tight, after which I do not touch the gland until I hear it blowing, when I repack the piston. I have only had trouble with one brand of packing, and with this brand it does no good to draw up on the gland after blowing begins. W. G. WALTERS.

Aurora, Ill.

I think the packing gland is too tight after the new packing has been put in, and for a day or less Mr. Noble should back the gland nuts off till steam starts to blow, then take up enough to stop it; and the next day try to back off some more. In the meantime he should have a small pail of cylinder oil and graphite (there should be enough graphite to make it thick) and every three or four hours for a few days give the rod a good coat of this mixture; then after three or four days, two or three times a day will be enough. He should try this treatment on any rod and see how much longer the packing will last and what a good finish it will put on the rod. FRANK WELLS.

Jeffersonville, Ind.

The trouble with ordinary "soft" packing (no matter how good the quality may be) is that when adjusted with the gland nuts just set to hold the packing in place—say finger-tight—the steam works in behind the packing and exerts a force in exactly the same manner and with the same effect as if the packing gland nuts were drawn too snug, and overheating follows. On the other hand, if the gland nuts are drawn so tight that the steam cannot get behind the packing, it will pinch and the rod will heat. My suggestion as to a remedy is metallic packing. ROBERT E. HICKS.

Houston, Tex.

Discussion on Ammonia-Compressor Diagrams

Regarding the ammonia-compressor diagrams of J. C. Harrison in the Jan. 15 issue, neither set seems to have been taken under correct conditions of suction-gas temperature. The Wolf-Linde compressor is of the wet gas type, in which the frost is carried right up to the compressor, the temperature being regulated by the amount of liquid ammonia carried into the cylinder with the suction gas.

With the temperature of the suction gas shown by diagrams Figs. 1 and 2, the temperature of the cylinder and discharge would be too high, and the ammonia rod would be hot and troublesome. With conditions as revealed by diagrams, Figs. 3 and 4, too much liquid ammonia is being carried with the suction gas, the temperature of suction gas being approximately 4 deg. F. below the boiling point of the ammonia due to a pressure of 24 lb. Better results are obtained when the temperature of the suction gas is about 10 deg. higher than the boiling point of the ammonia due to the suction pressure.

Fig. 1 indicates either incorrect gage readings or a mistake in locating the atmospheric line, as scaling with a 120-lb. scale shows the suction pressure 24 lb. and the head pressure 140 lb. Fig. 2 shows a larger reëxpansion loss than necessary with this type of compressor and may be due to excessive clearance. Figs. 3 and 4 show the loss in capacity due to too much liquid ammonia entering the cylinder. This is indicated by reëxpansion taking place during 30 per cent. of the suction stroke, being about 25 per cent. more than necessary with a correct suction-gas temperature.

I believe that in this case the compressor cylinder itself was well frosted, as the compression line leans more toward the isothermal curve than in Figs. 1 and 2, indicating that some of the heat of compression was being removed by the extremely cold cylinder walls.

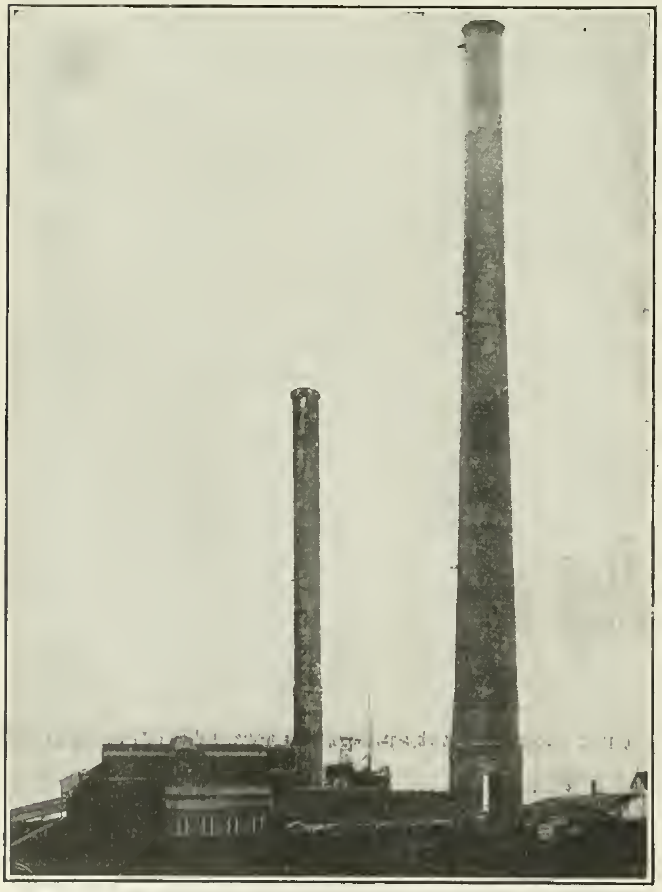
The discharge-valve springs on both ends of the compressor seem to be too strong, although this may be necessary owing to the speed of the compressor, as the normal speed for which this type of compressor was designed is about 50 r.p.m.

I would advise that lighter springs be tried and some diagrams taken with the suction temperature regulated to give a discharge temperature of 120 to 140 deg. F.

New York City. F. G. **Schoenfeld.**

Tallest Chimney in the World

In the issue of Jan. 8, 1918, page 56, it is stated that a smelter stack in Japan is 570 ft. tall and that it is claimed to be the highest in the world. I am sending a photograph of one recently completed in Tacoma, Wash., by the Tacoma Smelting Co., the height of which, from top of the concrete base, is 572 ft. 10 in. It is 50 ft. in diameter over-all at the bottom, where the walls are 4½ ft. thick. It tapers to 25 ft. outside diameter at top, with walls 17 in. thick. The chimney is lined and has a 2-in. dead-air space between the lining and walls. The concrete base is 31 ft. thick, and 2,400,000 bricks were used in constructing the chimney. The original contract called for 571 ft., but it was built 1 ft. 10 in. higher. I wish you would publish this in *Power* as we don't want anyone to get away with anything on us. Glenn Martin.

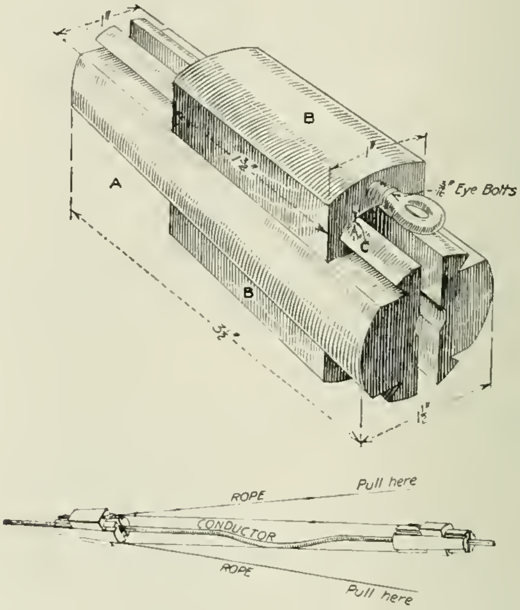


TACOMA, WASH., SMELTER STACK 572 FT. 10 IN. HIGH

Tacoma, Wash.

Wire-Tightening Tool

It is generally a somewhat difficult job, without the use of proper tools, to get a hold on an insulated or a bare wire to take a strain on it without injuring the insulation or kinking the wire, especially if the conductors are of large size. It was to provide a satisfactory means for putting the proper tension in electrical conductors when they are being run in the open on insulators that the tool shown at *A* in the figure was devised.



PARTS AND ASSEMBLY OF WIRE-TIGHTENING TOOL

The construction of the device is self-explanatory, and the dimensions given are sufficient for anyone to go ahead and make one. The one shown was made from a taper pin 1.5 in. in diameter on the large end and 1 in. on the small end. Eye-bolts in the pieces *B* are used to apply the strain to the conductor. The grooves in the movable parts must be cut of sufficient size to allow the large end of the V on the stationary parts to fit into them as at *C*, or the former will jam on the latter. To take a strain on a wire from two directions two of the tools may be used, spaced at convenient distances apart on the conductor, with a rope run through the eye-bolts to apply the tension, as shown at the bottom of the figure. The dimensions shown in the figure are right for a tool to be used on conductors up to ⅜ in. diameter.

The buying of War-Saving Stamps has developed a finer sense of thrift and economy among the people.

Inquiries of General Interest

Greater Sensitiveness of Loaded Governors—How does loading an engine governor affect its sensitiveness? W. N. B.

Omitting friction, the sensitiveness of a loaded or unloaded governor would be theoretically the same. But in practice the friction of a governor and its gear may be considerable, and the sensitiveness of a loaded governor is actually much greater than the unloaded one, as the friction is a smaller proportion of the total forces acting on the governor when loaded than when unloaded.

Long Pump-Suction Pipes Objectionable—What are the objections to a long pump-suction pipe? R. H.

Long suction pipes are objectionable because the greater amount of pipe friction to be overcome by the suction pressure requires the pump to make a higher vacuum; the momentum of the suction water at each reversal of the pump, or sudden stoppage of the pump, may be productive of damaging water-hammer; and in addition to having more joints to give trouble from air leakage, with the water taking longer time for its passage through the suction pipe, more air is liberated out of the water, thus impairing the capacity and proper operation of the pump to a greater extent than with a short suction pipe.

Location for Tightener-Idler Pulley—Where should a tightener-idler pulley be placed for increasing the driving capacity of a belt when there is short distance between centers of the main pulleys? H. B. F.

An idler should be employed for increasing the arc of contact of the belt on the smaller pulley rather than for increasing the tension of the belt and should be on the slack side of the belt near the smaller pulley. To minimize friction, the diameter of the idler should be as large as compatible with obtaining the necessary arc of belt contact on the smaller of the main pulleys, and the idler frame should be held to its position by means of screws or other adjustable fastenings.

Disadvantage of Excess Air—What is the disadvantage of excess air to a boiler furnace? R. A. E.

The surplus air has to be heated up to the furnace temperature without adding anything to the combustion, and carries off to the chimney as many units of heat as are required to raise it from the temperature at which it enters the furnace to the temperature at which it enters the uptake, or about 0.24 of one B.t.u. per degree difference of temperature for each pound of excess air. To be sure that each atom of carbon of the fuel will meet with an abundance of oxygen, it is necessary to admit 50 to 100 per cent. more air than is required for theoretically complete combustion, and determining what proportion of excess air is most advantageous is best done by flue-gas analysis.

Deposit of Scale at Girth Seam Over Fire—Where scale is formed by the feed water of a return-tubular boiler why is there greater accumulation of scale at the girth seam over the fire? J. J. O.

Local deposits of scale are generally due to the circulation. In a return-tubular boiler the heat of the fire causes disengagement of steam bubbles that, in rising to the steam space, induce an upward current of the water, which is replaced by a flow along the bottom from the rear of the boiler. The change in the direction of the circulation and also the obstruction offered to flow by the rivets and lap of the joint cause eddies and swirls that include places where the water is quieter and out of which a larger proportion of the suspended matter is precipitated than from water that is moving at higher velocity.

Wasting Live Steam When Used With Exhaust—In a plant where exhaust steam for heating is supplemented by live steam passed through a pressure-reducing valve, less total steam appears to be required from the boilers to do the same heating when no exhaust is used and the heating apparatus is supplied with only live steam. What is the explanation? A. B. C.

The results obtained signify that when the exhaust is used in conjunction with live steam, there must be a waste of more heat than the exhaust is capable of supplying. This may result from escape of steam through the back-pressure relief valve because the heating apparatus is oversupplied, or rejects steam at the relief pressure of the back-pressure valve; or from passage of unused steam through the apparatus and discharging it direct to the atmosphere; or that the excess of steam is received by a vacuum pump that removes more steam than should be necessary for obtaining good circulation in the heating apparatus. When live steam is used to supplement exhaust, a waste is likely to occur unless the discharge pressure of the live-steam pressure-reducing valve is well below the pressure at which the back-pressure relief valve opens, or when unused steam is allowed to escape from the heating apparatus.

Estimate of Chimney Draft—What should be the force of draft, in inches of water, of a brick chimney 120 ft. high with the temperature of the atmosphere 40 deg. F. and temperature of the chimney gases 500 deg. F.? N. G. D.

The force of draft may be found by the following formula, which makes an allowance of 20 per cent. for friction in the chimney:

$$D = 0.42H \times P\left(\frac{1}{t} - \frac{1}{T}\right), \text{ where}$$

D = Force of draft in inches of water shown by the difference of level of water in a U-tube;

H = Height of the chimney in feet;

P = Pressure of atmosphere in pounds per square inch (14.7 at sea level);

t = Absolute temperature of atmosphere (deg. F. + 460);

T = Absolute temperature of gases in the chimney deg. F. + 460);

Substituting gives,

$$D = 0.42 \times 120 \times 14.7\left(\frac{1}{500} - \frac{1}{960}\right) = 0.71 \textit{ in. of water}$$

Slippage and Readjustment of Eccentric—Without indicating an engine or uncovering the valve, how may it be known whether the eccentric of an engine has slipped on the shaft? H. G.

Slippage usually has the appearance of having occurred backward, though in fact due to the shaft having continued in forward rotation while the setscrew or other fastening of the eccentric to the shaft was not sufficient to overcome the resistance that the valve and valve gear offered to their motion. If the initial position of the eccentric cannot be determined by the setscrew impression on the shaft or other marking, then, to test the position, place the engine nearly on the center and turn it forward until steam begins to be admitted as may be seen by opening the throttle a little and observing when steam is seen to issue from an indicator hole or drip-cock in the end of the cylinder. Then place the engine on the other center to see whether the same amount of lead is obtained. If there does not seem to be the same amount of lead, readjust the eccentric forward or backward to compensate for one-half the apparent difference. It does not follow, however, that because the eccentric is turned to the correct position to give equal leads that the valve is properly set, for if the valve rod was not in proper length of adjustment, the other valve events will not be equalized.

Internal-Combustion-Engine Lubrication[*]

BY W. F. OSBORNE

Some of the important facts relating to the lubrication of internal-combustion engines are set forth and discussed.

THE film of oil placed on the cylinder walls by the piston on the compression strokes of an internal-combustion engine lubricates the piston on the explosion stroke. As the piston moves towards the crank, the walls are exposed to the high temperatures of the burning gases; thus the flame comes in contact with the oil film only after it has served its purpose of lubricating the piston on the instroke. The greater part of the damage to the oil film is done during the firing stroke. The oil between the rings and between the piston and cylinder walls also is subjected to the pressure of the burning fuel and thus assists the piston ring in preventing loss of power through leakage of gases into the crank case. If there is any trouble with the lubrication, it will occur on the exhaust stroke, as the oil film on the cylinder wall has just been exposed to the high temperature of the burning gases and has undoubtedly been somewhat damaged. However, if the oil possesses the proper characteristics, some lubricating value remains, which, together with the oil film on the piston itself, lubricates the piston on this stroke.

There are, in the mechanical construction and in the operating conditions of an engine, a number of factors which determine the characteristics of an oil that will satisfactorily meet the requirements cited. Some of the more important of these are: Temperatures in the cylinders, piston clearance, speed, cooling systems, ignition, fuels, carburetion and oiling systems.

EFFECT OF TEMPERATURE CONDITIONS

The temperatures existing in the cylinder of a four-stroke-cycle engine as given by Lieut. G. S. Bryan, U. S. N., in his paper on "Motor Cylinder Lubrication," published in the Journal of the Society of Naval Engineers, February, 1915, are as follows:

Maximum temperatures obtained at top of explosion stroke, 2700 deg. F.; minimum temperature during suction stroke, 250 deg. F.; and an average temperature during the complete cycle, 950 deg. F. These are the temperatures of the gases in the cylinder, and not of the cylinder walls.

Basing calculations on an investigation made by the Bureau of Mines in 1912, of the transmission of heat in steam boilers, it would appear that the temperature of the inner surface of the cylinder walls ranges from 55 to 60 deg. higher than that of the circulating water. Later investigations have shown the temperature difference to be as low as 30 deg. in some instances. As long as the water is not boiling, the cylinder-wall temperatures will hardly be much better than 267 deg. F., while at normal circulating-water temperatures of 140 to 150 deg. F., the wall temperatures will probably range from 170 to 210 deg. F. The temperature of the center of the piston head, which in most cases is not water-cooled, runs from 800 to 1300 deg. F.

The maximum temperature of 2700 deg. F. occurs when the piston is practically at dead-center, and the temperature then rapidly drops as the piston moves inward, uncovering the oil film and exposing it to the flame until the end of the stroke. The outer surface of the oil film in contact with the cylinder walls at the comparatively low temperature of between 170 and 210 deg. F. is probably never affected by the high temperatures, but the inner surface of the oil film, directly exposed to the flame, is undoubtedly damaged, probably the greater part being destroyed.

With a maximum gas temperature of 2700 deg. F., and an average temperature of 950 deg. F., as it is impossible to produce a petroleum lubricating oil of any kind having a flash point over 700 deg. F., it would seem that any oil film would be promptly destroyed and that the so-called high-flash oil of 450 deg. F. would afford very little more resistance to burning than a low-flash oil of 325 deg., under these conditions. Either oil will burn if kept in contact with these temperatures for any appreciable time, so that the outer surface of the oil film will be affected, regardless of the flash point of the oil. However, lubricating oils burn comparatively slowly, and in the short period the film is exposed to the flame it will not be completely destroyed if it is of the proper thickness. It would therefore appear that the film must be thick enough to permit of a part being destroyed and at the same time sufficient thickness of good oil being maintained to lubricate the piston and cylinder on the exhaust stroke.

While the high temperatures of the exhaust gases, around 800 deg. F., continue to destroy the film on the exhaust stroke, the advancing piston smears a fresh film of oil over the cylinder's surface, which lubricates the piston for the suction stroke. The cool, fresh charge of fuel, even when mixed with the exhaust gases remaining in the cylinder, does not average over 250 deg. F., so that no damage is done to the oil from high temperatures on this stroke. As the increase in temperature on the compression stroke does not become very great until the piston has completed the greater part of its stroke, there is very little effect on the oil film. An oil to be suitable should maintain a film of a proper thickness under the working temperatures of the cylinder.

THE EFFECT OF PISTON CLEARANCE

The seal between the pistons and cylinders obtained by mechanical means is secured at the expense of greatly increased friction. In fact, the rings can be so tight that the engine cannot be turned over at all. A more desirable form of seal can be secured by making use of the film of lubricating oil necessarily existing for lubrication. As the piston advances, a supply of oil builds up on the edge of the piston head and on the advancing side of the rings, which opposes the force of the compressed gases, and if the lubricating oil has sufficient strength or viscosity to resist the force of the gases, a perfect seal is obtained.

The benefits secured by a perfect seal maintained by the lubricating oil are: Minimum lubricating-oil consumption; minimum fuel consumption, by preventing leakage of fuel past the rings on compression and waste of power on firing stroke; minimum friction, through the use of looser-fitting pistons and rings working on a lubricating film; minimum carbon, due to minimum quantity of oil working into the combustion space. Where a crank-case oiling system is provided, a perfect seal, by preventing the hot gases from reaching the crank case, maintains lower oil temperatures and thus prevents excessive bearing and cooling-water temperatures. In the operation of crank-case oiled engines, a perfect seal is of great benefit, as it prevents liquid fuel or vapors from passing the rings and later condensing into a liquid in the crank case, thus thinning down the oil and destroying it.

CAUSE OF THINNING DOWN OF OIL

Some elaborate experiments were made in 1911 to determine the cause of this thinning down of the oil. During these experiments many different kinds of oil were run to the breaking point in a Singer motor. An examination before and after the test showed, in every case, that the body of the oil had become lighter and that the flash point had been lowered, sometimes to the surprisingly low point of 150 deg. F., whereas the original oil had a flash point of 450 deg. F. To determine whether this was caused from the breaking down of the oil or its being thinned by the amount of fuel working past the piston rings, tests were made, using benzol as a fuel. The presence of benzol is readily detected in lubricating oil, whereas gasoline or kerosene and the products of the decomposition of a petroleum oil, which are similar to gasoline, are not. These

---

[*] Abstract from a paper published in January, 1918, issue of the National Gas Engine Association's Bulletin.

tests established the fact that the gas leaked past the piston rings, evidently afterward condensing and affecting the motor oil. As high as 3 per cent. of benzol was found in the motor oil after four hours' running. The effect of this admixture of fuel is to lower the flash and fire, increase the Baumé gravity and lower the viscosity. Many tests made in subsequent years confirm these general facts.

Judging from these tests it would appear that a large proportion of motors of this type operate on an oil that is quite different from the new oil introduced into the engine. This varying condition of the oil is directly the result of the condition of the engine, and the condition of the engine, as time goes on, is the result of the changed condition of the lubricating oil. What becomes of the argument that a high-flash oil is necessary to properly lubricate motors, when this same oil promptly has a flash point of 200 deg. F. when the motor is warmed up and operating?

THE EFFECT OF TIME OF COMPLETE CYCLE

A thin film of oil smeared on a hot (300 deg. F.) piece of iron or steel will burn several seconds if ignited, so that even with the engine running as slowly as 100 r.p.m., if the oil film is of reasonable thickness it will not be entirely destroyed. When the speed is increased to 1000 r.p.m., as in the case of automobiles, which allows a total time of 0.06 of a second, and even less with higher speed motors, for the lubricating-oil film to be exposed to the burning gases, the viscosity of the oil, and consequently the thickness of the film, can be reduced considerably without meeting with trouble. In any case the viscosity should be high enough to maintain a film of such thickness that it will not be destroyed on the firing and exhaust strokes.

Air-cooled motors, such as motor-cycle engines, air-plane engines and one or two types of automobile engines, naturally run with very hot cylinders. With circulating-water systems it is possible to hold the cylinder-wall temperatures at a much lower point, and the required viscosity of a suitable oil will be higher or lower as the cooling water leaving the cylinder jacket is hotter or cooler. With a given oil the cooler the engine the better will be the seal, owing to the increased viscosity of the oil.

If ignition takes place at exactly the proper time, resulting in the most complete combustion possible of the fuel mixture supplied, the temperature falls off rapidly. If the spark is retarded, a slower and later burning results, extending over a considerable portion of the stroke. Continuous retarded-spark operation raises the temperature of the cylinder walls and the cooling water, thinning down the oil and frequently reducing its viscosity to the dangerous point.

EFFECT OF DIFFERENT FUELS

Natural gas, blast-furnace gas, producer gas and coke-oven gas, being comparatively slow-burning, do not produce high initial temperatures, but expose the oil to more severe temperature conditions. These slow-burning gases are generally used in comparatively low-speed engines on account of the time required for complete combustion, and a thicker oil film on the walls is necessary for protection against the long exposure to high temperatures.

Kerosene being slow burning, slower than gasoline, permits of higher compression, and requiring somewhat higher circulating-water temperatures, imposes a severe service on the lubricating oil, which must have exceptionally good body and lubricating qualities to stand up to the requirements.

The question of complete carburetion or vaporization of the fuel has great bearing on the efficiency of lubrication. The ideal condition is, of course, high initial pressure, and very early, complete combustion, approaching the gunpowder explosion. In this case the maximum temperatures are obtained when the piston completely covers the working surface of the cylinders and the lubricating film is not exposed to these extremely high temperatures. If the fuel is not completely vaporized and thoroughly mixed with the proper proportion of air, slow burning occurs, with the bad effects indicated in the foregoing.

The method of supplying the oil to the cylinders and bearings affects somewhat the viscosity of the oil that can be used, in that the suitable oil must be thin enough to flow to the parts to be lubricated from the point of supply; but instead of selecting an oil that is suitable for working in the system provided, it seems much better to select an oil suitable for the parts to be lubricated and then arrange the oiling system to properly handle that oil.

The most discussed, perhaps because it is the most visible, effect of unsuitable oil, is the carbon deposit in the combustion space, on the valves, the piston head and behind the rings. It is generally assumed that all carbon deposits are caused by poor oil or by poor gasoline, whereas the carbon deposits may be caused, and probably in many cases are caused, by the use of unsuitable oil or imperfect carburetion. An analysis of the carbon deposits in a cylinder generally shows the presence of considerable quantities of dust, drawn in through the air intake, and rust held together by a small quantity of oil.

A motor oil should consist of refined and filtered mineral oils or mixtures, having a cold test of not over 25 deg. F., fully suitable for use in internal-combustion engines. An oil meeting these specifications would be perfectly satisfactory when used in an engine for which it was suitable, its suitability being largely determined by its viscosity.

There are a number of tests that are used for the purpose of determining the suitability of a lubricating oil, which it might be well to mention, together with the qualities they determine.

The gravity reading is merely an indication of the crude from which a lubricant is refined, and is no indication of its lubricating value for internal-combustion cylinders.

Flash and fire tests are no indication of the ability of an oil to stand up under the working temperatures of the cylinders. As previously stated, the temperatures in the cylinders are far beyond the highest possible flash tests of any lubricating oil, and a high-flash oil would afford very little more resistance to destruction than a low-flash-test oil.

The pour test is an indication of the temperature at which the oil will flow, and where the engine is operated under conditions of temperature below 30 deg. F. the pour test of the oil is of considerable importance.

VISCOSITY OF OILS

The viscosity reading is the measure of the body of the oil, and may also be considered as a measure of the thickness of the film of oil maintained on the cylinder walls. It is also an indication of the ability of the oil to resist the pressure of the explosion gases, which tend to force their way past the piston rings. In other words, the higher the viscosity the greater will be the ability of the oil to withstand the high temperatures encountered and the better would be the effect in maintaining the piston seal.

The average purchaser of motor oils, having no data on their actual viscosity readings, must select the oil according to the general trade name of light, medium, heavy and extra-heavy motor oils. These terms at present having a somewhat indefinite meaning, it would appear that there is a great need for the standardization of viscosity, and the following suggestions are made, based on the viscosity of 100 deg. F., Saybolt Universal Viscosimeter: Motor oil, light, from 170 to 230 sec.; medium, from 270 to 330 sec.; heavy, from 470 to 530 sec.; extra-heavy, from 720 to 780 seconds.

Color in itself is no indication of the lubricating value of an oil. About the only information as to its value that can be obtained from noting the color is whether or not the oil is contaminated by moisture or foreign matter.

The author realizes that there are a number of additional influences affecting the selection of suitable oils, but it is hoped that the points brought out will be of some benefit to those interested in the use and purchase of internal-combustion cylinder oils.

Under the Iowa statute which empowers cities to fix the rates to be charged by electric-power companies and other public utilities, and under a power company's franchise, fixing a schedule of charges on the basis of kilowatt consumption, without any provision for meter charges, the company is not entitled to increase its service charges by imposing a meter fee or by any other subterfuge. (Iowa Supreme Court, Iowa Railway and Light Co. vs. Jones Auto Co., 164 Northwestern Reporter, 780.)

Mixing Coal in Storage*

BY GEORGE FREDERICK ZIMMER

Because of the problem of mixing culm and other fine coals with bituminous coal preparatory to use in boilers, the following article should be of especial interest to American engineers.

THE writer will here deal with the subject of accumulating coal in such a way that it can be reclaimed from the base of the pile. This method is more scientific and has the advantage that not only is accumulation of the small coal prevented, but the coal at the deepest part of the pile is kept just sufficiently in motion for the bulk to be slightly broken every time coal is withdrawn, two advantages that minimize spontaneous combustion and therefore make a deeper or higher pile admissible with a sufficient degree of safety. This is important if the available storage area is limited, as is often the case in plants within the precincts of large cities.

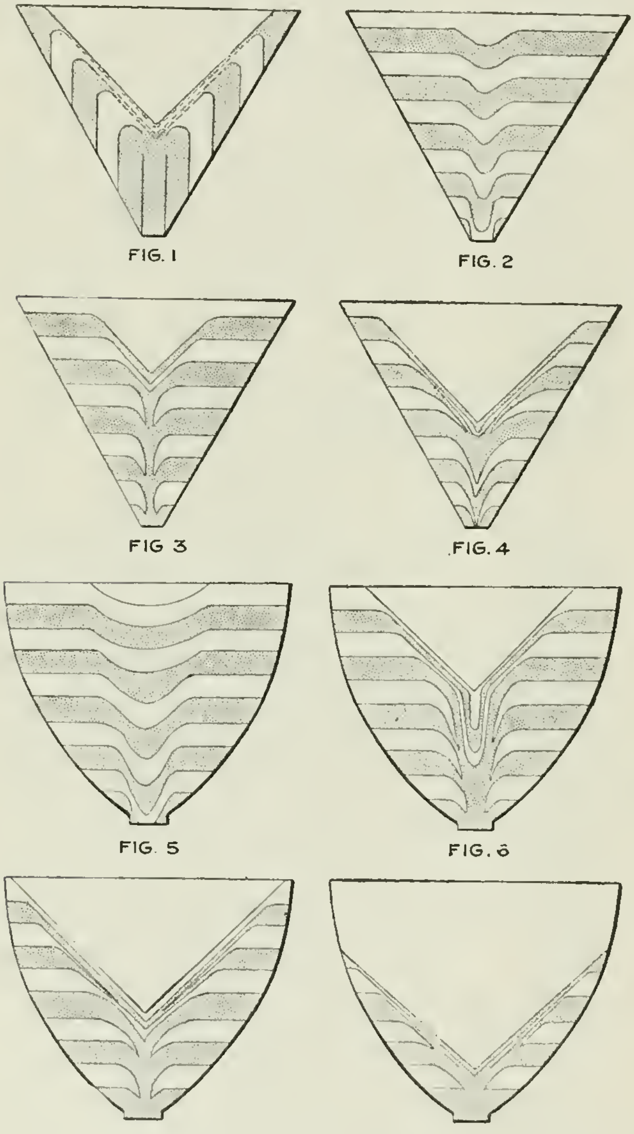

FIG. 1 FIG. 2 FIG 3 FIG. 4 FIG. 5 FIG. 6 FIG. 7 FIG. 8

FIGS. 1 TO 8. SHOWING MOVEMENT OF COAL AS IT RUNS OUT OF VARIOUS SHAPED BUNKERS AS REVEALED BY COLORED MATERIAL DEPOSITED IN ALTERNATE LAYERS

Concerning the movement of the coal in a hopper pocket, it might not here be out of place to record the results of some tests made by the writer. The diagram, Fig. 1, shows the movement of a granular material, which was deposited in alternate vertical layers of different color, during withdrawal; while Figs. 2 to 4 show three stages of a similar test where the material was arranged in alternate horizontal layers. The movement in bunkers of the form now frequently employed is shown in Figs. 5 to 8.

As the diameter of the descending column in the bunker depends upon the size of the outlet, it is well to make this as large as possible and withdraw the coal relatively slowly by employing mechanical feeding devices. A large outlet is advantageous for a twofold object; namely, the slowly descending column of coal will have a ventilating or cooling effect if there should be a tendency to heat, and a larger outlet will prevent, or at least lessen, the tendency for large pieces to bridge or cave and cause a stoppage in the coal supply through the outlet.

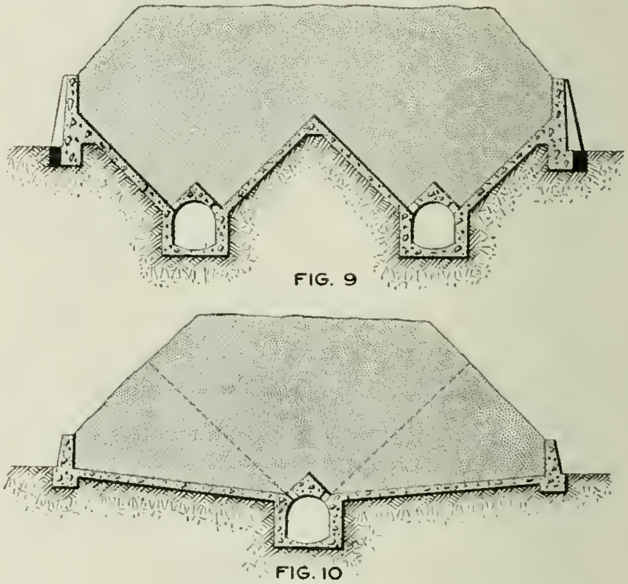

FIG. 9 FIG. 10

FIGS. 9 AND 10. CONCRETE BUNKERS WHICH DROP COAL INTO CARS LOCATED IN TUNNELS BENEATH THE PILE

The diagrams give a clear picture of what takes place, and if the sides of the hoppers are chosen of a more shallow or even a somewhat more acute angle, it will not alter the proceedings; as soon as a funnel-shaped depression has been formed of the angle of repose of the coal, the pieces around the crater will roll down and descend.

The experiments were made with a model having a glass front, but in practice the same process can be proved to take place, for if the upper layer of coal is limewashed, this washed surface will not be disturbed beyond the formation of a crater; that is, the central column will be withdrawn from the bunkers before the whitewashed pieces begin to descend, and they will presently appear through the outlet. This shows, incidentally, that the coal deposited last in the bunker will mix with some of that stowed earlier, so that we might almost depend on having in the descent an average sample of the contents of the bunker, provided the outlet is big enough. Where gas pipes are used in such coal stores for the reception of thermometers—to record any change in the temperature—these pipes remain in an upright position as the coal-level in the bunker becomes lower, until practically two-thirds of the coal which used to hold them has been withdrawn.

---

*From an article in the Jan. 18, 1918, issue of "Engineering" (London), entitled Modern Methods for the Storage of Coal.

Coöperation an Essential Element in the Winning of the War

By E. W. Rice, Jr.
President, General Electric Co. and the A. I. E. E.

Abstract from a lecture delivered Feb. 15, at the dinner of the sixth annual midwinter convention of the American Institute of Electrical Engineers held in New York City. The speaker outlines what the country has already accomplished since entering the war and then points out the great need of coöperation between the industrial organizations of the country, and between these organizations and the Government in order that the maximum output of brains, labor and material may be obtained.

There was never a time in the history of the world when work was more needed and when talking is only justified which may help forward the great work at hand. We all know what that great job is—the winning of the war. Everything else must wait and take a back seat until that job is done.

We were all greatly encouraged and thrilled during the early months of the war by the patriotic attitude of Congress, which supported the Administration in an unprecedented manner, without distinction of party.

Activities This Country Has Started

The two great Liberty Loans, aggregating between five and six billion dollars, were voted and raised with the patriotic and enthusiastic support of all the country, and we are told that when history has been written wicked Wall Street will deserve a decoration for its patriotic and efficient assistance. A great scheme of taxation, more drastic and bearing more heavily upon the wealth of the country than anything known in our history, has been passed and will be loyally supported even by those who are most heavily hit.

The selective-draft system was prepared and put into operation and accepted by the country in a truly magnificent manner. The Red Cross has been reorganized and an enormous amount raised by voluntary subscriptions and is well started on its beneficent and valuable mission. The Knights of Columbus are also doing magnificent work in a similar field. I will not take your time to sketch any further the tremendous activities which this country has started during the past year.

In view of this record of accomplishment and our truly splendid start in the war, why has this feeling of nervousness come over the country? Why has Congress suddenly changed its attitude of unquestioning support to one of investigation and criticism? What does it all mean? Is it true that we are making a failure of the job?

It seems clear to me that we have not made a failure and that everything is moving along as well as we had a right to expect under all the circumstances. When we consider that less than a year ago, our nation of a hundred million of people, entirely unprepared for war, with institutions and traditions adapted only to the conditions of profound peace, was thrust into this greatest of enterprises, I think we have already accomplished wonders and that we should not be discouraged. In spite of eminent authority a million men cannot spring to arms over night, nor can dreadnaughts, destroyers, submarines, anti-submarine devices, heavy ordnance and all the great mechanism of war be produced in a day, in a month, or even in a year, no matter how much we pray or "cuss" or work. Business men, and especially engineers and manufacturers who understand the nature of the equipment required for this conflict, however, must appreciate that our fundamental, and let us hope not fatal mistake, is that we waited until the war was thrust upon us before we started to get ready.

I think that a little reflection will make it clear that the mistakes we have made since we started in the war, however numerous or avoidable, are in the aggregate negligible compared with the overwhelming mistake of failure to prepare for the war during 1915 and 1916. That precious time has been lost forever, and no effort or time, criticism or talk can cancel that mistake and give us back the lost time. We must expend untold billions and we must make superhuman efforts, but we must also be patient and realize that inconsiderate haste is likely to result in added friction, lost motion, false starts and a general retardation of our program.

Done Well Since We Started in the War

While it would seem that, considering our history and our type of government, with its checks and balances, we have done fairly well since we started in the war, we realize that we have fallen short of what we would like to have accomplished, and we should not be satisfied nor should constructive criticism be discouraged. I believe, however, that we should not become unduly disturbed, but rather be encouraged at the prospect. "While there is life there is hope," and the very fact that the country has energy enough to kick violently while it is working, clearly demonstrates that there is no possibility of dissolution or thought of defeat.

It seems quite probable that the questioning attitude of the country today is due more than anything else to a growing fear that the full ability, wisdom and experience of the country is not being properly utilized. When at war every important force in our nation must be enlisted to the fullest extent and in the most efficient manner. The support of the country has been magnificent. Would not this confidence be greatly strengthened if those in political control would look beyond their party and take into the service of the nation its strongest men without reference to political affiliation?

There are plenty of such men who are willing to help the country, and the country wants them put to work worthy of their records and abilities, not under dictation but as partners of our great enterprise. England has met the situation by a so-called Coalition Government. Why can't we do something similar?

Large Number Volunteer for Service

The country is greatly encouraged at the large number of able men, prominent in business and other walks of life, who have volunteered for service in various departments of the Government and who have been accepted and set to work. This policy should be encouraged, as the more it is followed the better the country will be satisfied and the sooner we will win the war.

It is essential that the men who are charged with enormous responsibilities in our Governmental enterprises have the confidence of the country, as their orders, no matter how drastic or arbitrary or apparently unnecessary, should be followed with confidence. At the present time orders are patriotically obeyed, but with some misgiving. There is no lack of confidence in their good intentions and character, but there is some questioning of their wisdom and practical experience.

Every organization must demonstrate what it can do to help the country in its hour of need. Every organization, whether of capital, labor, manufacture or business, and every individual must be subjected to the test of whether it is doing its best and most effective work to win the war. This will be the only and supreme test. Every individual who fails to put forth the maximum effort in the most efficient manner must be brought into line.

It is obvious that no single element by itself can win the war. Capital alone is helpless; labor alone is equally helpless. The Navy cannot win without the help of the Army, and both are helpless without ships. The sacrifices cannot be made by capital alone, or by labor alone, but must be distributed on a fair basis.

The test of patriotism will be the willingness to work, each in his own sphere, to the absolute limit. We need the maximum output of brains, labor and material; the country demands it, and the country will see that it is obtained. Any man or organization of men that stands in the way of the purpose which this country has set for itself will be eventually crushed.

It is manifestly impossible to build up a new organization that will operate satisfactorily at once. It has taken many years to build and perfect the great industrial organizations of our country. The transfer of a man to Government service does not change his character or necessarily increase his efficiency. After any organization has been brought into existence, time is required for the different units to learn their duties and particularly to learn how to coöperate with one another.

It takes time for us to get over our ideas and practices, based upon our competitive conditions and education. We are now to forget our education in competition, and think of nothing but coöperation; in other words, of what is best to increase the country's production as a whole, for that is vital in winning the war.

It is obvious that the Navy and Army cannot be built up without drawing upon the organization and facilities of the country and that their activities cannot be maintained without an efficient industrial organization constantly at work behind them in this country. Therefore, our Government, as well as ourselves, must never forget that the preservation of the country's industries in the highest state of efficiency is a vital matter.

I like the President's expression, "Spirit of accommodation," for that is an essential element of coöperation.

Now I wish to emphasize the fact that it takes time to produce really efficient coöperation. No new organization can possibly work as smoothly and effectively as one which has had time to become perfected. Moreover, coöperation in Washington between departments will not entirely settle the matter. We have a duty to perform. There must be coöperation among the industries. We must forget to compete and learn to coöperate with other units.

But this is not all; we must have coöperation between the Government and industries, and to be effective, this means that each must be a party to the coöperation. It cannot be a "lion and lamb" sort of affair. If the Governmental heads use their vast power arbitrarily and unwisely, they can easily cripple the industries of the country, and thus delay victory for years.

I believe that the problems facing us will be successfully solved in time, but we need more coöperation, more of the spirit of accommodation, all our patience and wisdom and, above all, a willingness to work to the limit.

We must discipline ourselves until a shirker in any field of useful effort will be regarded with the same contempt as a shirker in the military service of the country, for there is no difference, or if there is any difference, a shirker behind the lines is worse than one in the trenches.

It has taken a world tragedy, the tragedy of war, to arouse the nation to an appreciation of the value of its technical men. This great strife is not, as in other ages, a contest of brute force in which the bulkiest muscle is bound to win, but it is a battle of intellectual giants struggling for supremacy in destructive creation, and protective and defensive development. The civil engineer, the mechanical engineer, the electrical engineer, the mining engineer, the chemical engineer, the aëronautic engineer, the marine engineer—a great coöperative brotherhood working for peace and victory—have cast their skill, knowledge and effort into a crucible from which our country is drawing the metal from which victory will be fabricated and a world peace be secured.—*American Association of Engineers.*

Ships, Ships, and More Ships

The question of whether we are going to allow our country to become a German province has now to be answered. And it must be answered by ships, and ships, and more ships. It must be answered now—at this moment. We have got to decide instantly whether we are going to live up to our promises to our Allies—to England and her colonies, that are putting their last men into their armies; to France, that is in desperate straits; to Italy, which has so bravely pulled herself together after an almost withering defeat.

Without ships we cannot win the war; we cannot justify the faith with which our Allies honor us. Wanting ships, we can send no more men to the battlefield; we cannot even maintain the American soldiers who have reached the other side and who depend for their very lives on the support of their fellow-citizens at home.

To build ships we must have men. Our shipyards will need, must have, 250,000 workers. Men of all trades who can work in wood, iron or steel with a fair degree of skill will be welcomed by the Government and by the Shipping Board, so long as they are willing to serve with faith, loyalty and perseverance. Workmen in our shipyards to-day are absolutely vital to our military success, and those who answer the call will be just as truly defenders of our country and its Allies as are our soldiers on the fighting front.

The men required are not asked to give up their jobs and move somewhere else immediately. That would cause confusion. What is asked is that every man who stands ready to go to work building ships when the United States Shipping Board asks him to, shall now enroll in the United States Shipyard Volunteers of the Public Service Reserve. Such enrollment will include registration and an examination as to fitness for the work. Application for enrollment can be made at any office of the United States Employment Service, and such offices are now being established all over the country.

If there is no enrollment agent of the Public Service Reserve in your community, see the local representative of the State Council of Defense, or write to Edward N. Hurley, Chairman, U. S. Shipping Board, Washington, D. C.

Culm and Bituminous Coal as Fuel

In an address delivered before the manufacturers and business men of Reading, Penn., William P. Frey, fuel engineer of the Lehigh Coal and Navigation Co., gave some interesting figures relating to the use of a mixture of anthracite culm and bituminous coal as a fuel. The tests from which his figures were obtained were conducted at the plant of the Carpenter Steel Co., Reading, Penn., from Nov. 19 to Nov. 24, 1917. The following excerpts are taken from Mr. Frey's address:

Given the large amount of anthracite culm available for immediate use and the great shortage of bituminous coal, is there a possibility of combining the two fuels into one? What are the proportions to be used, and what will be the resulting effects practically and economically?

The first question is answered by mixing soft and hard coal mechanically or by hand and developing a firing practice to burn the combination of the two. In a small plant the mixing may be done very much like the mixing of sand, gravel and cement, using a box or wheelbarrow as a measure. The better the mixing the better will be the results. Accordingly, all lumps that will not pass through 1½-in. round mesh should be crushed to smaller sizes. In large plants this crushing can be done through a rotary crusher. The mechanical mixing can be done in many different ways—common dump pockets, screw conveyors, paddle mixers, rotary drums, spray-out mixing devices like revolving tables with scraper arms or shaking tables with collecting chutes and spouts.

If the mixing is done properly, firing practice need not be changed, though there should be a tendency to damp off fires. Firing in thin layers will give better results but not quite so high ratings. Grate bars up to ½-in. air space can be used, as the culm bakes with the soft coal to a coarsely granulated material having the appearance of coke, which will not fall into the ashpit.

In all these tests the mixing was done by hand. Beginning with bituminous coal only, culm was added in increasing amounts until the mixture consisted of 66.7 per cent. of bituminous coal and 33.3 per cent. of culm. The results obtained are given in Tables I and II.

TABLE I. RESULTS OBTAINED USING NATURAL DRAFT

Average feed-water temperature	198 deg. F.
Average steam pressure, gage . . .	112.5 lb
Average stack draft, water gage .	0.4 in.
Cost of bituminous coal per short ton, delivered .	$4.60
Cost of anthracite culm per short ton, delivered	$1.90

Bituminous Coal Per Cent.	Culm Per Cent.	Equiv. Evaporation from and at 212 Deg. F. per Pound of Dry Coal Pounds	Boiler Rating Per Cent.	Boiler Efficiency Per Cent.	Cost per Boiler-hp. Per Hour Cents
100.00		10.03	112	69	0.78
80.00	20.00	9.47	106	68	0.73
75.00	25.00	8.76	96	64	0.75
66.67	33.33	7.34	80	55	0.89

TABLE II. RESULTS OBTAINED USING FORCED DRAFT

Average feed-water temperature	198 deg. F.
Average steam pressure, gage	112 lb.
Average stack draft, water gage	0.15 in.
Cost of bituminous coal per short ton, delivered.	$4.60
Cost of anthracite culm per short ton, delivered	$1.90

Bituminous Coal Per Cent	Culm Per Cent.	Equiv. Evaporation from and at 212 Deg. F. per Pound of Dry Coal Pounds	Boiler Rating Per Cent.	Boiler Efficiency Per Cent.	Cost per Boiler-hp. Per Hour Cents
100	.	10.80	140	75	0.73
65	35	9.90	112	74	0.63
50	50	8.42	96	66	0.65

The boiler used was a Newburgh fire-tube boiler, having 1549 sq.ft. of heating surface and 32.25 sq.ft. of grate surface. Forced draft was supplied by two calibrated Parson blowers, the steam used by them being deducted to obtain the data in Table II.

Chemical analysis of the bituminous coal showed 2.41 per cent. of moisture, 9.66 per cent. of ash, and 17.34 per cent. of volatile matter. The heating value was 14,000 B.t.u. per pound of dry coal. Similar analysis of the culm showed 9.65 per cent. of moisture and 25.60 per cent. of ash. The culm was clean and its heating value was 10,800 B.t.u. per pound of dry coal.

The tests were run under ordinary normal conditions, without overworking the firemen, and all the test results are given in the tables. The Carpenter Steel Co. ran two check tests, and their results agreed very closely with those shown. The points to be observed are that with natural draft at least 20 per cent. of culm should be used, and if forced draft is employed, the amount of culm in the mixture should be increased to at least 35 per cent.

National War Savings Committee of New York

The method of procedure followed by divisional chairmen of the Commercial, Industrial and Professional groups of the National War Savings Committee of New York is about as follows:

The chairman, immediately upon his selection, proceeds to organize his division by appointing as follows—provided his group is of sufficient size to warrant a duplication of the state organization: vice-chairman, secretary, manager of publicity, manager of speakers' bureau, manager of war-savings societies, executive committee of 3 or 4, managing committee of 15 or 20. As soon as possible, the chairman sends to everyone in his division a letter urging all firms and corporations, co-partnerships or individuals doing business, to take out selling agencies. The letter should cover the following points:

1. The Government is anxious to make War-Savings Stamps and Thrift Stamps the easiest things in the world to buy, the object being twofold: First, to obtain funds to carry on the war and second, to encourage the habit of economy among the people.

2. No capital is required to become Treasury Department agents—merely the investment of a few dollars in stamps, which can be obtained from the postman or post office after receiving appointment as an agent, and that the stamps, which are sold at cost to employees, members of the firm or to the general public, may be replenished from time to time, depending on requirements.

3. After an application has been filled out in the name of an individual and returned to the chairman direct or to state headquarters for Greater New York, 51 Chambers St., New York, a full supply of posters, literature and information regarding sale of these stamps will be sent to the applicant.

4. It is the duty of all to apply for agencies to sell these stamps, even if, as in some cases, only a few dollars' worth of stamps will be sold.

5. Foremen and department managers should be induced to become selling agents, as a greater interest is usually maintained when the employee is the personal representative of the Treasury Department and not the employer.

A few days after a general letter has been sent out, the members of the committee generally make personal calls on all those in their divisions, urging them to carry out to the fullest extent of their ability the suggestions contained in the letter.

Quotas are assigned to the various trades, and in order that these may be made on a fair basis, divisional chairmen send in, as soon as their committees are completed, to the vice-chairman of the Pioneer Division, approximate statements as to the number of employees in their group.

When 100 per cent. of all the firms in a division have become selling agents, it is suggested that committeemen secure members for the United States Government War-Savings Limit Investment Society of New York. This field is limited, however, to employers and principals, so that no very strenuous campaign is necessary to secure membership.

The principal idea of the Limit Club is that every individual who can possibly afford to take the limit allowed by law ($1000 at maturity, which costs only $826 in February, 1918, $828 in March, etc.) do so.

All employers are urged to start their employees saving by the gift of a 25c. Thrift Stamp and card, or the gift of the sixteenth stamp in order to complete the Thrift Card, or—as in some cases it has been done—by the gift of both the first and last Thrift Stamp for their employees. Various schemes can be worked out which will stimulate the sale of stamps among employees.

Food Administration on Ammonia and Ice

In view of the discussion of the Food Administration's ruling and desires relative to ammonia and ice harvest, the following letter from the Administration is of interest:

Your [*Power's*] letter of Feb. 5 addressed to Mr. Hoover on the subject of the ice industry has been referred to this division for reply, as the matters therein mentioned come directly within our jurisdiction, and we take pleasure in giving you below the Food Administration's position on the subject.

It is our desire that every possible ton of natural ice be harvested and stored now, in order to displace a similar amount of artificial ice and thereby permit of the diversion of ammonia from the manufacture of artificial ice to the making of ammunition for our soldiers. There is serious danger of a shortage of ammonia, and ice producers are not only serving their country by heeding our request to store natural ice, but they are actually protecting their trade and insuring their customers against a serious misfortune, which might follow in the event that the War Department felt it necessary to commandeer a considerable amount of ammonia and thereby materially curtail the manufacture of artificial ice. We hope and expect that by the coöperation of all parties in interest, and by careful conservation of the limited supply, it will be possible to avert a depleted ice supply during this year, but this possibility must be kept constantly in mind.

In your letter you referred to a conversation with a member of the committee of New York ice men, which, some time ago, was in conference with officials of the Food Administration. We do not see how any member of this committee could take the position that "he does not know what Washington wants," for we thought our position was made very plain, and men representing 96 per cent. of the ice-producing capacity of New York City have signed agreements whereby an additional million tons of natural ice is being harvested in New York today. This will result in the saving of approximately two hundred thousand pounds of ammonia and will guarantee that New York City will not suffer an ice famine this summer and that the people will not have to pay exorbitant prices for ice.

As you know, nearly all ice factories have large storage rooms, which they fill by operating at capacity during the winter months, in order to have ice in the summer to take care of their peak load. In general, it is not desired to stop the filling of these rooms. However, it is desired that wherever possible, they be filled with natural ice instead of the artificial article, in order to save as much ammonia as possible.

It is also the case that in most communities there are more ice factories than are necessary to supply the trade, and there is a consequent waste of ammonia and fuel, duplication of delivery service and a general economic waste. We are asking that wherever possible, this condition be cured by having the individual firms enter into a voluntary agreement with the Food Administrator, whereby a few of these plants may operate at capacity and the others be shut down, the plants which are closed to be furnished with ice for their customers by those in operation at practically the cost of manufacture.

We are restricting the supply of ammonia for ice-producing plants and refrigerating plants to their legitimate 60-day requirements, in order to insure against the hoarding of this chemical, and are only allowing the sale of ammonia for new plants when we can be convinced of their urgent necessity in the community where it is proposed to erect them.

With regard to your suggestion that it may be unwise to fill up cars with ice and thus add to the congestion of the railroads, we beg to advise that most of this ice is stored very close to the point where it is harvested and that it will add very little to the difficulties of the transportation situation. It can be hauled the short distance necessary in old cars which are not suitable for through traffic, and will not, in any event, seriously affect the transportation system. We might add that a general embargo-lifting order was issued on Feb. 11 by the Car Service Commission, covering about 75 or 80 different seasonal commodities, which would indicate that the railroad situation is improving in a very marked degree, and that no one need worry greatly about the effect of the natural-ice harvest on railroad congestion.

We trust that this gives you sufficient information, but if there is any point that we have not covered or on which you desire further advice, we shall be glad to have you call on us. The Food Administration appreciates your attitude and desire to be of assistance to us in this matter.

U. S. Food Administration,
Charles W. Merrill, Division of Chemicals.

Annual Exhibit of Evening Work at Pratt Institute

Thursday evening, Mar. 7, will be "Visitors' Night" at the School of Science and Technology of Pratt Institute, Brooklyn. From 8 to 9 o'clock all the shops, laboratories and drawing rooms of the school will be open to the public, giving an opportunity to those interested in industrial education to observe the students at work in the various courses and to inspect the results and methods as well as the equipment and general facilities of the institute for conducting this kind of industrial training.

The school provides instruction in industrial electricity, technical chemistry, mechanical drawing and machine design, strength of materials, stationary engineering and power-plant machinery, internal-combustion engine work, machine work and toolmaking, forge work, carpentry and building, patternmaking, and trade teaching for the training of skilled workmen who desire to prepare themselves for the teaching of their trades. A special feature of the work this year is the organization of a number of new courses to meet the extraordinary demands for skilled mechanics arising from the war. These courses are boat woodworking, ship drafting, marine-engine operation, and gasoline-engine operation for men desiring to enter the aviation service.

This school is now giving instruction in its evening courses to more than 1300 men who are regularly employed in various vocations and who use these courses as a means to prepare themselves for more effective service.

This will be the only public exhibit of the work of this school held this year.

A 35,000-Kw. Turbine Is Wrecked in Boston Station

About 4:55 p.m., Thursday, Feb. 14, the 35,000-kw. horizontal single-cylinder steam turbine in the O Street Station of the Boston Elevated Railways Co. exploded, so completely wrecking the machine that it will be sold for junk as it stands, it is reported. Fortunately no one was killed or injured. The trouble developed in the low-pressure stages—the 17th, it is believed. All diaphragms and wheels, together with the blades from this stage on to the 20th, were fractured and broken in many pieces and released with such force as to smash away the whole top half of the low-pressure end of the casing.

The initial cause of the accident is, at this writing, thought to be due to excessive steam pressure between the diaphragm and the 17th wheel concaving the diaphragm, causing it to foul the wheel, closing up the buckets and in this way increasing the steam pressure at this point until the next diaphragm was similarly affected, when the whole low-pressure end let go.

The accident occurred at a time when 27,500 kw. carried by engines in another station of the Railways Co. dropped their load. Assumably, the wrecked turbine tried to take all of this load, opening its secondary valve to get all the high-pressure steam available.

A member of the *Power* staff is, at this writing, in Boston endeavoring to get details of the accident.

One of the tendencies of the present day is to overdo the stop-watch and the watch-dog method. Efficiency of product does not lie in that direction. It is not right to imagine that the men have no other interest in the success of the undertaking than to watch the hands of the clock go round.

New Publications

BOILER ROOM ECONOMICS—By A. L. Potter and S. L. Simmering. Dean Engineering Experiment Station, Kansas State Agricultural College, Assistant Professor of Steam and Gas Engineering, Engineering Experiment Station Kansas State Agricultural College.

Boiler Room Economics is the title of Bulletin No. 2, originally published in 1914, but which the Agricultural College is again circulating in the hope that the contents may be of material aid in assisting in the campaign to cut down the waste in the use of coal in boiler furnaces. The bulletin gives considerable cost data, which of course need some modification at this time, owing to the changes in the market brought about by the war. The bulletin deals with boilers, pumps and injectors, feed-water heating and purification, stokers, economizers and superheaters, and the subdivisions of each of these subjects.

THE CALORIFIC POWER OF FUELS—By Herman Poole. Third edition. Rewritten by Robert Thurston Kent, M E., New York. John Wiley & Sons, Inc. Pages, 627; illustrated. Price, $3.

Since the original publication of this work in 1900 the available information upon the subject has multiplied to such an extent that its practical rewriting was necessary. This rewriting was entrusted to Robert Thurston Kent, M. E. It deals with calorimetry in four chapters, with solid, liquid and gaseous fuels in a chapter each, devoting then a chapter to the combustion of coal and another to the calorific power of coal burned under steam boilers. The final chapter treats of the analysis and measurement of the products of combustion. English units have been substituted for the metric units of the original volume. The rewriting appears to have been well done, and the book presents, in an attractive form, information that is very timely.

INTERNAL - COMBUSTION - ENGINE MANUAL. By F. W. Sterling. Published by R. Beresford, Washington, D. C., 1917. Cloth; 6 x 9 in.; 168 pages; 92 illustrations. Price, $2.

This is the fourth edition of this book; it has been completely rewritten, enlarged and brought up to date, and a chapter added on airplane engines to cover all five types of these motors. Every type of gasoline and heavy-oil engine used in the United States Navy, including those used on submarine chasers and naval launches, the Diesel and Standard types, is described.

The subject is divided into twelve chapters, taking up in order fuels, solid, liquid and gaseous; comparison of internal-combustion, and steam engines; construction; types, cycles, etc.; carburetion, the mixture, its preparation, carburetors and vaporizers; ignition and ignition systems; cooling and lubrication; governing and indicator cards; operation, troubles and remedies; gasoline, kerosene and alcohol engines, aërial motors; the Diesel, Nürnberg and Sulzer types of engines.

The work is not a book on design, but it gives a practical description of the construction and operation of the different types of internal-combustion engines. The practical way in which the subject is presented both in text and illustrations makes the work easily understood even by the uninitiated, and it should meet with favor from all those who are interested in internal-combustion engines.

TESTING CURRENT TRANSFORMERS

The Bureau of Standards has recently issued Scientific Paper No. 309, entitled "A Method for Testing Current Transformers." A general method is outlined in this paper for the determination of the ratio and phase angle of current transformers in terms of the constants of previously calibrated standard transformers of the same nominal ratio. It has been shown that such methods are essentially more sensitive or, conversely, may be used with much less sensitive instruments than the laboratory methods now in use for the absolute determination of the ratio and phase angle of a single transformer. Two of the most convenient of the many possible modifications of the general method are described in detail. It is hoped that the methods will be found useful in commercial plants where delicate laboratory equipment is not available and where large numbers of transformers must be tested rapidly and with moderate accuracy. This paper is now available for distribution, and those interested may obtain a copy by addressing a request to the Bureau of Standards, Washington, D. C.

Obituary

F. G. Rollins, late president of the Holmes Metallic Packing Co., of Wilkes-Barre, Penn., died at his home in Philadelphia on Feb 20, in his 57th year. He is survived by his wife, mother and one sister.

Personals

J. C. Bertsch has resigned his position as refrigerating engineer with the Westinghouse Electric and Manufacturing Co. Machine Works, to become established as general consulting engineer, with offices in the Monongahela Bank Building, Pittsburgh, Penn.

W. H. Thompson, for many years prominent in the heavy electric-traction work of the Westinghouse Electric and Manufacturing Co., has resigned to accept the position of works manager of the Fairmont Mining Machinery Co., Fairmont, W. Va., makers of coal-mining equipment.

W. C. Austin, auditor of the Eastern Pennsylvania Railways Co., Pottsville, Penn., has been elected assistant secretary and assistant treasurer of that company. In 1917 Mr. Austin was transferred from the staff of traveling auditors of the J. G. White Management Corporation, New York, to the accounting department of the Eastern Pennsylvania Railways Co., which company is being operated by the Management Corporation.

Engineering Affairs

The Arkansas Association of Public Utility Operators will hold a state convention at Hot Springs, Ark., May 21-23, with headquarters at the Arlington Hotel.

The Engineering Council's first annual meeting was held Feb. 21. The following officers were elected: Chairman, J. Parke Channing; first vice chairman, Harold W. Buck; second vice chairman, George F. Swain; secretary, Alfred D. Flinn. Committees were appointed as follows: Executive committee, the chairman, the two vice chairmen and David S. Jacobus, Calvert Townley, George J. Foran; finance committee, E. Wilbur Rice, Jr., chairman; Charles F. Loweth, Sidney J. Jennings, David S. Jacobus; rules committee, J. Parke Channing, chairman; Clemens Herschel, Nathaniel A. Carle, Irving E. Moultrop; public affairs committee, Charles Whiting Baker, chairman; George F. Swain, Benjamin B. Thayer, E. W. Rice, Jr., Charles E. Skinner. American engineering service, George J. Foran, chairman; George C. Stone, Alfred D. Flinn, Dr. Addams S. McAllister, Edward B. Sturgis, secretary; war committee of technical societies, D. W. Bruntno, chairman; Arthur H. Storrs, secretary; James M. Boyle, Nelson P. Lewis (American Society of Civil Engineers), Edmund B. Kirby (American Institute of Mining Engineers), A. A. Greene, Jr., R. N. Inglis (American Society of Mechanical Engineers), Harold W. Buck, Dr. Addams S. McAllister (American Institute of Electrical Engineers), Dana D. Barnum, E. C. Uhlig (American Gas Institute), Joseph Bijur, Dr. Charles A. Doremus (American Electrochemical Society), Louis B. Marks, Preston S. Milar (Illuminating Engineering Society), Christopher R. Corning, George C. Stone (Mining and Metallurgical Society of America), Henry Torrance, F. E. Matthews (American Society of Refrigerating Engineers); fuel conservation committee: L P. Breckenridge, chairman; Ozni P. Hood, secretary; Robert H. Fernald, Charles R. Richards, Charles L. Edgar, Carl Scholz, David Moffat Myers, Edwin Ludlow, Harold W. Buck.

The definition of the Engineering Council that was adopted declared that "the Engineering Council is an organization of national technical societies of America created to provide for consideration of matters of common concern to engineers, as well as those of public welfare in which the profession is interested, in order that united action may be made possible. The Engineering Council is now composed of the American Society of Civil Engineers, the American Institute of Mining Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers, having a membership of 33,000 and known as the 'Founder Societies.' "

Miscellaneous News

A Boiler Exploded on the Croffett plantation, near Bastrop, La., on Feb. 12, injuring two persons, one perhaps fatally, and wrecking the entire machinery.

A Boiler Tube Blew Out at the plant of the Sioux City (Iowa) Gas and Electric Co. on Feb. 8, injuring two firemen, one seriously. The accident necessitated shutting off the power until repairs were made.

Urges Higher Compensation for Engineers—At the conference in Washington Feb. 26, between representatives of capital and labor, held to forward the adoption of a national labor policy, a representative of the Engineering Council urged the necessity of higher compensation for engineers, to enable them to take their proper part in the nation's activities in war and peace.

An Order Authorizing the construction of a power dam at Muscle Shoals, Ala., has been signed by President Wilson, as part of the $60,000,000 project for the erection of a Government plant there for the fixation of atmospheric nitrogen for use in the manufacture of munitions and fertilizer. The site has been offered to the government without cost by the Alabama Power Co.

The Schütte & Koerting Co., of Philadelphia, has been taken over by the United States Government as an alien concern. It will be operated by A. Mitchell Palmer, alien property custodian. Adalbert Wilhelm Fischer, its former president, is now interned as a dangerous enemy alien. His wife is the daughter of Ernest Koerting, of Hanover, Germany, believed to be a near relative of the German Emperor.

An Economizer Exploded recently at the plant of the Ithaca Traction and Lighting Co., Renwick, N. Y. From an investigation of the circumstances under which the accident occurred, it develops that the economizer had been shut off from the line and the bypass used without shutting the dampers leading to the economizer, these dampers having been warped so they could not be operated. The engineer who was responsible for the explosion was instantly killed.

Business Items

C. W. Hunt Co., Inc., has moved its New York offices from 45 Broadway to the Astor Trust Building, 501 Fifth Avenue.

The H. W. Johns-Manville Co. is now comfortably installed and working full speed in its new building at St. Louis, Mo., on the southeast corner of Olive and 11th Streets.

The Cleveland (Ohio) Electric Illuminating Co. is planning on building a two-story and basement addition to its present power station on East 70th St., at a cost of about $1,000,000. A 25,000-kw. turbine will be installed.

The Westinghouse Electric and Manufacturing Co. announces the removal of its office from Phoenix, Ariz., to Tucson, Ariz. Its representatives, J. H. Knost and W. G. Willson, will have headquarters in the Immigration Building at the latter point.

The Westinghouse Electric and Manufacturing Co., East Pittsburgh, Penn., has recently secured the exclusive sales agency for the United States for Frankel solderless connectors, widely used for joining electrical wires and cables. The Westinghouse company will act also as a distributor of Frankel testing clips.

Trade Catalogs

Safety Auto-Lock Switches. Krantz Manufacturing Co., Inc., Brooklyn, N. Y Special publication No. 1585-A. Pp. 4; 8 x 11 in.; illustrated. Describes a type of safety switch manufactured by this company and also gives list prices.

THE COAL MARKET

Boston—Current quotations per gross ton delivered alongside Boston points as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 28, 1918	One Year Ago	Feb. 28, 1918	One Year Ago
Buckwheat	$4.60	$2.05—3.20	$7.10—7.35	$3.25—3.50
Rice	4.10	2.50—2.65	6.65—6.90	2.70—2.95
Boiler	3.90	....	....	....
Barley	3.60	2.20—2.35	6.15—6.40	2.35—2.60

BITUMINOUS

Bituminous not on market.

	F.o.b. Mines*		Alongside Boston†	
	Feb. 28, 1918	One Year Ago	Feb. 28, 1918	One Year Ago
Clearfields	....	$3.00	....	$4.25—5.00
Cambrias and Somersets	....	3.10—3.85	....	4.60—5.40

Pocahontas and New River, f.o.b. Hampton Roads, is $4, as compared with $2.85—2.90 a year ago.

*All-rail rate to Boston is $2.60. †Water coal.

New York—Current quotations per gross ton f.o.b. Tidewater at the lower ports* as compared with a year ago are as follows:

ANTHRACITE

	Circular[1]		Individual[1]	
	Feb. 28, 1918	One Year Ago	Feb. 28, 1918	One Year Ago
Pea	$5.05	$4.00	$5.80	$7.25—7.50
Buckwheat	4.30—5.00	2.75	5.50—5.80	7.00—7.25
Barley	3.25—3.50	1.95	4.00—4.25	4.00—4.25
Rice	3.75—3.95	2.20	4.50—4.80	5.00—5.50
Boiler	3.50—3.75	2.20	....	3.50—4.00

Quotations at the upper ports are about 5c. higher

BITUMINOUS

	F.o.b. N. Y. Harbor	Mine
Pennsylvania	$3.65	$2.00
Maryland	3.65	2.00
West Virginia (short rate)	3.65	2.00

Based on Government price of $2 per ton at mine.

*The lower ports are: Elizabethport, Port Johnson, Port Reading Perth Amboy and South Amboy. The upper ports are: Port Liberty Hoboken, Weehawken, Edgewater or Cliffside and Guttenberg. St. George is in between and sometimes a special boat rate is made. Some bituminous is shipped from Port Liberty. The freight rate to the upper ports is 5c. higher than to the lower ports.

Philadelphia—Prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide shipment are as follows:

	Line		Tide	
	Feb. 28, 1918	One Year Ago	Feb. 28, 1918	One Year Ago
Pea	$3.75	$2.80	$4.65	$3.70
Barley	2.15	1.85	2.40	2.05
Buckwheat	3.15	2.50	3.75	3.40
Rice	2.65	2.10	3.65	3.00
Boiler	2.45	1.95	3.55	3.15

Chicago—Steam coal prices f.o.b. mines:

Illinois Coals	Southern Illinois	Northern Illinois
Prepared sizes	$2.65—2.80	$3.35—3.50
Mine-run	2.40—2.55	3.10—3.25
Screenings	2.15—2.30	2.85—3.00

Smokeless Coals	So. Illinois, Pocahontas, Pennsylvania and West Virginia	Hocking, East Kentucky and West Virginia Splint
Prepared sizes	$2.60—2.85	$2.85—3.35
Mine-run	2.40—2.60	2.60—3.00
Screenings	2.10—2.55	2.35—2.75

St. Louis—Prices pet net ton f.o.b. mines a year ago as compared with today are as follows:

	Williamson and Franklin Counties		Mt. Olive and Staunton		Standard	
	Feb. 28, 1918	One Year Ago	Feb. 28, 1918	One Year Ago	Feb. 28, 1918	One Year Ago
6-in. lump	$2.65-2.80	$3.25-3.50	$2.65-2.80	$3.25-3.50	$2.65-2.80	$2.50-2.75
2-in. lump	2.65-2.80	....	2.65-2.80	....	2.65-2.80	....

2-in. screen	2.15-2.30	2.50-2.75	2.15-2.30	2.75-3.00	2.15-2.30	2.25-2.50
No. 5 washed	2.15-2.30	3.00	2.15-2.30	2.75-3.00	2.15-2.30	2.50

Williamson-Franklin rate St. Louis, 87½c.; other rates, 72½c.

Birmingham—Current prices per net ton f.o.b. mines are as follows:

	Mine-Run	Lump and Nut	Slack and Screenings
Big Seam	$1.90	$2.15	$1.65
Pratt, Jagger, Corona	2.15	2.40	1.90
Black Creek, Cahaba	2.40	2.65	2.15

Government figures.

[1] Individual prices are the company circulars at which coal is sold to regular customers irrespective of market conditions. Circular prices are generally the same at the same periods of the year and are fixed according to a regular schedule.

PROPOSED CONSTRUCTION

Calif., Ontario—The San Antonio Water Co. plans to build a power plant in the San Antonio Canyon. G. D. Smith, Mgr.

Fla., Wauchula—City plans an election soon to vote on $25,000 bonds for the erection of an electric-lighting plant.

Ga., Montezuma—J Harrison and E. M. McKenzie are considering plans for the installation of a hydro-electric plant on Whitewater Creek, 4 miles from here.

Ill., Jacksonville—The Board of Education plans to build a boiler house

Iowa, Lorimor—The Lorimor Light and Power Co. has been granted a franchise by the Board of Commissioners, to build and operate an electric transmission line in Union Co.

Iowa, Maquoketa—The Iowa Electric Co plans to extend its 33,000-volt transmission line from here to Anamosa. J. I. Reed, Gen. Mgr.

Iowa, Waterloo—The Citizens Gas and Electric Co. has been granted a franchise by the Board of Railroad Commissioners, to build and operate an electric transmission line. H. B. Maynard, Secy.

Md., Monkton—The Monkton Roller Mills Co plans to build a hydro-electric power plant on Gunpowder River to operate a proposed flour mill. Estimated cost, $25,000. O E. McCoy, Mount Washington, Pres.

Mich., Marquette—City is in the market for a waterwheel and a generator to cost about $45,000, in connection with the new electric power plant. C. Retallic, Supt T. W. Orbison, Consult. Engr.

Minn., Nashwauk—City plans to install a new electric deep well pump. Estimated cost, $7,000.

N. Y., Buffalo—The Eastern Monolithic Co., 96 South Park Ave., is in the market for electric motors.

N. Y., Greenwich—The Consolidated Electric Co. has petitioned the Public Service Commission for authority to build a 3 mi. transmission line from Northumberland Bridge through Bacon Hill and along highway leading from Bacon Hill to Grangeville. H. C Gray, Mgr.

N. Y., Utica—The Savage Arms Corporation, Turner St., is in the market for 1000 hp. power plant equipment. Noted July 31

N. C., Raleigh—The Empire Steel Co. plans to build a hydro-electric plant to operate its steel plant which will be equipped with electrically driven machinery.

N. D., Nome—City plans to install an electric-lighting plant

Ohio, Cleveland—The Cleveland Electric Illuminating Co., Public Sq., is in the market for 25,000 kw. turbine and accessory equipment. Noted July 31.

Okla., Okemah—City has plans under consideration for the erection of an electric-lighting plant.

Okla., Shattuck—City plans to install either an oil fuel or steam plant for power. J. C. Fowler, Secy., Chamber of Commerce.

Okla., Stillwater—City plans an election soon to vote on $175,000 bonds for improvements to its electric-lighting plant, etc. G M. Smith, Supt

Tex., Grapevine—The Grapevine Light and Ice Co. plans to build a new plant soon. Burrough & Harmon, Owners.

Utah, Monticello—The Blye Mountain Irrigation Co. has increased its capital stock from $15,000 to $16,000; the proceeds will be used to improve and extend its transmission line.

Utah, Provo—S. P. Stewart has applied to the State Engineer for permission to take 10 second feet of water for the electric generating plant to be erected here.

Wash., La Grande—The American Nitrogen Products Co. plans to install 3 electric ovens in its plant.

Wash., Seattle—The Board of Public Works will receive bids until March 15, instead of March 1, for the erection of a hydro-electric power plant. Estimated cost, $5,000,000. J D. Ross, Supt. of Light and Power. Noted Feb 8

W. Va., Charleston—The State University plans to rebuild its boiler house which was recently destroyed by fire.

Wis., Appleton—The Patton Paper Co. plans to build a hydro-electric power plant. J. McNaughton, Pres.

Wis., Kilbourn—The Wisconsin Power, Light and Heat Co., Milwaukee, has purchased the property of the Omro Electric Light Co., Omro, and plans to extend its Kilbourn and Price due Sac transmission lines to Berlin and Omro. J. I Beggs, 1428 1st Natl. Bank Bldg., Milwaukee, Pres.

Wyo., Wheatland—The Town is in the market for a 150 hp. engine with a 100 kw.a. generator.

Ont., Beeton—City plans to issue $15,000 bonds for the installation of a hydro-electric system.

Ont., Toronto—The Swift Canadian Co., Keel St. and St. Clair Ave., plans to build a concrete and brick addition to its boiler house. Estimated cost, $10,000.

Ont., Tottenham—City plans to install a hydro-electric system here.

Prices—Materials and Supplies

These are prices to the power plant by jobbers in the larger buying centers east of the Mississippi. Elsewhere the prices will be modified by increased freight charges and by local conditions.

ELECTRICAL SUPPLIES

KNIFE SWITCHES—Following are net prices each in cities named for knife switches mounted on slate base, front connected, punched clip type, 250 volts:

	30 Amp.	60 Amp.	100 Amp.	200 Amp.
D. P. S. T. fuseless	$0.52	$0.93	$1.90	$3.42
D. P. S. T. fused	.81	1.37	2.70	5.14
D. P. D. T. fuseless	.88	1.52	3.42	5.70
D. P. D. T. fused	1.67	2.58	5.62	9.88
T. P. S. T. fuseless	.78	1.40	2.86	5.14
T. P. S. T .fused	1.22	2.05	4.18	7.70
T. P. D. T. fuseless	1.37	2.35	5.24	8.82
T. P. D. T. fused	2.68	1.13	8.99	15.80

Lots $25 and more, list.

FUSES—Following are net prices of 250-volt inclosed fuses each, in standard packages, in cities named:

0-30 amperes	$0.11¼ each	110-200 amperes	$0.90 each
31-60 amperes	.15¾ each	225-400 amperes	1.62 each
61-100 amperes	.40 each		

FUSE PLUGS (MICA CAP) PER 100

0-30 amperes.. 4c. each in standard package quantities (500)
0.30 amperes.. 5c. each for less than standard package quantities (500)

SOCKETS, B. B. FINISH—Following are net prices in cents each in standard packages:

⅛-IN. OR PENDANT CAP			⅜-IN. CAP		
Key	Keyless	Pull	Key	Keyless	Pull
22.10c.	21.00c.	42.00c.	27.30c.	26.20c.	46.20c.

Note—Less than standard package quantities, 15% off list.

CUT-OUTS—Following are net prices each in standard-package quantities:

CUT-OUTS, PLUG

S. P. M. L.	$0.11	T. P. to D. P. S. B.	$0.24
D. P. M. L.	.18	T. P. to D. P. T. B.	.38
